Colonel CHARLES JAMES BAMBER, M.V.O., I.M.S. (ret.), died at Downpatrick on January 9, aged 86. He was born at Chittagong on July 14, 1855, the son of Mr. Henry Bamber, and was educated at Bedford Grammar School and at St. Bartholomew's Hospital, taking the M.R.C.S., L.R.C.P. in 1878 and the Cambridge D.P.H. in 1892. Entering the I.M.S. as surgeon in 1878, he became colonel in 1910 and retired in 1915. Most of his service was spent in the Punjab in civil employ, which he entered in 1887. He held various civil surgeoncies, including the important one of Rawalpindi, 1893–8, before he was appointed sanitary commissioner to the Punjab Government in 1900, a post he held until 1910. From 1910 to 1915 he was Inspector-General of Civil Hospitals in the Punjab, and held that post until his retirement. He was administrative medical and sanitary officer, Delhi Durbar, 1902–3 (medal), administrative medical and sanitary officer, Coronation Durbar, 1911 (medal), and a member of the Coronation Durbar Committee. He served on the North-West Frontier of India in the Mahsud Waziri campaign of 1881, in Burma in 1886–7 (medal and clasp), and on the North-West Frontier, Malakand, 1897 (medal); he received the M.V.O. in 1911. Colonel Bamber was the author of a work on *The Plants of the Punjab*, 1917. He had been a member of the British Medical Association for thirty-one years. He leaves a widow.

Obituary

PROF. K. F. WENCKEBACH, M.D.
Hon. F.R.C.P.

We much regret to learn of the death of Dr. Karel Frederik Wenckebach, emeritus professor of medicine in the University of Vienna, whose name as a cardiologist is honoured throughout the world. He came of Dutch parentage and was born at The Hague on March 24, 1864. After studying at the University of Utrecht he graduated M.D., and was appointed in 1888 assistant in the Institute of Zoology, and afterwards in the Department of Pathology and Normal Anatomy. In 1901 he was elected professor of internal medicine at Gröningen, and from 1911 to 1914 held the same post at the University of Strasbourg. He was then called to the chair of medicine at Vienna, and was made emeritus professor in 1929. Throughout those years Wenckebach identified himself with progress in the study, pathological and clinical, of diseases of the heart and circulatory system, publishing many important contributions to cardiological knowledge between 1901 and 1932. For some years he edited jointly with Drs. Falta and Jagic the *Wiener Archiv für innere Medizin*.

Prof. Wenckebach, apart from his scientific and professional eminence, was a man of personal charm. He spoke English fluently and felt genuine affection for this country, where he had many friends. He was an Honorary Fellow of the Royal College of Physicians and of the Royal Society of Medicine, and a Foreign Corresponding Member of the British Medical Association.

Sir THOMAS LEWIS writes:

Many of us in this country will hear with great regret of the death of Prof. Wenckebach, realizing that a chief link with a period of work of extraordinary productivity has been broken. For Wenckebach was one of that brilliant group, which included Cushny, Mackenzie, Einthoven, who simultaneously engaged, intensively and often in collaboration, in studying irregular action of the heart in man. When as a young man I first met Wenckebach it was at Gröningen, where he then held the chair of medicine. He had already reached fame by his independent analysis of cardiac irregularities, using the radial pulse only; this work, published as a whole in his first book, *Die Arhythmie*, in 1903, was a brilliant achievement and the foundation of much that followed. He continued for many years to publish important papers and to stimulate thought and work in this same field, in which he will always be recognized as having been a pioneer. In later years, by publishing an instance in which quinine stopped attacks of auricular fibrillation, he made a first observation that led quickly to the successful use of quinidine for chronic fibrillation. His work upon beriberi heart, undertaken in post-war years in the Dutch East Indies, again broke fresh ground and must be regarded as of high importance.

There are those of us who will recognize not only that a leader, but that an old friend, has passed away. "Venky," as he loved to be called by his intimates, was a genial, good-hearted fellow, full of enthusiasm for work, inspiring to others, and a great teacher of students; we remember how his work carried him from Holland to Germany and then to Austria, and how, unhappily, two war periods came to separate him from his British friends. But neither one nor the other could dim our affection or admiration for this great Dutchman.

SIR WILLIAM HORROCKS, K.C.M.G., C.B.

Colonel, late R.A.M.C.

Sir William Heaton Horrocks died on January 26 at Walton-on-Thames, aged 81. He was born at Little Bolton, Lancashire, on August 25, 1859, and educated at Owen's College, Manchester. He graduated as B.Sc. in 1878 and as M.B. with honours in 1883 at London University, also taking the B.Sc. Victoria University in 1882, the M.R.C.S. in 1882, and the D.P.H. of the London Colleges in 1901. Entering the R.A.M.C. as surgeon on February 3, 1887, he became lieut.-colonel on May 19, 1911, brevet colonel on May 20, 1911, colonel in the long war promotion list of March 1, 1915, and retired at the end of 1917. Throughout his service he was employed almost entirely on scientific work, in which he made a great name. In 1897 he was appointed assistant professor of military hygiene at the Army Medical School, Netley, and continued to hold that post at the Royal Army Medical College, Millbank, till 1903. He was medical officer and sanitary officer at Gibraltar from 1903 to 1909. In 1904–6 he served as a member of the Royal Society's commission on Malta fever, or Mediterranean fever, in which capacity he did his best work and made his name. Sir David Bruce had previously proved that the cause of this fever was a microbe, *Micrococcus melitensis,* but it was Horrocks who discovered that the disease was transmitted by goat's milk, and could be avoided by not using such milk.

In January, 1915, Colonel Horrocks was awarded the Chadwick gold medal of the Royal Society of Arts for the best work done in promoting the health of the men in the Army. When the war began in 1914 he was appointed chairman of the Anti-gas Committee to devise methods for counteracting the use by the enemy of poison gases. In 1914 he was appointed Honorary Surgeon to the King, and received the C.B. in 1917 and the K.C.M.G. in 1918. He was the author of *The Bacteriological Examination of Water,* for long the standard work on this subject, and along with Colonel Firth edited the second edition of Notter and Firth's (originally Parkes) *Theory and Practice of Hygiene.* He also edited the *Journal of the R.A.M.C.* till quite recently, and wrote many scientific treatises and articles, the list of which fills half a page in Johnston's *Roll of the R.A.M.C.* In 1894 he married Minna, the daughter of the Rev. J. C. Moore, of Connor, County Antrim; she died in 1921, leaving one son and one daughter.

Brigadier E. M. COWELL writes:

The name of Sir William Heaton Horrocks will be for ever perpetuated in the Army because of the contribution he made to the improvement of the hygiene of the Army by the introduction of the "Case, water-testing—sterilization," or, as he loved to call it, "My little box." Sir William was a great man with a wide outlook and an untiring devotion to detail. He retained his interest in the *Journal of the R.A.M.C.* until the end, being entirely responsible for the editing of all the articles since the beginning of the war. The writer had been privileged to see something of Sir William in the past few months. He was a little, frail, sweet-tempered gentleman, old in years but young in mind, living in the country but in touch with the office of his beloved journal at the War Office. He felt out of the world, and said, "Everyone has forgotten me." When told that his "little box" was in constant use and that the benefit of his discovery would last for ever, he was happy. Sir William has achieved the happiest of endings, dying "in harness."

[The photograph reproduced is by Russell, London.]

SIR PENDRILL VARRIER-JONES, M.A., F.R.C.P.

Founder and Director of the Papworth Village Settlement

The premature and sudden death of Sir Pendrill C. Varrier-Jones at Papworth on January 30 deprives the profession of a great authority whose work, though now widely recognized, he did not regard as nearly complete. Endowed with great power of work, enthusiasm, and sane imagination, he had a genius for organization.

Born on February 24, 1883, as the only son of the late Dr. C. Morgan Jones, he was educated at Epsom College, St. John's College, Cambridge (foundation scholar), where he was placed in the first class of the Natural Sciences Tripos, 1905, Part I, and in the second class of Part II in the following year, and at St. Bartholomew's Hospital, where he was house-physician. Then as a research worker at Cambridge, dealing with the temperature of patients throughout the twenty-four hours, he temporarily acted as tuberculosis officer for Cambridgeshire, and then realized the farce of giving advice, such as light work in the open air and a good diet, to a man with pulmonary tuberculosis who could not secure these benefits. Accordingly in 1915 with the encouragement, and their collaboration in published papers, of Sir Clifford Allbutt and Sir German Sims Woodhead, he opened at Bourn, at first with one patient, the Cambridgeshire Tuberculosis Colony, which in 1918, with twenty-five patients, moved to Papworth Hall, the colony of which now contains 1,200 residents in hospitals, hostels, and cottages, 500 being in hospitals. Here for twenty-two years there followed remarkable and constant additions: a surgical hospital and unit for tuberculous disease, other hospital blocks, a home for tuberculous nurses, research laboratories with a *Bulletin,* and especially the fine workshops where workers with arrested lesions work under medical care. He was a good judge of his assistants, trusted them, and attached them to himself for many years. In a letter written on January 15 last Varrier-Jones said that the sales of the Papworth industries exceeded those of the record year 1939. He was always on the watch for advances and new lines of activity, and was looking forward to the establishment of a school of tuberculosis at Papworth. He did much to help similar colonies for subnormal men —such as Enham (now allied with Papworth), Preston Hall treatment and training colony for tuberculous ex-Service men, near Maidstone, Peamount village settlement, near Dublin—and had much at heart the wide extension of this method of dealing with tuberculosis.

At the time of his death he reached the summit of his career, and had received the recognition he so thoroughly deserved. He was knighted in 1931; at the Royal College of Physicians of London he was elected a Fellow in 1934, gave the Mitchell Lecture on the subject of village settlements for the tuberculous in 1927, and was awarded the Weber-Parkes prize for tuberculosis in 1939. Medical men from distant parts constantly visited Papworth, and Varrier-Jones would have been the Government's representative at the meeting in Berlin arranged for September, 1939, of the International Union against Tuberculosis. The Duke of Kent has been president of Papworth since 1935, and six members of the Royal Family are its patrons.

HUMPHRY ROLLESTON.

It will be of interest to readers to know that Varrier-Jones at the time of his death was actively engaged in developing a scheme to add teaching to his other work. He proposed to hold a course of instruction in the diagnosis and treatment of

pulmonary and other forms of tuberculosis at Papworth Village Settlement. The course would include instruction in clinical methods, radiology, and chest surgery, and special attention would be given to the sociological and economic aspects of the disease.

Sir ARTHUR MACNALTY writes:

It is with great sorrow that I hear of the death of my friend, Pendrill Varrier-Jones. It is hard to realize that a man of such genius, courage, and enthusiasm for the welfare of the consumptive has left us, harder still to realize what Papworth can be without him, for he was in a very special sense the personification of the great institution which he founded. But Papworth is much more than an institution; it embodies the secret of successful treatment of tuberculosis. Varrier-Jones, with the rare insight of the pioneer, saw tuberculosis as a social and economic problem as well as a medical one, and at once began to seek a solution. The axioms on which his work was founded were simple. His experience as tuberculosis officer in Cambridge showed him that the consumptive worker was in the majority of cases a damaged life, that through sanatorium treatment he frequently obtained arrest of his disease, but when exposed to the strain and stress of competition with healthy labour he broke down and his last state was worse than the first. He became unemployed, a charge upon the State, and, what was worst of all, he lost hope. As Sir Clifford Allbutt said, the work of Varrier-Jones was to restore that hope. The consumptive at Papworth remains under medical supervision. He passes through the stages of hospital and sanatorium treatment, and is provided with occupation suited to his state of health. When afebrile he works at a trade, for which he receives trade union rate of wages. He resides in a hostel or, if married, in the village settlement with his wife and family. If at any time his health relapses he is sure of prompt and expert treatment in the institution.

"Who hath despised the day of small things?" Varrier-Jones started his village settlement at Bourn in Cambridgeshire in 1915, with one patient in a shelter. He saw this nucleus develop into a great institution at Papworth with 500 acres of land, administrative blocks, hospital blocks provided with every facility for modern treatment, a large sanatorium section, laboratories and research institute, a village settlement of a hundred cottages and more, hostels for men and women, and factories equipped with labour-saving machinery, with annual sales amounting to well over £88,000 per annum.

Sir Robert Morant did much to help on the scheme in its early days, and the Ministry of Health made monetary grants. In 1919–20 Varrier-Jones, Dr. Nathan Raw, M.P., and I constituted a small departmental committee which was set up to explore the possibilities of establishing village settlements for tuberculous ex-Service men throughout England and Wales. We paid many visits to possible sites and conferred with a number of local authorities. In the end it was considered better to develop existing settlements at Papworth and Preston Hall than to provide new organizations. Papworth alone did not occupy Varrier-Jones's boundless energies. He was honorary medical director of the Enham Village Centre for ex-Service men, replanned the Preston Hall Village Settlement at the request of the British Legion, and advised on the establishment of a village settlement at Peamount near Dublin. A firm and kindly administrator, he had a profound knowledge of men and business affairs, which greatly contributed towards the success of Papworth. He was, indeed, a "captain of industry" who employed his gifts solely for the benefit of the consumptive worker. I have never known a man of greater single purpose. He devoted his rare holidays for the most part to visits abroad in order to study foreign problems of tuberculosis. He was ever planning new departures to meet the existing situation. Only a few days ago I received a letter from him outlining a scheme for undergraduate instruction in tuberculosis. "If necessary I shall start with one student," he wrote characteristically.

He was a generous host and a witty companion, with a keen sense of humour. Those who considered him intolerant misunderstood him. It was zeal to reach his goal that made him press on and sometimes show impatience. Varrier-Jones's place in the history and development of anti-tuberculosis work is a very high one, and mankind has lost one of its benefactors.

F. TEMPLE GREY, M.B., CH.M., M.R.C.P.

We regret to announce the death of Dr. F. Temple Grey, barrister-at-law, which took place in London on January 23. He had made a place for himself in the two professions of law and medicine. He was as much at home in the Grotius Society wrestling with the intricacies of international law as he was in the pathological department of the hospital which he dearly loved, the Princess Elizabeth Hospital for Children at Shadwell. His death, at the age of 54, following a long illness, has cut short a career of great promise.

Francis Temple Grey was born in London in 1886, the son of an officer in the British Army in India. He was educated privately, and afterwards entered Wadham College, Oxford, at which university he took his M.A. Later he went to Australia, and it was there in 1914, at the University of Sydney, that he qualified in medicine. For a time he served as house-surgeon and resident pathologist at the Sydney Hospital, afterwards becoming a surgeon in the Royal Navy during the last war, when he was decorated for gallantry on service in the Dardanelles. Returning to this country after the war, he was for six years pathologist to the Ministry of Pensions. Gradually he built up a reputation as an authority on certain branches of medical jurisprudence, and was an expert witness in several criminal trials in which the question of death by poisoning was the issue. He was deputy coroner for the Eastern Division of Middlesex, also honorary pathologist to the East End Maternity Hospital. In 1924 he was "called" at Lincoln's Inn. His outstanding work on the legal side was his editorship of the fifth edition of Pitt Cobbett's *Cases in International Law*.

A man of frail physique—though that did not prevent his participation in strenuous sports like swimming and yachting—Dr. Grey was a man of acute intellect and considerable gifts of teaching and exposition. The smaller the class to which he lectured at the Princess Elizabeth Hospital, and the scantier the attendance at small medical societies which he addressed in and around London, the more he seemed to expand. His quick mind, his clear diction, and his illustrations from his growing experience of unusual medico-legal cases made his informal lectures both fascinating and instructive. He was a quiet but effective worker for the British Medical Association, which he had first joined in Australia in 1915. On returning from service after the war he threw himself into the activities of the Marylebone Division, of which he was honorary secretary for some years, and chairman in 1937–8. He also served as the representative of his Division at the Annual Representative Meetings from 1927 to 1936, with one or two exceptions, and his interventions in debate, which were generally on medico-legal or ethical subjects, were always worth listening to, especially when he took an unpopular view, as he not infrequently did. He was a member of some headquarters committees, notably the Committee on Lunacy Law and Mental Disorder from 1928 to 1930, the Science Committee from 1929 to 1931, and the Library Subcommittee from 1929 until his death. He was the originator of an improved technique for blood transfusion. His articles in the medical journals were largely on the subject of diphtheria, on the bacteriological aspects of which he had specialized. The articles on "Medical Jurisprudence," "Legal Aspects of Insanity," and "Capital Punishment" in the current *Encyclopaedia Britannica* were also from his pen.

W. CECIL BOSANQUET, M.D., F.R.C.P.

Consulting Physician to Charing Cross and the Brompton Hospitals

Dr. William Cecil Bosanquet, who died in London on January 24 at the age of 74, was well known as a general physician and pathologist and for his interest in tuberculosis and other diseases of the chest.

He was born at Whiligh, Sussex, on October 12, 1866, son of Admiral G. S. Bosanquet, and from Eton, where he was a King's Scholar, he went up to New College, Oxford, taking a first class in Classical Moderations in

1887 and a first class in *Lit. Hum.* in 1889. From 1891 to 1897 he held a Fellowship of New College, during which time he studied medicine at Charing Cross Hospital. He took the M.A. degree at Oxford in 1892 and the M.B. and M.D. in 1897, and was elected F.R.C.P. in 1904. At Charing Cross Cecil Bosanquet was in turn pathologist, assistant physician, and full physician, and he was for many years physician to the Brompton Hospital for Consumption. He had also been physician to out-patients at the Victoria Hospital for Children, Chelsea, and physician to the London Lock Hospital. During the last war he was attached for two years to the *à la suite* staff of the 4th London General Hospital with the rank of major R.A.M.C.T., and thereafter served with the 44th General Hospital in India, and was consultant physician to the North-West Frontier Force in 1919. At the Royal College of Physicians he was examiner in 1923–7, a member of Council 1927–9, and then Censor for a year. At the Annual Meeting of the British Medical Association in 1904 at Oxford he was honorary secretary of the Section of Medicine.

Bosanquet wrote jointly with Prof. Eyre a small work on serums, vaccines, and toxins in treatment and diagnosis which reached a third edition in 1916, and collaborated with Mr. H. S. Clogg in a publication on the stomach, intestines, and pancreas. He also edited the thirteenth edition of *Green's Pathology and Morbid Anatomy*. In 1937 he published an interesting book under the title *Meditatio Medici: A Doctor's Philosophy of Life*; it bore the marks of wide reading and much reflection, well phrased in scholarly English.

Dr. MAURICE DAVIDSON writes:

It is difficult to do justice to the memory of Bosanquet's personality. His private life was remote from his professional activities, and few, if any, of his medical friends were permitted really to see behind the veil. His refinement of intellect and exquisite scholarship were apparent to all who associated with him in hospital; these were, perhaps, the most conspicuous elements in the personal charm which endeared him to his colleagues, but behind him and beyond them lay something rarer—a real unselfishness and a deep consideration for the feelings of others. It is, perhaps, in moments of physical weakness that such qualities are sometimes seen to stand out in clear relief. During the last few weeks of a distressing illness nothing was more in evidence than Bosanquet's innate gentleness and courtesy, which seemed to show themselves more and more as his bodily strength grew weaker. Indifferent to his own feelings and to the consciousness of failing powers, he thought only of those around him and of how he could still be to them the kindly and gracious host that he always was. The writer has occasion to recall with gratitude the kindness and attention received at Bosanquet's hands during a long illness some years ago, and in memory of this to mourn the passing of a great gentleman, whom he was also privileged to look on as a personal friend.

The death occurred at his home, St. Anns, Carlisle, on January 13, of Dr. GEORGE DUNCAN LOGAN, who for over forty years was in practice at Ecclefechan, Dumfriesshire. He was born of Border farming stock at Balmacara in the West Highlands in 1859, and was educated at George Watson's College, Edinburgh. Keen on athletics, he boxed and played football, and his name appears in about a third of the entries for the events at the first school sports of that institution. He then entered Edinburgh University and graduated M.B., C.M. in 1882, proceeding M.D. in 1915. After acting as house-physician and house-surgeon at the Royal Northern Infirmary, Inverness, and gaining experience in psychiatry at Derby County Asylum and the Murray Royal Institution at Perth, he became an assistant in practice in Cumberland and later went into practice on his own account in Ecclefechan. He had been a member of the British Medical Association for thirty-nine years. T. McL. G. writes: A man of exceptional ability and outstanding personal qualities, Logan's fame spread far beyond the borders of his village, and his practice gradually became one of the largest in the country. He became known and respected by consultants in Edinburgh, London, and Glasgow, and had many interesting tales of the giants of the medical past. As a student he had "sprayed" for Lister, and assisted at the first operation for removal of an ovarian cyst done in Edinburgh. The patient was a Highland girl whose only language was Gaelic, which was that of Logan's childhood, and he acted as interpreter. He retired from practice in 1925, and after a year or two in other places he bought St. Anns, with its beautiful gardens, in which he spent many happy hours at his favourite hobby, gardening, at which he was very expert and of which his knowledge was encyclopaedic. He was widely read in other subjects beside his own, and excelled at fishing and shooting. In the days when night journeys were done in open horse-drawn vehicles he studied the stars, and knew a vast amount of astronomy. By day he studied birds, and had many wild birds sufficiently tamed to eat from his hand and his pocket. An interesting conversationalist and a charming host, he made his home a place "that liked to be visited." Three years ago he celebrated his golden wedding. He is survived by his widow, and by a granddaughter and great-grandson who are in South America.

Dr. JOHN DUDGEON GILES, O.B.E., medical superintendent of Hope Hospital, Salford, was killed by enemy action in December, 1940. He was the son of the late Rev. Alexander Giles of Ashkirk, Selkirkshire, and was educated at the University of Edinburgh, where he graduated M.B., Ch.B. in 1903. He proceeded M.D. in 1909, being commended for his thesis. He also studied in London at King's College and Middlesex Hospitals. After graduating he served as assistant medical superintendent of Bermondsey Parish Infirmary, as resident medical officer of Middlesbrough Union Hospital, and as medical superintendent of South Shields Union Infirmary. At Salford, in addition to being in charge of the Hope Hospital, he was medical officer of Salford Old People's Homes and consulting medical officer to the Salford Municipal Maternity and Babies' Hospital. He had been a member of the British Medical Association for twenty years.

Dr. JAMES THORESBY JONES, J.P., who died at Antrim Mansions, London, W., on January 20, aged 90, had been a member of the British Medical Association for fifty-three years. A student of University College and Hospital, London, he qualified as M.R.C.S.Eng. in 1877, obtained the L.R.C.P.Ed. soon afterwards, and took the M.D. degree of Durham University in 1894. As a young man he served as house-surgeon at University College Hospital and at St. Bartholomew's Hospital, Rochester. Settling in practice in London he became surgeon to the Western General Dispensary and to the Post Office and Board of Education, and district surgeon under the L.C.C. and the Metropolitan Water Board; he was also for many years physician to the School for Mothers and Child Welfare at Paddington. Dr. Thoresby Jones was a regular attendant at the meetings of the Medical Society of London, and had held office as president of the Harveian Society.

Dr. THOMAS VINCENT DICKINSON, a former Master of the Society of Apothecaries, died in London on January 21, aged 83. The son of a medical man, Dr. Dickinson was a medical student at King's College, London, and at St. George's Hospital, and qualified M.R.C.S. in 1879 and L.R.C.P. in 1880. His qualification by no means ended his student career, for within the next year he had taken the London M.B., with honours in physiology and histology, and in the following year the M.D. His specialty was the diseases of women and children, on which he wrote a number of papers in the medical journals. Early in his career he became attached to the Chelsea Hospital for Women, and served that institution as a member of its visiting staff for many years. From 1892 until 1897 he was an examiner in obstetrical medicine for the Society of Apothecaries, and thus began a close association with that body which culminated in his election as Master for 1925–6. During the war of 1914–18 Vincent Dickinson, who received special mention for his services and was made a Commander of the Crown of Italy, served on the Italian Government Medical Commission from the time of Italy's entrance into that war on the side of the Allies until the

armistice. His services were highly valued by pre-Fascist Italy, and to the cause of Anglo-Italian co-operation Dr. Dickinson continued to devote himself with great enthusiasm. He was, first, physician, and afterwards consulting physician, to the Italian Hospital in London, and he was the founder of the Anglo-Italian Literary Society. He also gained the medal of the Royal Society of Arts for Italian. After the end of the last war he served for fifteen years, until 1933, as chairman of medical boards under the Ministry of Pensions. He was also medical adviser to the Admiralty Welfare Department. To the end of his life he held the post of visiting apothecary to his old hospital, St. George's. His contributions to medical society life were mostly made to the Chelsea Clinical Society, of which he was at one time president, and to the History of Medicine Section of the Royal Society of Medicine, of which he was a vice-president.

Dr. JOHN JAMES ADAMS of Ashville, Antrim, has died in his ninety-second year. He was appointed coroner for the Antrim district in 1886, and on completion of fifty years' coronership a number of his friends presented him with his portrait in oils. Dr. Adams was educated at Queen's College, Belfast, graduating M.D. of the Royal University of Ireland in 1875, and M.Ch. in 1877. Respected as a man of sterling character and a fearless critic, he was also noted for his practical benevolence; the town and district have many memorials of his public spirit and generosity. At an inquest in the board room of Antrim Union the deputy coroner, Dr. Hall Stewart of Randalstown, paid a high tribute to the work and personality of Dr. Adams, saying that he was beloved not only by his professional colleagues but also by that wide circle of patients and friends with whom he came into contact. Dr. Adams was one of the outstanding figures in the public, social, and charitable life of Northern Ireland, and they were the poorer because of his passing. As a coroner he was most acceptable to everyone concerned, for he was genial, approachable, and thoroughly human.

Dr. DANIEL CHRISTOPHER MULLALLY, who died with tragic suddenness on January 27 from pulmonary embolism following an operation, was only 26 years old. He graduated M.B. of Queen's University, Belfast, in 1936, and last year, in spite of the handicap of ill-health, passed the examinations for M.D. and M.R.C.P.Lond. During 1939 he was house-physician in the National Temperance Hospital, and subsequently blood transfusion officer there, under the E.M.S. His work (writes J. B. Y.) was of the best. He had great gifts and qualities of mind and character which seemed to mark him out for future distinction in the profession. Medicine can ill afford to lose one of such promise, and his early death is indeed a tragedy.

Universities and Colleges

UNIVERSITY OF LONDON

The following candidates have been approved at the examinations indicated:

DIPLOMA IN CLINICAL PATHOLOGY.—G. Prasad, J. H. Stritch, Freida Young.

BRITISH POSTGRADUATE MEDICAL SCHOOL

ACADEMIC POSTGRADUATE DIPLOMA IN CLINICAL PATHOLOGY.—A. R. Aidin, J. W. Clegg, J. T. Quinlan.

Diploma in Psychological Medicine

The last date for obtaining the entry form for the examination for the postgraduate diploma in psychological medicine, March–April, 1941, is February 24; entry closes on March 1; and the examination begins on March 25 (Part A) and April 8 (Part B). Entry forms may be obtained from the University Extension Registrar, University of London, Royal Holloway College, Englefield Green, Surrey.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

At the quarterly Comitia of the Royal College of Physicians of London, held on January 30, with the President, Sir Robert Hutchison, in the chair, the following representatives of the College were elected: Sir Charles Wilson, Dr. H. L. Tidy, Prof. J. A. Ryle, and Prof. H. P. Himsworth on the British Medical Association Medical Planning Commission; Dr. A. Feiling on the Council of the Queen's Institute of District Nursing; Dr. A. S. Barnes on the Court of Governors of the University of Birmingham; Dr. P. Hamill on the Advisory Committee of the Ministry of Health to compile a War Emergency Formulary.

Membership

The following candidates, having satisfied the Censors' Board, were admitted Members of the College:

James Brown Arthur, M.B.Ed., John Donald Bail, M.B.Lond., Thomas Edward Dowrick Beavan, M.B.Birm., Aaron Jacob Bernfield, M.B.Lond., Stanford Cade, F.R.C.S., William Edward Clarke, M.B.Lond., Constance Elaine Field, M.D.Lond., Michael Oliver John Gibson, M.B.Camb., Alfred Gordon Heppleston, M.B.Manch., Hugh Martin James, M.B.Camb., Raymond Benedict Magill, M.B.Belf., Robert Hereward Mole, M.B.Oxf., Narayan Vasudeo Nene, M.B.Bomb., Elizabeth Herman Rosenberg, M.B.Lond., Gerard Sanderson, M.B.Liverp., Shital Prasad Sinha, M.B.Patna, Geoffrey Reginald Steed, M.D.Lond., Clive Henry Critchett Upjohn, M.B.Camb., Charles Keith John Vautier, M.B.New Zeal., Celia Kathleen Westropp, M.B.Oxf.

Licences and Diplomas

Licences to practise physic were granted to the following 177 candidates (including 22 women) who had passed the Final Examinations in Medicine, Surgery, and Midwifery of the Conjoint Board, and have complied with the necessary by-laws:

J. P. Adlam, B. Alexander, A. J. C. Allen, G. J. Amiel, A. W. Anderson, C. M. Arango, A. Arnstein, M. W. Arthurton, W. Aspinall, Islay C. Barne, J. Barrow, D. H. Bennett, F. A. Binks, A. Bogdanovitch, C. Brun, J. M. Burbury, C. R. K. Carroll, D. I. Chapman, H. R. Claff, L. Cohen, Brenda Collar, C. W. Coplans, J. A. B. Cotsell, W. R. Cyrlas-Williams, J. H. Dadds, E. B. Dawe, J. Denfield, G. D. Denlow, A. G. Doughty, C. E. Drew, Margaret D. D. Dudley-Brown, C. T. F. Ealand, W. K. Earle, H. H. G. Eastcott, Christine Ecroyd, E. M. Ensor, E. G. Essery, Joan Fitzherbert, B. J. Fowler, A. J. Fraser-Simson, S. M. Frazer, F. Freund, P. D. Gange, O. F. Garar, L. Garland-Collins, A. J. Gaskell, J. E. Gilbert, R. A. Gill, B. M. Girgis, G. Godfrey, A. H. F. Gow, C. N. Grainger, J. C. Gray, J. L. Greaves, Barbara J. Greenwood, C. H. Greer, A. G. Gregory, E. W. Guillaume, J. W. P. Gummer, A. W. Hagger, F. A. H. Hall, Winefride M. Hamilton, G. P. Hartigan, P. L. M. Hartley, M. C. Head, E. H. Hemsted, G. G. Henn, M. Hershman, J. H. Hicks, A. C. Higgett, G. de B. Hinde, J. C. Holman, Emily M. Horsfall, E. W. Hyde, N. N. Iovetz-Tereshchenko, J. D. James, Elizabeth E. Johnson, A. C. V. Jones, H. W. Jones, H. P. Jones, H. O. Jones, R. D. Jordan, H. L. Joyce, H. Kanter, Marie D. Kelleher, R. E. Kelly, E. R. Keyworth, J. H. Kirkham, S. H. Kutar, R. U. F. Kynaston, B. Lewis, D. W. Liddell, Isobelle G. Little, R. R. H. Lovell, N. W. R. Lucas, Silvia C. Lucas, W. C. Lyon, G. E. McFall, W. E. Mahon, J. Manhas, F. R. C. Manning, L. W. C. Massey, T. R. Maurice, Joyce B. M. Mayes, F. B. Meade, V. C. Medvei, Joan S. Millett, A. F. Mohun, R. A. R. Montgomery, J. V. Morris, Madeleine B. Morris, J. H. MacL. Munro, S. Muntarbhorn, T. A. Narayanan, L. P. A. Newborne, D. J. O'Brien, W. O'Brien, C. B. O'Carroll, E. E. Oddie, F. H. Packer, R. H. A. Parker, C. N. Partington, A. J. Patenall, G. H. Pearson, Rosa M. Pigot, L. Portelli, F. T. G. Prunty, S. D. Purcell, H. Reeback, H. N. Reed, P. A. Rees, R. L. Rees, R. E. Renaud, G. K. C. Rettie, R. E. Rewell, Florence C. R. Richardson, Kathleen P. Richardson, M. J. Riddell, E. F. Ridley, R. Robins-Browne, G. K. T. Roche, J. A. J. Sandilands, W. Schey, Isabel B. Schooling, C. M. Shafto, R. G. Sheppard, J. C. Smith, R. J. Stanley, R. B. Stark, T. Sternberg, J. N. Stirling, H. A. W. Stormont, R. J. Stout, F. G. Strong, P. N. Swift, J. M. Swithinbank, M. R. Thompson, D. N. Thornton, R. Tilley, St. J. M. A. Tolhurst, S. Tomback, Eileen D. Trafford, Ruth D. Usher, P. C. van der Westhuizen, A. S. Veeder, J. H. E. Verdon, G. B. R. Walkey, F. J. H. Walters, W. R. Watson, S. D. V. Weller, B. W. Wells, Moyra Welply, H. Whittaker, R. D. Wilkins, R. J. G. Williams, A. R. H. Williamson, J. B. Wyman.

Diplomas were granted, jointly with the Royal College of Surgeons of England, as follows:

DIPLOMA IN PUBLIC HEALTH.—G. P. Charles, Gwendoline M. Edwards, Joan M. Faulkner, S. Leff, I. B. Sen Gupta.

DIPLOMA IN MEDICAL RADIOLOGY.—B. Jolles, J. H. Wilding.

Diplomas in Anaesthetics were granted to the twenty-eight persons whose names were published in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of December 21, 1940 (p. 888), as were the names of the four persons who were granted Diplomas in Laryngology and Otology. Diplomas in Psychological Medicine were granted to the three persons whose names were published in the report of the meeting of the Royal College of Surgeons of England in the *Journal* of January 18 (p. 101).

Medical News

We publish in the *Supplement* this week (p. 15) the tenth list of donations to the Medical War Relief Fund. It reflects once again the practical sympathy of medical men in the British Dominions and Colonies for their colleagues in this country who have suffered loss or deprivation through the war. Medical officers of the Basutoland Government Service who cannot be released for active war service have now added their contributions to the subscriptions and collections which have arrived from Australia, Canada, South Africa, the Gold Coast, and Assam.

The Tavistock Clinic (Institute of Medical Psychology) has arranged a discussion on the shelter problem, to be held at Westfield College, Kidderpore Avenue, N.W.3, on Saturday, February 15, at 2.30 p.m. It will be open to registered medical practitioners free of charge, and those wishing to attend are asked to notify the Educational Secretary at Westfield College.

At a meeting of the Pharmaceutical Society of Great Britain at 17, Bloomsbury Square, W.C., on Wednesday, February 12, at 2.30 p.m., an address entitled "Early English Materia Medica Cabinets in Cambridge" will be given by Mr. E. Saville Peck, M.A., member of council. There are three of these cabinets in Cambridge—namely, Vigani's at Queens' College, Addenbrooke's at St. Catharine's College, and Heberden's at St. John's College—the earliest dating from 1701.

Lord Horder, chairman of the Empire Rheumatism Council, has received from the President, H.R.H. the Duke of Gloucester, a letter acknowledging receipt of the encouraging report for 1940, and conveying his congratulations on the good work of the past year and confident hopes of full success in the future.

The Davyhulme Military Hospital Medical Society held its inaugural meeting at the hospital on Thursday, January 30, when Major R. W. Fairbrother read a paper on cerebrospinal meningitis. The object of the society is to encourage the meeting together of medical men and women in all the Services (including civilian) for the discussion of problems of common interest. Membership is open to any medical man or woman in the area. The next meeting will be held at the hospital on Thursday, February 13, at 3 p.m., when Lieut.-Colonel W. E. Underwood will read a paper on gunshot wounds in the field. Will anyone interested kindly get in touch with the hon. secretary, Major William Brockbank, Military Hospital, Davyhulme, near Manchester.

The Ministry of Health has ordered half a million "germ masks" to be supplied to public air-raid shelters for issue to people as a protection against the spread of epidemic catarrhal diseases by droplet infection. The standard type of mask is made of non-inflammable cellulose acetate film, 5½ in. square, to which is attached a narrow strip of elastic so that the film, placed across the bridge of the nose, is held in position by putting the elastic band over the head. This type, apart from being made for free issue, can be obtained from most chemists' shops for 2d. or 3d. Satisfactory substitutes can be made at home from transparent paper or oiled silk.

An intensive campaign for the education in health matters of people using air-raid shelters as dormitories is already well under way. A supply of two posters for display in surface and in large public shelters is being sent to local authorities by the Ministry of Health, and the Central Council for Health Education, at the Ministry's request, is preparing leaflets and posters which will be available to all local authorities. Some of the Central Council's leaflets, notably that on "Shelter Health," have already been distributed. In a recent circular from the Ministry local authorities are asked to make use of the Central Council's facilities, and to get in touch with them with a view to making appropriate arrangements. They are also informed that in allocating the two posters now being sent to them up to 50% of the sites in shelters should be used for (1) other Ministry posters relating to help after air-raid damage or to advice about rest centres, and (2) posters from the Central Council.

Medical Notes in Parliament

Science and Government

At the annual meeting of the Parliamentary and Scientific Committee at the House of Commons on January 28 the Earl of Dudley was elected president for 1941 and Prof. A. V. Hill a vice-president. In an address to the committee Prof. A. V. Hill said safeguards must be maintained to ensure the independence and integrity of science in the increased volume of State-aided research. He would like to see introduced into each Department or organization some Scientific Advisory Council similar to that now working so well in the Ministry of Supply. There should be regular interchange of personnel between Government research establishments, organizations, universities, and other independent institutions in which research was done. Some kind of "family doctor" was needed to watch over the scientific health of Government Departments, who would call in consultants when and where needed. One of the great tasks lying before scientific people after the war would be to rebuild on a firmer foundation the international scientific organizations. With regard to international co-operation, Prof. Hill referred to the difficulties which had arisen in the past through political considerations being introduced into what should have been purely scientific gatherings. After the war we should rely so far as possible on the help and advice of our American scientific friends.

Diphtheria Inoculation.—Miss HORSBRUGH told Mr. Brooke on January 22 that available information suggested that the appeal for parents to have their children inoculated against diphtheria had, in many areas, met with a good response from parents and local authorities. It was too early to assess the measure of success achieved. She promised Sir Stanley Reed that she would make inquiries if she were sent details of an organization which, according to Sir Stanley, was trying to persuade parents not to have their children inoculated.

Chronic Sick in London Hospitals.—Mr. MACDONALD told Mr. George Strauss on January 23 that the number of old and chronically sick cases in the London hospitals had been very much reduced, and was less than half the normal. Many of those who remained had expressed unwillingness to go. Top floors and other particularly exposed parts of the hospitals were not in use, and casualties had been few. It was not practicable at the present time for all the remaining chronic sick to be moved out in view of the heavy calls made on the outer beds by acute sick, air-raid casualties, and Service cases.

Scabies.—Sir ALFRED KNOX suggested on January 23 the making of regulations under the Public Health Act, 1936, to provide for the notification of scabies. Mr. MACDONALD answered that scabies was a skin condition produced by the burrowing into the skin of a parasite. It was not, therefore, an infectious disease in the accepted sense. Many cases never came under the notice of a doctor. Compulsory notification was not the most suitable method of dealing with the problem. Sir ALFRED KNOX stated that since evacuation began one of the boroughs in the Wycombe division of Buckinghamshire had had 150 cases.

R.A.M.C. and Treatment of Air-raid Casualties.—Co-operation of the R.A.M.C. in the work of treating casualties in bombing raids has been agreed in principle and has in considerable measure been put into force, particularly in the case of specialist officers. In some cases R.A.M.C. orderlies have assisted in the initial treatment of civilian casualties. Captain Margesson and Mr. MacDonald are continually reviewing the position with a view to increasing the co-operation between military and civilian medical officers.

Alternatives for Imported Drugs.—Mr. MACDONALD told Sir Francis Fremantle on January 30 that a Regulation had been made to limit the prescription by medical practitioners of non-essential imported drugs and the sale of such drugs as ingredients in imported medicines. Suitable alternative materials would be provided for prescription. The Regulation would be published in a few days. He intended to give advice to general practitioners in this matter, details of which would appear in the medical journals.

Calcium Deficiency.—Major LLOYD GEORGE, in a reply to Sir Ernest Graham-Little on January 30, said there were reasons for distrusting the conclusions by the Liverpool Institute of Research that there was no general deficiency of calcium in the people's diet and danger in increasing the calcium content of bread. The results of this research were under consideration on behalf of the Medical Research Council. The Ministry of Food still proposed to add calcium to the reinforced loaf.

EPIDEMIOLOGICAL NOTES

Influenza in Week Ending January 25

The increase of influenza deaths from 99 to 120 (see tables below) is not startling. Taking, however, a figure of about 100 as evidence of the beginning of prevalence, great or small, we have had two instances of severe epidemics in which the first pair were virtually the same as this—namely, in 1929, when 99 was followed by 122 and the eventual maximum was 2,183; and in 1932–3, when 85 was followed by 120 and the eventual maximum was 1,934. On the other hand, after 94 last year the next figure was 158, but the maximum was only 629. It may be added that certain more recent information for London supplied to the Ministry of Health is somewhat reassuring, as it shows that there has been no further increase in the numbers of admissions of influenza, bronchitis, and pneumonia to hospital. The conclusion is that there is no immediate sign of danger, but we cannot yet give an optimistic forecast. The age distribution of the influenza deaths is of the normal inter-pandemic type.

Total of Influenza Deaths and Deaths in Age Groups in 126 Great Towns for Week Ending January 25

All Ages	A Under 1 year	B 1–5	C 5–15	D 15–25	E 25–35	F 35–45	G 45–55	H 55–65	I 65–75	J 75 and over

Cerebrospinal Fever

Although the number of notifications of cerebrospinal fever increased in the whole country, the number of administrative areas notifying cases fell from forty-four to forty-one, and, with the exception of the West Riding of Yorks, where cases rose from 5 to 26, virtually the same areas were affected—namely: Lancaster 30 (Liverpool 10, Manchester 4, Bacup 2, Barrow-in-Furness, Blackpool, Bolton, Bootle, Burnley, Bury, Preston, Ashton-under-Lyne, Crosby, Fleetwood, Lancaster, Morecambe and Heysham, Huyton with Roby U.D., and Whiston R.D., 1 each); Yorks, West Riding, 26 (Sheffield, 9, Leeds 8, Bradford 2); London 14; Warwick 14 (Birmingham 11, Coventry, Leamington, and Rugby, 1 each); Gloucester 13 (Bristol 5, Gloucester 4, Cirencester R.D. 2, and 1 each in Stroud U.D. and R.D.); Essex 11 (West Ham 3, East Ham 2, and 1 each in Colchester M.B., Ilford M.B., Romford M.B., and the urban districts of Brentwood and Thurrock, and the rural district of Halstead); Surrey 11 (2 each in Guildford, Kingston, and Wimbledon, and 1 each in Epsom and Ewell M.B., Mitcham M.B., Sutton and Cheam M.B., Woking U.D., and Hambledon R.D.); Chester 8 (Birkenhead 2, Chester 2, and 1 each in Wallasey C.B., Bebington M.B., Wilmslow U.D., and Runcorn R.D.); Glamorgan 8 (1 each in Cardiff, the urban districts of Aberdare, Caerphilly, Llwchwr, Maesteg, and Port Talbot, Rhondda, and the rural district of Cowbridge); Southampton 8 (Portsmouth 3, Southampton 2, and 1 each in Bournemouth C.B., Aldershot M.B., and Eastleigh M.B.); Stafford 8 (Smethwick 2, and 1 each in Burton-on-Trent, Stoke-on-Trent, Walsall, Wolverhampton, Rowley Regis M.B., and Stafford M.B.); and 5 cases each in Lincoln (Lindsey), Middlesex, Worcester, Yorks, North Riding, and Monmouth. In Scotland notifications rose from 35 to 43; these were recorded in the counties of Aberdeen, Ayr, Dumbarton, and Fife, 2 each; in Angus, East Lothian, Midlothian, Perth and Kinross, Renfrew, Clackmannan, Dumfries, and Zetland, 1 each; and in Glasgow 15, Edinburgh 4, Aberdeen 3, Falkirk 2, and 1 each in Arbroath, Dundee, and Dunfermline.

No. 1

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended January 4, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	(b)	(c)	(d)	(e)	1940 (Corresponding Week) (a)	(b)	(c)	(d)	(e

* Notification in certain administrative areas only.

† Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

‡ Death from puerperal sepsis.

§ Includes figures for puerperal fever.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Mediscera Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Why Not Morphine for Small Babies?

DR. W. F. MOORE (Inch, Co. Wexford) writes: When I was a student I was taught that morphine ought not to be given to young children, and I notice that Dr. Leonard A. de Dombal (January 4, p. 32) in the case of young babies gives pot. brom. instead of morphine. After being in practice some years I ignored the above teaching, and found morphine a useful and safe drug, even in very young babies. I worked out a dose which I found to act quite well: for each month of the child's age I gave 1/16th of a minim of liq. morph. mur.—that is, for a child, say, 5 months old I added 5 minims of liq. morph. mur. to a 2-oz. bottle of water and gave teaspoonful doses. I gave this even to younger babies. This small dose seemed to give great relief and was quite safe.

Income Tax

Wife Living Abroad

"J. A." has a wife and child living abroad. "Owing to adverse conditions" he was not able to send his wife her remittance for 1939, but is now sending her a draft to cover her expenses for that year. He has been refused the marriage allowance for 1939–40.

*** We assume that "J. A." is not legally separated from his wife, in which case the fact that they are residing in different countries for the time being would not appear to invalidate his claim to the married man's allowance. In any case, however, the fact that he is now sending his wife a draft to cover her "support" for 1939–40 goes to show that he supported her for that year. If the local inspector declines to make the allowance we advise our correspondent to write to the Secretary, Board of Inland Revenue, Somerset House, W.C.2. The inspector's request for "a record of *personal* expenses" is quite unusual. In the absence of any statement as to the particular reason for the request, however, we cannot make further comment.

LETTERS, NOTES, ETC.

Treatment of Paronychia

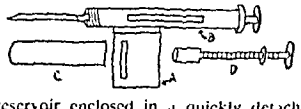
DR. H. G. LANGDALE-SMITH (Tarrington) writes: Paronychia was more prevalent than usual last autumn, and although sulphanilamide preparations applied locally had little effect I found that good results were obtained if Bier's congestive treatment was preceded by administration of sulphanilamide. Sulphanilamide is absorbed into the blood stream within half an hour of its administration by the mouth, and is distributed evenly in the circulation, reaching its maximum concentration within six hours. If Bier's treatment is applied within this period one would expect a high concentration of the drug to the affected region. I wonder if this could not be applied to war wounds infected by the streptococcal group. One well remembers the devastating effect of infection in the last war and the many methods used to mitigate it.

With regard to the usual instruction of withholding eggs, onions, and salts during administration of a sulphonamide, one wonders if it is necessary to include salts. I understood from one authority that the only contraindication to using salts was that peristalsis liberated free sulphur from the intestinal contents, and that any aperient might do the same. It seems probable that salts are not altered chemically in the small intestine, or else there would be little osmosis effect; whereas the sulphur of eggs and onions would no doubt be split up in the small bowel and would find its way through the portal system into the systemic.

Diphtheria Incidence

DR. R. M. COURTAULD (Earls Colne, Essex) writes: While thanking Dr. Anderson (January 25, p. 144) for his letter, I am bound to say that I do not find in it the explanation for which I asked. The question is: Why, when many more children than previously have been immunized against diphtheria, is there more diphtheria now than there was a year ago? In the Epidemiological Notes in the *Journal* of January 18 there are comments upon the present incidence of diphtheria, but I cannot find in them the explanation asked for. If a record were kept of the respective numbers of inoculated and uninoculated diphtheria patients admitted to isolation hospitals a practical test would be provided of the efficacy of the immunizing methods now in use.

Human Fertility



DR. ELLIA BERSTOCK (Maltby) writes: I have been interested in Dr. John Pryde's article (January 4, p. 12) and in the correspondence culminating therefrom. In matters concerning the menstrual cycle and the fertility of women during certain periods of this cycle one cannot state any dogmatic rules. Every woman is a law unto herself. I should say, from various observations I have made, that 50% of women at various times of their menstrual cycle as well as at various different times of the year are less fertile than at others. We know that is a fact with the majority of other mammals. The "safe period of Knaus" does exist, but no reliance can be put on it unless the woman has had coitus previously and did not conceive; even then it is possible that all the various adjuvants to conception taking place may not have been present—that is, love-making, desire of the two parties, etc. Often when sexual intercourse is denied, as in the case cited by Dr. R. Palmer (January 25, p. 137), it is found that when renewed after a period of continence the safe period which may have existed before in the woman is in abeyance, partly because of the repression and the intense desire of the two parties for cohabitation, and possibly because of the greater sperm strength and motility.

Medical Service in China

DR. ANDREW MORLAND, chairman of the Medical Subcommittee, Friends Ambulance Unit, writes from 135, Harley Street, London, W.1: It is hoped to send a fully equipped ambulance convoy of some fifty or sixty members of the Friends Ambulance Unit to Central China as soon as possible, and the Foreign Office has approved of the expedition. A number of doctors will be required, and it is hoped that the convoy will comprise a mobile team. Qualified men of British nationality who would like to join the convoy should apply to me.

A Repeating Syringe

MAJOR E. M. ROBERTSON FRAZER writes: Recent experiences have led me to experiment with a syringe which would be capable of carrying its own "magazine" of solution, and, by "pre-setting" the dose, could be used in the dark or for dealing with numbers of cases all requiring the same dose. Such applications would be found in the injection of morphine or in inoculations. Messrs. Abbott's Laboratories (England), Ltd., have now placed such an instrument on the market.

A is a glass reservoir enclosed in a quickly detachable metal cover fitted with a "window" and holding 50 c.cm.

B is a 2-c.cm. glass syringe enclosed in a metal barrel (with slit window).

C is a quickly detachable metal needle protector.

D is an adjustable stop to limit the travel of the plunger and thus regulate the capacity of the barrel.

The whole can be carried in the pocket and cannot be spilled. The dose may be "pre-set" from 0.1 c.cm. to 2 c.cm. as in the regulation Army syringe, but the presence of air can be detected in the window. The mechanism is simple, and the two ball-valves cannot get out of adjustment. The needle cap can be kept filled with a quantity of carbolized vaseline, the needle stylet being left *in situ*. In action, one withdrawal of the plunger fills the syringe, one "push" completes the injection, and the syringe is recharged with the next withdrawal, and so on, until the reservoir is empty. Injections are made as easily as with the standard type of syringe, and the time saved when dealing with large numbers is considerable. The whole instrument may be sterilized by washing out with alcohol or by boiling, while the needle may be changed between injections or sterilized by flame. It is suggested that such an instrument might also be of use to school and public health clinicians, or for intravenous anaesthesia.

THE EFFECT OF PERITONEAL IRRITATION ON THE ACTIVITY OF THE INTESTINE

BY

D. M. DOUGLAS, M.S., Ch.M., F.R.C.S.

Late Commonwealth Fellow in Surgery on assignment in the Mayo Foundation; First Assistant in Surgery, British Postgraduate Medical School

AND

F. C. MANN, M.D.

Director of the Institute of Experimental Medicine, the Mayo Foundation

The management of abdominal distension occurring in the course of diffuse peritonitis is still a major surgical problem. Two principal views are widely held concerning the pathogenesis of the condition, the one contending that the distension is the result of multiple adhesive obstructions in the intestine, and the other that the activity of the intestine is reflexly inhibited by reason of the peritoneal irritation. The views might reasonably be termed respectively "mechanical" and "neurogenic." These two concepts are of more than academic interest, since the mode of treatment, operative or conservative, is influenced by the view held by the individual surgeon. There are, of course, cases in which the obstructive element is quite obvious. The patient who is suffering from painful attacks of colic and in whom peristalsis is audible often even without the use of a stethoscope is evidently not suffering from inhibition of intestinal activity. But it must be confessed that such cases are less common than those in which little evidence of intestinal activity can be detected.

The purpose of this paper is to present some observations on the effect of peritoneal irritation on the activity of the intestine. It is apparent that, in order to study reflex phenomena adequately, it is necessary in some way to separate the receptor and the effector elements in the hypothetical reflex arc. In other words, if equivocal results are to be avoided the adequate stimulus must be delivered at a site remote from that in which the reflex effect is to be studied. It was by the application of this principle that Pavlov was enabled to study the various phases of gastric secretion. The pouch which bears his name was so devised that he could collect samples of gastric juice from a portion of the stomach which, while retaining its nerve supply, was completely cut off from the adequate stimulus, which was the entry of food into the remainder of the stomach.

We endeavoured to find a method whereby this principle could be applied to the study of paralytic ileus; in other words, we wished to devise a preparation which would permit of the production of diffuse peritoneal irritation without at the same time producing local peritonitis of the intestine in which the reflex effect of the peritoneal irritation was to be expected. We believed that any effect which might be observed could, if time relations were compatible, be reasonably regarded as reflex in character, and would be a suitable phenomenon for the study of mediation of inhibition in the intestine in response to peritoneal irritation.

A complete review of the literature which has accumulated, particularly on the clinical side of this field, would be outside the scope of a communication of this type. Accordingly, it is proposed to refer only to the more important papers in the experimental field on which the neurogenic concept of paralytic ileus is based. Van Braam Houckgeest in 1872 made the observation that abdominal section and exposure of the intestines had an inhibitory effect on intestinal activity. It was not till 1899 that Bayliss and Starling found that this inhibition could be overcome after a short latent period by section of the splanchnic nerves. Cannon and Murphy (1907) showed that a similar type of intestinal inhibition could be caused in cats by local trauma to the intestines or reflexly by trauma to the testes, and, similarly, that this inhibition could be prevented by previous splanchnicotomy. In the rabbit, Melzer and Auer (1907) and Hotz (1909) demonstrated that certain inhibitory intestinal reflexes could be prevented by destruction of the cord to the third dorsal segment or by splanchnic section. Arai (1921) observed intestinal inhibition in cats after the intraperitoneal injection of irritant solutions, and King (1924) demonstrated similar inhibition in dogs from stimulation of bladder, rectum, peritoneum, and various skin areas. Olivecrona (1926–7) concluded that, in the cat, local reflexes mediated by way of the coeliac ganglia were capable of causing intestinal inhibition. Markowitz and Campbell (1927) and Ochsner, Gage, and Cutting (1928) showed that the inhibition of peritonitis in dogs could be prevented by spinal or splanchnic anaesthesia. Alvarez and Hosoi (1929) suggested that in the ileus of peritonitis a flattening of the normal gradient of forces occurred. Demel (1926) reported that atony of the bowel of the dog could be produced by retroperitoneal injection of blood. The recent work of Youmans, Herrin, and Meek (1938) suggests that distension of one part of the intestine causes inhibition of other parts.

Experimental Methods

Three main problems confronted us at the outset of this study. The first has already been referred to—namely, the devising of a suitable preparation. The second was the difficulty of finding a standard by which

inhibition of intestinal activity could be judged; the third was the choice of a method for the production of peritoneal irritation.

The first problem was solved by means of the preparation described by Biebl (1930) for the collection of samples of intestinal contents and used later by Castleton (1934) and Wangensteen (1937). It consists of an exteriorized loop of intestine, in continuity, with extrinsic nerve and blood supply intact, enclosed in a bipedicled tube of skin exactly similar to that used in plastic surgery (Fig. 1). The parietal and visceral peritoneum at the

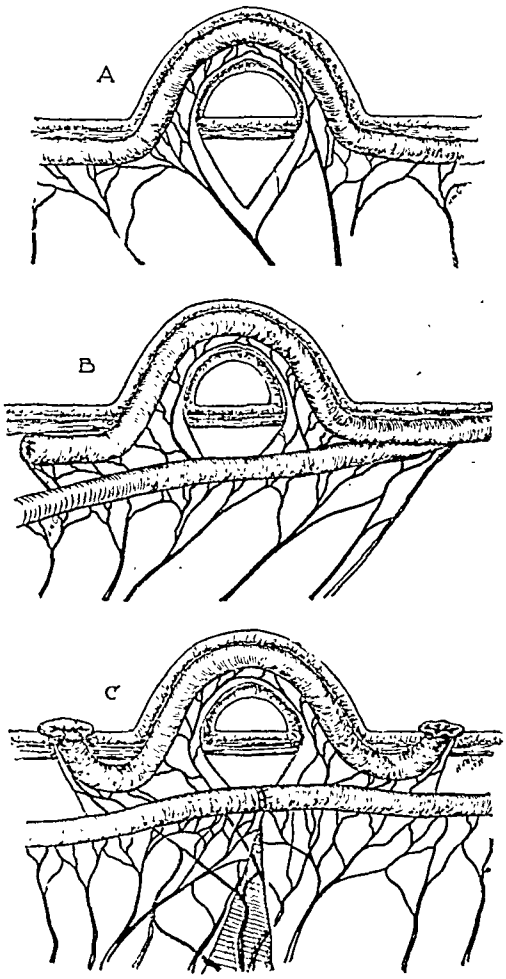

FIG. 1.—Types of exteriorized loops of intestine enclosed in bipedicled skin tubes. A: In continuity as used in the present study. B: Short-circuited. C: Isolated—analogous to the Thiry-Vella loop.

exit and entrance of the loop from the peritoneal cavity become firmly adherent to each other and so effectively seal off the whole loop from the peritoneal cavity, while the lumen of the bowel, exactly comparable to a colostomy loop before opening, remains patent. By virtue of the exteriorized position of the loop and of the effective sealing off of its visceral peritoneal surface from the general peritoneal cavity it is possible to set up an inflammatory process within the latter without in any way directly affecting the former. The operative procedure involved in the preparation of these loops is simple, the operative mortality is low, and the animals can be observed in good health for many months. The advantages and disadvantages of the preparation have been discussed in a previous communication (Douglas and Mann, 1939). For the present purpose the advantages appeared to outweigh the disadvantages.

As to the second problem, it requires only a cursory glance at the literature to realize that no accurate concept exists as to what constitutes inhibition of intestinal activity. One of the main causes of this confusion appears to lie in the fact that a great diversity of methods have been used to study intestinal activity. Thus workers with an intraluminal technique naturally tend to regard inhibition in terms of tonus; workers using enterographic methods lay stress on diminution of amplitude and rate of contraction; and those using radiographic technique speak in terms of the progress of food residues. Since coincident with a fall in tonus there may be an increase in the amplitude and rate of contraction, and vice versa, it is easy to see how conflicting results may arise. In order to avoid confusion of this type the term "inhibition of intestinal activity" in the present study has been taken to mean absolute quiescence of the intestine—that is, where neither by the recording technique nor visually could any movement whatever be observed. Inhibition was considered to have come to an end when the first contraction, however small, reappeared. Thus it was possible with some degree of accuracy to measure quantitatively the duration of inhibition.

In the production of peritoneal irritation the intraperitoneal injection of irritant solutions was adopted for the following reasons: (1) the technique of intraperitoneal injection is a well-standardized procedure, simple of execution, requiring no anaesthesia, and without detrimental effect on the animal; (2) the method has been used extensively in studies of this nature, and the injection of a known quantity of irritant solution is in some respects quantitative and is easily controlled by the injection of bland non-irritant solutions; (3) the injection is in the nature of a sudden peritoneal insult analogous to the perforation of a hollow viscus, and is therefore well suited to the present study; (4) finally, recovery from the small quantities of irritant solution used was rapid and uneventful.

In view of the species differences which are said to exist with respect to intestinal activity it was thought wise to study two types of animals. The rabbit and the dog were therefore used, and, in order to have data on the small and large intestine, loops were prepared from the caecum of the rabbit and the ileum of the dog. Records of intestinal activity were taken in the rabbit by an enterographic method and in the dog by a double-tambour air-displacement system (Fig. 2).

Procedure of the Experiments.—The same technique was used throughout. The animal was fed before the experiment to ensure maximum activity of the intestine. It was then placed on an observation table, upon which it had been previously trained to lie. A 20-gauge needle was inserted into the peritoneal cavity and a length of rubber tubing attached to it, secured to the abdominal wall by adhesive tape. A control tracing of intestinal activity was then taken for a period of fifteen minutes. A measured quantity of Ringer-Locke's solution at 39° C. was now injected into the peritoneal cavity and the tracing was continued for thirty minutes. A similar quantity of irritant solution at 39° C. was then injected and the tracing was continued for a period of two to three hours. Since the tracing was taken continuously throughout the whole of the experiment it was possible to record the reaction of the exteriorized loop of intestine to the intraperitoneal irritative process. In no instance did the injection of Ringer-Locke solution have any effect on the intestinal activity.

Preparations.—Experiments were carried out in the following preparations: (1) the normal animal; (2) the animal with bilateral splanchnic section; (3) the animal with bilateral vagal section; (4) the animal with unilateral splanchnic section; (5) the animal with bilateral adrenal-

ectomy. The splanchnic nerves were severed through a lumbar approach, the vagi through a thoracic approach immediately above the oesophageal hiatus in the diaphragm. No experiments were carried out after the nerve sections until a period of at least three weeks had elapsed. This was to allow of degenerative processes in the synaptic connexions which these nerves make in the myenteric plexus. The adrenalectomized animal was given a daily maintenance dose of adrenal cortical extract and a diet

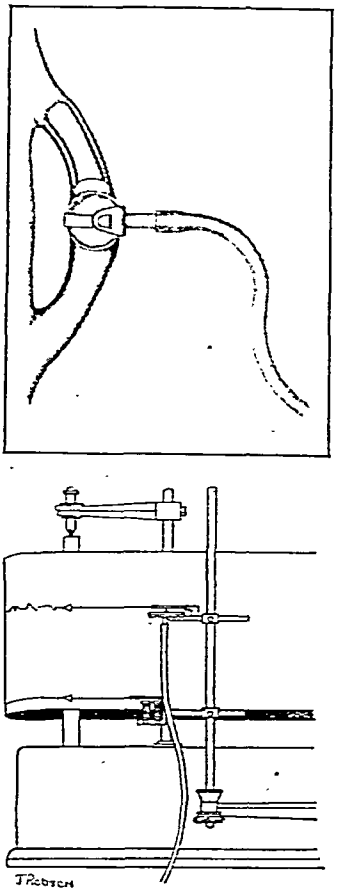

FIG. 2.—Simple air-displacement system. The receiving tambour is attached to the intestinal loop by an inelastic aluminium clip.

low in potassium. Both the animals with nerve sections and the adrenalectomized animal maintained good health and, so far as could be judged by bowel habits and tracings of intestinal activity, showed no deviation from the normal in respect of the alimentary canal. This is in accordance with the findings of other observers.

Results

THE RABBIT

The Normal Rabbit.—Eleven experiments were carried out in the normal rabbit. In all of them immediate and prolonged inhibition of the movements of the loop was observed in response to the intraperitoneal injection of a small amount of irritant solution (Table I). The nature of the irritant solution did not appear to be of importance, since sodium ricinoleate solution, turpentine emulsion, and Lugol's iodine solution produced a similar result.

TABLE I.—*Effect of Intraperitoneal Injection of Irritant Solution on the Activity of the Intestine of the Rabbit*

Animal	Irritant	Quantity in c.cm.	Dilution	Inhibition	Duration in Mins.
		Normal Rabbit:			
1	Sodium ricinoleate	5	1 : 50	+	120
2	Lugol's solution	3	1 : 10	+	35
3	Turpentine	2	1 : 20	+	103
4	Lugol's solution	2	1 : 10	+	30
5	"	2	1 : 10	+	43

14	"	3	1 : 10	"	
15	"	3	1 : 10	"	
16	"	3	1 : 10	"	

The Splanchnicotomized Rabbit.—Five experiments were performed in the rabbits which had had both splanchnic nerves previously sectioned. Although these animals showed a similar systemic response to the injection of the irritant, in no case was inhibition of movements of the extraperitoneal loop observed (Table I).

THE DOG

The Normal Dog.—Five experiments were carried out in the normal dog. As in the normal rabbit, immediate and prolonged inhibition of activity in the extraperitoneal loop was observed (Table II and Fig. 3).

TABLE II.—*Effect of Intraperitoneal Injection of Irritant Solution (Lugol's Iodine) on the Activity of the Intestine of the Dog*

Animal	Quantity in c.cm.	Dilution	Inhibition	Duration in Mins.
		Normal Dog:		
1	4	1 : 2	−	75
2	3	Undiluted	−	240
3	4	1 : 3	+	54
4	4	1 : 3	−	53
5	4	1 : 3	−	94
		Splanchnicotomized Dog:		
6	4	1 : 2	+	1
7	4	1 : 2	Nil	
8	4	1 : 2	+	0·25 (15 sec.)
		Vagotomized Dog:		
9	2	1 : 3	+	75
9	3	1 : 2	+	64
		Unilaterally Splanchnicotomized Dog:		
10	4	1 : 4	+	81
10	3	1 : 4	+	72
		Adrenalectomized Dog:		
11	4	1 : 2	+	32
11	4	1 : 2	+	32
11	4	1 : 2	+	24

The Splanchnicotomized Dog.—Three experiments were carried out in the animals with bilateral splanchnic section (Table II). In one experiment no inhibition was noted in response to the intraperitoneal injection of the irritant solution; in the two others transitory delayed inhibition was noted (Fig. 3). The same experimental manœuvre produced in the normal dog immediate and prolonged inhibition.

The Vagotomized Dog.—Two experiments were carried out in the vagotomized dog. Prolonged inhibition of intestinal activity was observed in both (Table II). The reaction was similar to that seen in the normal dog (Fig. 3).

The Unilaterally Splanchnicotomized Dog.—Two experiments were carried out in the unilaterally splanchnicotomized dog. As in the normal dog and the vagotomized dog, prolonged inhibition of activity in the extraperitoneal loop occurred (Table II and Fig. 4).

The Adrenalectomized Dog.—Three experiments were carried out in the dog which had had both adrenal glands removed three weeks before. In all three experiments a result similar to that seen in the normal dog was noted—namely, immediate and prolonged inhibition of intestinal activity (Table II and Fig. 4).

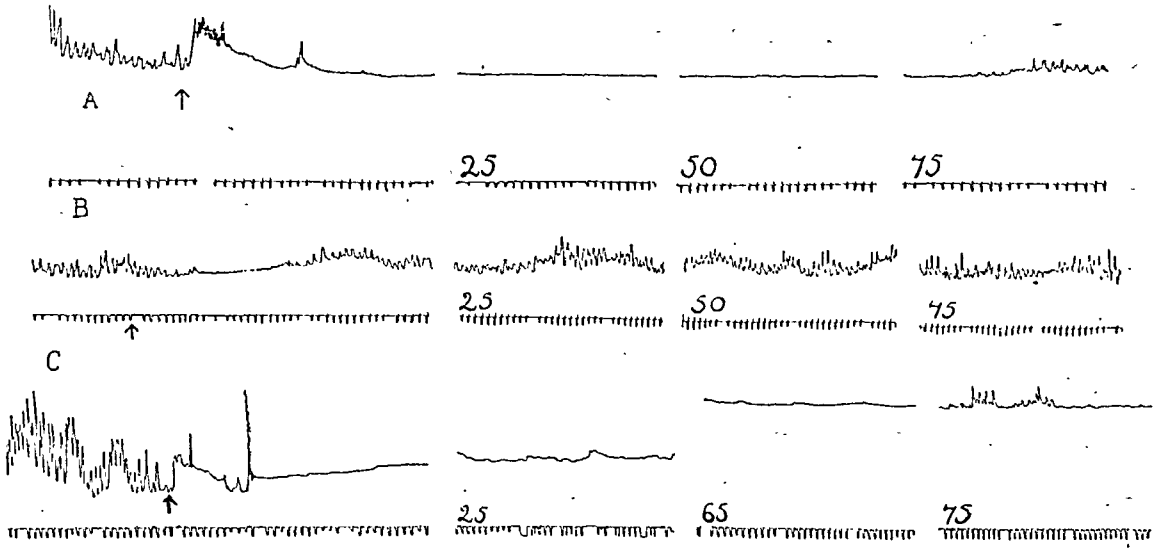

FIG. 3.—Effect of intraperitoneal injection of irritant solution on the activity of the intestine. At arrow, standard quantity of solution injected into peritoneal cavity. Large numbers indicate minutes. Time in 5-second intervals. A: Normal dog. B: Dog with bilateral splanchnic section. C: Dog with bilateral vagal section.

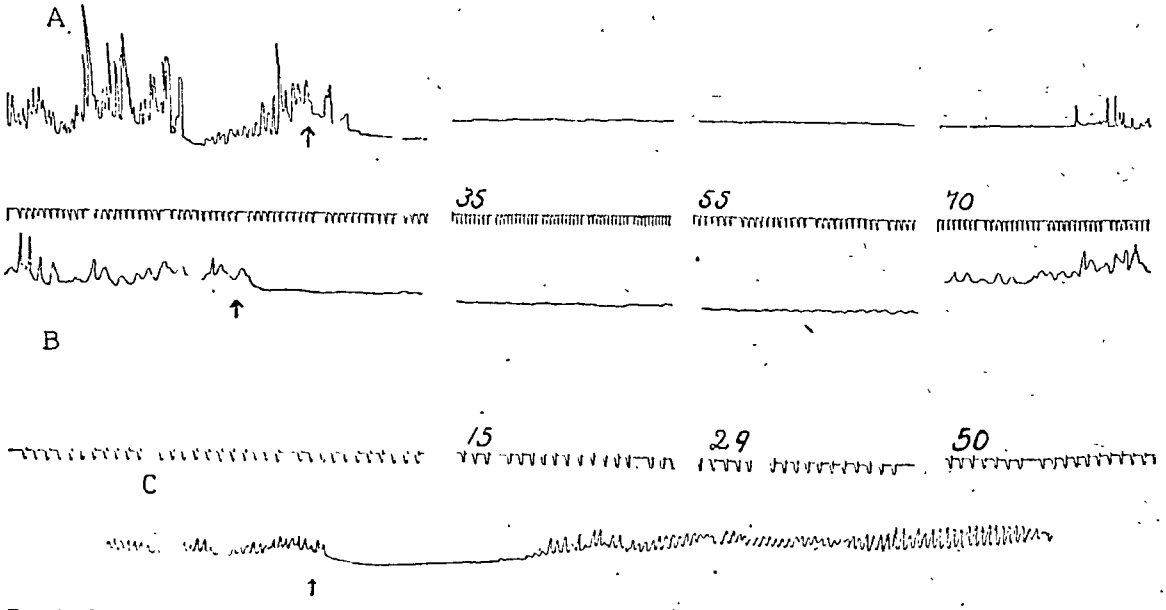

FIG. 4.—Effect of intraperitoneal injection of irritant solution on the activity of the intestine. At arrow, standard quantity of solution injected into the peritoneal cavity. Large numbers indicate minutes. Time in 5-second intervals. A: Dog with unilateral splanchnic section. B: Dog with bilateral adrenalectomy. C: Effect of intravenous injection of 0.25 c.cm. of adrenaline on the activity of the intestine.

Comment

The arrest of intestinal activity consequent on the injection of irritant solutions into the peritoneal cavity noted in this study is in all likelihood true reflex inhibition, since no drugs were used, there was no handling of the bowel, and no foreign bodies were introduced into the bowel. Moreover, the arrest occurred irrespective of the nature of the irritant solution, and no arrest was observed when a non-irritating solution such as Ringer-Locke was used. A direct effect on the bowel could be excluded because of the extraperitoneal situation of the bowel under study.

The experiments after bilateral vagal section indicate that the vagus nerves play little part in mediating the inhibition either as afferents or efferents, since the inhibition is similar to that seen in the normal animal. Similarly, the observations after unilateral splanchnic section indicate that the absence of the splanchnic nerves on one side alone does not prevent the mediation of the inhibition. The experiments after bilateral splanchnicotomy, on the other hand, indicate that the inhibitory process is mediated through the splanchnic nerves, since either no inhibition occurred or, as in two experiments, it was momentary.

It is well known that adrenaline causes inhibition of intestinal activity (Fig. 4). It was with this consideration

in mind that experiments were carried out in the adrenalectomized animal. The inhibition seen in the adrenalectomized animal was similar to that in the normal animal, though of shorter duration. It may be that part of the inhibition observed in the normal animal is mediated by the adrenal medullary principle and that the transient inhibition seen in two experiments in the splanchnicotomized animal was similarly effected.

Olivecrona (1926-7) attempted to draw a distinction between rhythmic and peristaltic activity in respect to their response to peritoneal irritation, indicating that the latter type is very readily inhibited whilst the former persists. An analysis of this type is extremely difficult under reasonably normal experimental conditions, and it was therefore purposely avoided in this study. Since, however, we took absolute quiescence as the criterion of intestinal inhibition the problem did not arise.

We are well aware of the danger of applying experimental observations to clinical problems. Nevertheless it seems of considerable interest that an irritative process within the peritoneal cavity is capable of bringing about a prolonged arrest of activity in intestine which is entirely remote from the peritonitis. We take this as reasonable evidence that the neurogenic or reflex concept of distension in diffuse peritonitis is not the chimera which many authors suggest, particularly when so many cases recover without operative intervention. To enter into a discussion on the virtues of the various lines of treatment would be outside the scope of a paper of this kind, but it is permissible to suggest that enterostomy or enteroanastomosis is not likely to meet with success in cases in which the activity of the intestine is inhibited. We would therefore plead that, in the absence of obvious intestinal activity, there are good grounds for the adoption of conservative measures in the treatment of the distension of peritonitis. Measures calculated to overcome splanchnic inhibition such as splanchnic block or the use of acetylcholine protectives such as prostigmin would appear to be rational therapy.

Summary

1. Extraperitoneal loops of bowel in continuity were prepared in the rabbit and dog. A loop of the caecum was chosen in the former, of the small bowel in the latter.

2. Peritoneal irritation produced by intraperitoneal injections of a standard irritant solution was constantly associated with prolonged arrest of movements in the extraperitoneal loop in the trained animal.

3. The arrest of intestinal movements occurred after degenerative section of both vagus nerves, of one splanchnic nerve, and after bilateral adrenalectomy.

4. After degenerative section of both splanchnic nerves the arrest did not occur or was only temporary.

5. The arrest is in the nature of reflex inhibition, because by reason of the extraperitoneal situation of the loop of bowel the stimulus is delivered to afferents other than those in the loop.

6. The anatomical pathway of the reflex arc is not fully determined.

(*a*) The receptor endings are in the peritoneal cavity, but whether in parietal or visceral peritoneum or both is unknown. Cannon and Alvarez have each found evidence for visceral receptors; Hotz and King have found evidence for parietal receptors.

(*b*) The afferent limb of the arc is similarly unknown. Cerebrospinal afferents from the parietal peritoneum are almost certainly involved.

(*c*) The connector element is made up of the preganglionic neurones of the thoracic outflow which constitute the splanchnic nerves.

(*d*) The efferent limb of the arc is made up of the postganglionic sympathetic neurones issuing from the coeliac plexus.

(*e*) The effector endings are in the extraperitoneal loop of the bowel.

7. In the normal animal it is possible that part of the duration of the inhibition may be mediated by adrenaline, and that in the animal with bilateral degenerative section of the major splanchnic nerves the transitory inhibition noted was similarly mediated.

The findings are taken to indicate that prolonged intestinal inhibition may result reflexly from irritation of the peritoneum, that the inhibition is mediated by the splanchnic nerves, and that there is a sound physiological basis for the neurogenic concept of paralytic ileus.

It is a great pleasure to make acknowledgment to the Commonwealth Fund, New York, and to the Mayo Foundation, Rochester, Minnesota, for their kindness and for the facilities for carrying out this work.

TREATMENT OF OPEN WOUNDS BY THE SULPHANILAMIDE PACK

BY

A. C. KING, F.R.C.S.

Major, R.A.M.C.

This is an account of a method of treatment for open wounds employed by the surgical specialist to a casualty clearing station during the fighting in France and Belgium which ended with the evacuation of Dunkirk. If the reader finds the article lacking in specific detail he is asked to remember that all the writer's records, together with the rest of his personal belongings, were lost at Dunkirk, and that the paper is not meant to be an exhaustive survey from which conclusions may be drawn, but rather one surgeon's experience in a limited number of cases.

The method used in this treatment of open wounds was to pack them with powdered sulphanilamide. Sulphapyridine (M & B 693) was never used. At no time during the treatment was sulphanilamide given by mouth, nor was it given to controls treated with a flavine pack. Any effect was exerted by the presence of sulphanilamide locally in the wounds. The anaesthetic employed was sodium pentothal, combined with gas-and-oxygen.

Technique

Pre-operative treatment was as in ordinary surgical procedure. The skin edges of the wound were then excised and the depths of the wound examined. After the extent of the wound had been ascertained the skin opening was enlarged and the whole area laid open to allow for drainage. As a general rule the area of damaged muscle was very much greater than the aperture which led to it through the skin. This was particularly the case in wounds from trench-mortar fragments.

All muscle fragments, all discoloured muscle, and all muscle which although apparently healthy in colour did not respond to stimulation by contraction or twitching were removed. Whenever doubt existed as to the viability of the muscle it was left and no extensive excision was undertaken. The wound was made shelving so far as possible during this excision of muscle. Absolute haemostasis was then secured, all bleeding points being ligatured and all the oozing checked by the introduction of hydrogen peroxide into the wound. Powdered sulphanilamide was then placed in the cavity. It is of the greatest importance to introduce it into every corner, pocket, etc., of the wound. Failure to observe this precaution is, in my opinion, responsible for partial failures and doubtful results. When treating the first few cases sulphanilamide was poured into the wounds. This was found to be unsatisfactory, as some corners were left untouched. A large Volkmann spoon was then used to introduce the powder. This was also found to be unsatisfactory, although better than merely pouring it in. When in contact with the serous exudate on the surface of cut muscles the powder becomes a paste and adheres to the muscle, so that most of it is lost from the spoon by the time the deeper recesses are reached. Moreover, the remainder tends to adhere to the spoon, will not pour, and is difficult to get into the deeper recesses. Finally, half a tablet of sulphanilamide was held in the jaws of a pair of Spencer Wells forceps, and introduced into the depths of the wound at the required site. The half-tablet was then crushed by the forceps, the forceps withdrawn, and the crushed half-tablet left in the required position. This procedure was repeated in any part of the wound that seemed unlikely to be reached by the mere pouring in of powder. After all recesses had been filled in, the main cavity was packed with powdered sulphanilamide, 20 grammes being introduced. Insufflation might be still more simple than the above method. I have not tried it, as the necessary equipment was not available.

After the wound had been filled in with sulphanilamide it was left open, no attempt at suture being made. The open wound was covered with gauze smeared with sterile vaseline, and over this was placed elastoplast or zinc oxide strapping, with the intention of closing the wound and of drawing the skin edges together so far as was possible. Wool was superimposed and the whole bandaged. If the wound involved a compound fracture the appropriate extension was applied.

During the ensuing twenty-four hours there was always some blood-stained serous ooze which soaked through the wool and bandage. This did not necessitate removing the bandage, but a fresh layer of wool was applied, this being covered with a fresh bandage. This procedure was repeated if necessary. The wound was not interfered with. No further treatment was undertaken until the fifth day after operation, when the wound was dressed and delayed primary suture was undertaken. By this time all the sulphanilamide had dissolved, and the wound was clean, had begun to granulate, and was suitable for suture.

The total number of cases treated by this method amounted to between 40 and 50. They fell into two groups—those treated previous to May 10, 1940, and those treated between May 10 and May 29. The former group comprises cases arising when an army is in the field and not in action with the enemy, and consists of compound fractures and penetrating wounds arising from road accidents, football accidents, etc.—exactly similar to cases met with in ordinary civil practice. The second group comprises cases resulting from enemy action —gunshot wounds, wounds from bomb splinters, trench-mortar splinters, etc.—cases similar to those met with in this country after enemy air raids. All the cases treated were wounds of limbs: no attempt was made to treat by this method abdominal, chest, or head wounds.

Group I: Cases Treated Before May 10, 1940

Cases treated in this group show a further difference from the cases treated subsequently. A culture was taken from the depths of the wound before any treatment was instituted, and a further culture was taken five days later when the wound was first dressed. Working in a C.C.S. I did not see the results of my treatment, since the cases had been evacuated to the base by the fifth day; but by courtesy of Colonel Leonard Colebrook, R.A.M.C., I was supplied with details of the progress of my cases, and could thus form an estimate of the value of this method of treatment.

After May 10 there was neither time nor opportunity for the procedure carried out previously. Cases were treated with the sulphanilamide pack, and owing to the delay in evacuation it was often possible to observe them for five days after treatment. A further difference between the two groups must be emphasized. Before May 10 cases were admitted and treated shortly after their injury, the usual interval being six hours or less, except in those with severe shock, which it was necessary to treat before attempting anything else. After May 10 cases were admitted to the C.C.S. days, not hours, after being wounded. Forty-eight hours' interval was normal; seventy-two hours' interval was frequent. Consequently infection was established before treatment was instituted; so that while it may be said that this treatment before May 10 was prophylactic, after May 10 it was definitely curative in action.

Group I cases comprised compound fractures of the long bones, penetrating wounds of joints, deep lacerations of the limbs, and two cases of stab wounds. Their total number was 15. They were all treated in the manner described under the heading "Technique," except that in the early cases not enough care was taken to ensure that the powder reached every recess in the wound. Certain of these cases have remained in the memory. They are given here, not necessarily in chronological order.

Case 1. A Motor-cycle Accident.—The left foot had been nearly avulsed. The patient was suffering from a compound comminuted fracture of the lower end of the left tibia, the capsular ligament of the left ankle-joint had been ruptured, and the cavity of the joint was exposed. The patient was admitted about six hours after the injury had been inflicted. The wound was excised and sulphanilamide introduced. A culture was obtained before treatment. This failed to grow organisms. The joint was fixed in the best position for ankylosis, on a back splint, and forty-eight hours later the patient was transferred to the base. After five days the wound was dressed and found to be completely sterile. It was sutured, and so far as my information extends the patient made an uninterrupted recovery.

Case 2. A Motor-cycle Accident.—There was a penetrating wound on the inner side of the right knee-joint. The joint surfaces were exposed, and much debris was present in the wound. The synovia was sutured with interrupted suture. The remainder of the wound was excised and packed with sulphanilamide. A culture was negative. The joint was fixed in the best position for ankylosis. After five days the wound was sterile. Delayed primary suture was performed, and the patient made an uninterrupted recovery.

Case 3. Deep Laceration of Anterior Aspect of Thigh.—Preliminary culture was sterile. Sulphanilamide was poured into the wound. This was an early case. The report from the base was to the effect that on dressing the wound five days later most of it appeared to be healthy. However, a bead of pus was noticed in one corner of the wound. Cultures of this bead revealed the presence of *Streptococcus haemolyticus.*

Cultures from the remainder of the wound were sterile. The patient suffered from no general disturbance, and his temperature and pulse were normal.

In no case was there any rise in the temperature or the pulse rate during the first forty-eight hours after treatment in patients treated by this method. They, without exception, described themselves as feeling very well. They slept well and morphine was not required. There was no cyanosis, and no signs were observed of overdosing with the sulphanilamide. Sulphanilamide is not a very soluble substance, and the powder is dissolved gradually and gives a steady supply of the drug. Other information about these cases is not available. Two cases revealed the presence of *Streptococcus faecalis* after five days, and in these I am doubtful of the efficacy of my technique.

Group II: Cases Treated After May 10, 1940

These comprise cases which were for the most part heavily infected before treatment was started. These patients had been wounded days before they arrived for treatment. No cultures were taken, and no attempt was made to diagnose the individual infection, but a rough classification was made into wounds infected by gas-producing organisms and wounds not so infected. The latter included both staphylococcal and streptococcal infections. The former included presumably infections by all forms of gas-producing organisms. These were diagnosed by the smell issuing from the wounds, the crepitus in the surrounding tissues, the presence of frothy discharge in the wound, the presence of blackened muscle bellies adjacent to apparently normal muscle, and the general condition of the patient: running pulse, brown furred tongue, intense toxaemia, and sometimes delirium. As the arrangements for evacuation were not working smoothly we were compelled to keep our wounded for some time until new arrangements could be improvised. This enabled us to watch the progress of each case for a period longer than was possible during the time that routine evacuation was taking place.

In this period, also, circumstances compelled us to treat many wounds with a flavine pack, since our supplies of sulphanilamide were limited. Thus an involuntary system of controls was instituted, and we were able to watch the progress of a series of wounds treated with sulphanilamide and to compare them with a series treated with flavine. As a general rule we reserved our sulphanilamide for the more serious, the more heavily infected, and the more extensively lacerated wounds. Flavine was used for gunshot wounds, for wounds that did not seem seriously infected, and for cases in which, whatever—within limits—the condition of the wound, the patient's general condition, the absence of toxaemia, etc., showed that he was resisting well without outside aid. All wounds in which crepitus extended from the wound and in which frothy discharge showed infection with gas-forming organisms were treated with sulphanilamide so far as our means allowed.

The following two cases seem worthy of mention:

Case 4.—Described to me by the surgical specialist of another C.C.S. Case admitted three days after wounds from bomb splinters. Wound of lower portion of left thigh involving compound fracture of left femur, and a further wound of the upper portion of the left leg involving the antero-external muscular part of the leg. There was also a compound fracture of the left tibia in its upper end and gas gangrene in both wounds. Wounds excised: gangrenous muscular bellies removed. Twenty grammes of sulphanilamide packed into each wound. Within twenty-four hours patient's general condition greatly improved. Pulse below 100; temperature, which had been subnormal, normal. This improvement was maintained. Two and a half days after the pack was introduced the patient complained of pain in the lower wound. The dressings were removed: no sulphanilamide powder remained; all had been dissolved. The wound appeared clean. A gauze pack was inserted. Subsequently the patient was encountered in England with his left leg amputated. He said that the lower wound had bled several times and was discharging pus. His left popliteal artery had been ligatured through the upper wound. This intervention had lighted up the gangrene infection and had necessitated amputation of the leg.

Case 5.—Wound of upper part of right thigh. Gas-gangrene crepitus extending over the anterior abdominal wall as far as the umbilicus. Excision and sulphanilamide pack. Complete recovery.

In most cases the early results were notable: within twenty-four hours after the treatment the general condition of the patient was much improved; toxaemia was greatly if not completely reduced, the pulse rate was down to normal, and the patient suffered from no pains and was alert, taking an interest in what was going on around. This improvement lasted for the whole time these patients were under our care. No patient who had received this treatment died while he was in the C.C.S.: this in spite of the fact that the wounds were heavily infected before admission. The same cannot be said for the cases treated with a flavine pack. In these cases toxaemia, a rapid pulse, and general asthenia persisted as a marked feature, and several patients who received no more than a flavine pack died whilst under our care. I am ignorant of the later results of this treatment, and indeed it is possible that these will not be as good as the early indications promised. Nevertheless, for the surgical specialist in a C.C.S. here is a treatment which appears to control infection in wounds at least long enough to get the patients back to a base hospital under normal conditions of evacuation, and this in itself is a great advance. It is possible that the work of the surgical specialist to a C.C.S. will in future resolve itself into securing haemostasis and packing with sulphanilamide in wounds of the limbs, if not of the abdomen, chest, and head.

Mode of Action

The mode of action would appear to be both general and local. Sulphanilamide has a general effect when injected subcutaneously, since cases of cerebrospinal meningitis in which persistent vomiting has prevented the oral administration of sulphanilamide have responded to the drug when injected subcutaneously; on the other hand, the necessity of applying the powder to every part of the wound points to some local action over and above the general action already noted. It may be that the gradual dissolving of the powder produces a local concentration which has a more powerful effect. The fact that large quantities of the drug have been used in the pack without signs of overdosing would seem to show that some local action takes place and that all the powder introduced does not get into the general circulation. These considerations raise the point as to whether it is necessary, in cases of multiple wounds, to pack each wound with sulphanilamide. If the action is solely a general one it should suffice to pack one wound only, or to insert the powder at a convenient site away from any wound. If there is a local effect superimposed on the general effect it will be necessary to pack each wound separately.

Summary

A number of wounded patients have been treated by packing the wounds with sulphanilamide powder. The technique of this method is described.

A number of cases are recorded, with the early results of the treatment, and the mode of action is discussed.

It is claimed that this treatment will at least save labour and time in casualty clearing stations by controlling infection until the patient arrives at a base hospital.

PARESIS FOLLOWING HERPES ZOSTER

A REPORT OF TWO CASES

BY

A. BARHAM CARTER, M.D., M.R.C.P., D.P.M.

Physician to the Central Middlesex County Hospital; late Assistant Medical Officer, Shenley Hospital

AND

JOHN B. W. DUNLOP, M.B., M.R.C.P.

Assistant Medical Officer, Central Middlesex County Hospital

Herpes zoster is usually a benign type of infection mainly affecting the sensory part of the nervous system. Motor symptoms occur infrequently, although both upper and lower motor neurone palsies following typical zoster have been recorded. Upper motor neurone lesions were described by Besta and Vercelli (quoted by Rocchi, 1938), Bruce (1907), and Worster-Drought and McMenemey (1933). In each of these cases there seemed no other explanation for the pyramidal lesions, although Alajouanine and Griffith (1931) recorded an enlightening case in which herpes zoster followed by upper motor neurone paresis of the right leg occurred in a girl aged 17 who six years later developed typical disseminated sclerosis. Among the lower motor neurone palsies the one most often encountered is facial paralysis and occasional deafness complicating geniculate zoster. Examples of this syndrome were described by Ramsay Hunt (1907), and it is now known by his name. The next most frequently reported palsy appears to be oculomotor paresis complicating trigeminal zoster. Cases of this type have been described by Essen-Möller (1936), Federici (1937), Carmody (1937), and others.

Brachial and abdominal palsies are more uncommon: Kinnier Wilson (1940) describes a zoster of C4 segment with weakness of the deltoid and biceps (C5). He also mentioned that in any given segment concerned "either all or a few or only one muscle may be affected." Taylor (1895) recorded a case of right abdominal zoster with paralysis of the recti and obliques, and Rocchi (1938) a case of zoster affecting segments D12 and L1 on the left side with weakness of the corresponding obliques, which showed a partial reaction of degeneration. Similar cases have been described by Bloedorn and Roberts, Worster-Drought, Taylor and Chairon (quoted by Kinnier Wilson, 1940).

Lower motor neurone paralysis complicating lumbar or sacral zoster seems a rare condition. Hardy (1876) and Cornil (1930) each described one case—the former zoster of the sciatic nerve with paresis of the calf muscles, the latter zoster of the thigh with atrophy of the quadriceps and loss of the knee-jerk. Davidsohn and Oppenheim (quoted by Rocchi, 1938) observed in a sacral zoster transitory motor disturbances of the bladder and rectum.

Two personal cases of lumbar zoster, very similar in distribution and course, are described here, both complicated by lower motor neurone paresis involving the affected segments.

Case I

A widow aged 73 was admitted to the Central Middlesex Hospital on January 15, 1940. For several years she had had epigastric pain of a typical peptic ulcer pattern. Apart from this she had been well until an attack of shingles in the right leg two months previously. Since then she had been shaky, and complained of neuralgia in and weakness of this leg, which tended to give way on walking.

On examination the patient was found to be, for her age, a very well preserved woman with a slight tremor of the lips, tongue, and arms. The scars of a recent herpes zoster were present on the inner side of the right thigh and on the front of the leg in the distribution of the third and fourth lumbar roots. Cutaneous sensation to pin-prick and cotton-wool was slightly diminished over this area; elsewhere it was normal. The right quadriceps was slightly wasted and its power and that of the abductors of the thigh diminished. All the tendon reflexes were brisk, with the exception of the right knee-jerk, which was absent. The plantar reflexes were flexor and the abdominals were absent. The arms, the cranial nerves, and the fundi oculi were normal. The peripheral arteries were hardened, but the heart and lungs were normal; blood pressure was 150/90, and the urine was normal. The occult blood reactions in the faeces were positive on two out of three examinations, and a barium meal showed evidence of a simple pyloric ulcer. A fractional test meal gave a normal result.

The cerebrospinal fluid on January 20 was under normal pressure and was clear and colourless. There were 21 cells per c.mm. present—1 polymorphonuclear leucocyte and 20 lymphocytes. The total protein was 0.035% and the Lange curve 0001221000. The Wassermann reaction was negative. On February 1 the fluid contained only 14 cells per c.mm.—1 polymorph and 13 lymphocytes. A radiograph of the spine showed osteo-arthritis and some osteoporosis of the thoracic and lumbar vertebrae.

The patient was given a course of faradism and exercises to the affected muscles. A gradual improvement in power took place, and before her discharge on February 21 the right knee-jerk was noted as just present; the neuralgia was less severe than on admission. In addition she had been put on to a peptic ulcer regime with marked benefit.

She has been seen at monthly intervals since, and the cerebrospinal fluid was re-examined on April 22 and was found to contain only 1 lymphocyte per c.mm. The protein was 0.035% and the Lange curve negative. The slow improvement in power continued, and the knee-jerk was gradually increasing in briskness. When last seen on July 20, nine months after the onset of the eruption, she was looking extremely well. She had lost her dyspeptic symptoms and had gained 10 lb. The neuralgia was occurring occasionally at night only and had diminished in intensity. The right leg now appeared to her to be as strong as the left, but on examination slight weakness of the quadriceps remained and the right knee-jerk was not quite as brisk as the left.

Case II

A married woman aged 53 was admitted to Shenley Hospital on April 3, 1938, with a severe depressive reaction state and suicidal tendencies. She slowly improved mentally and was occupying herself fairly well when on September 17 she complained of severe stabbing pain in the front of the right thigh. Next day she had a temperature of 99.8° and developed a typical herpetic eruption on the front of the thigh, which spread to the inner side of the right leg the following day. The lesions approximated to the distribution of L3 and L4 spinal segments. On this day—September 19—lumbar puncture was performed, and clear fluid under normal pressure was obtained. This contained 38 lymphocytes per c.mm. and 0.05% of protein. Four days later her temperature had settled, and she complained that she could not lift her right leg from the bed. The herpetic eruption had begun to heal, although pain was persistent: some analgesia was found between the drying vesicles. Wasting of the quadriceps was observed (half an inch), with almost complete loss of power; the adductors were normal; no fibrillation was present. Tendon reflexes were normal except that the right knee-jerk could not be obtained. On September 26, eight days after the eruption, the cerebrospinal fluid showed 28 lymphocytes per c.mm., with 0.045% protein. There was slight weakness of the adductors and complete flaccid paralysis of the quadriceps; the knee-jerk was still absent, and wasting had increased to 1 inch in circumference of the thigh. There was no improvement in the paralysis until October 1, when she could just extend the knee and flex the thigh, and the cerebrospinal fluid now showed 16 lymphocytes per c.mm., with 0.03% protein. The vesicles had disappeared, but nocturnal neuralgia still troubled her, although it was controlled by analgesics. Movement gradually improved with massage and exercise, and she had regained about half her power by October 14, although the knee-jerk was still absent.

On October 20, nearly five weeks after the beginning of the illness, the cerebrospinal fluid contained 11 lymphocytes, with 0.03% protein. Gradual improvement followed, and on November 17 it was noted that the right knee-jerk was just present. On December 19 the last lumbar puncture was done and 8 lymphocytes with 0.032% protein were found. Wasting was persistent and she still complained of occasional twinges of pain in the thigh and leg. The knee-jerk had returned almost fully five months after the onset, and power was fair, although she still used a stick.

When last seen about a year after her illness she was symptomless, except that the right leg tired easily. Examination revealed half an inch of wasting in the right quadriceps, persistent scars of the eruption, and great improvement in her mental condition. The right knee-jerk seemed as brisk as the left.

Commentary

These two cases demonstrate an unusual complication of herpes zoster. Although no complement-fixation test was done there was no reason to doubt the diagnosis, as the clinical features and the course were typical. It was considered important to exclude any underlying condition which might have been responsible for the paralysis, since it is well recognized that zoster may occur in other diseases of the spinal cord, particularly in disseminated sclerosis, tabes dorsalis, and cases of cord compression. There were no clinical signs to suggest the presence of any such lesion in our cases, although in Case I the history of dyspepsia and a positive occult blood reaction in the faeces led us to exclude by radiograph spinal metastases from possible carcinoma of the stomach.

The pathology of herpes zoster is still somewhat obscure, as so few cases come to necropsy. Head and Campbell in 1900 in an exhaustive paper mentioned that Bärensprung in 1861 first showed that zoster was a disease of the nervous system associated with changes in the posterior root ganglia. They described their post-mortem findings in 21 cases in which death occurred at all stages of the disease from three days to over two years after the outbreak of the eruption, and concluded that the primary lesion was an acute round-cell infiltration with areas of haemorrhage in the affected posterior root ganglia, and that changes found in the posterior nerve roots and spinal cord were secondary degenerative processes. The fact that Price (1937) gives a similar account of the pathology of zoster without mentioning the existence of any spinal cord lesions suggests that Head and Campbell's ideas are still in the main accepted in this country.

This view has been challenged by the French school, notably by Jean Lhermitte and his collaborators, who in three communications reported acute inflammatory changes not only in the ganglia but also in the posterior roots, the meninges, and the cord itself. In the first of these papers Lhermitte and Nicolas (1924) described the post-mortem appearances of a patient dying of bronchopneumonia seven weeks after the onset of the herpetic eruption. They found perivascular infiltration of leucocytes and mononuclear cells with vascular dilatation and demyelination in the posterior horns of the affected segments. The anterior horns showed atrophic changes in the cells with demyelination of the nerve roots and some lymphocytic infiltration: in spite of this no paralysis was observed clinically. There were no changes in the white matter except for one area in the pyramidal tract in which perivascular "cuffing" was observed. It is of interest to note that the cerebrospinal fluid of this case showed a pleocytosis of 88 lymphocytes per c.mm. on the second day of the eruption. Similar observations were recorded in two subsequent papers (Faure-Beaulieu and Lhermitte, 1929: Lhermitte and Vermès, 1930). In the former, lesions spreading to neighbouring segments were found in the posterior horns. Kinnier Wilson (1940) records similar findings by Nicolesco, Thomas and Laminière, and Schlesinger.

The view that the infection involves the meninges and the cord as well as the posterior root and its ganglion is supported by the frequent occurrence, according to Kinnier Wilson, of a pleocytosis in the cerebrospinal fluid. Both our cases were typical in this respect.

It would appear probable, therefore, that zoster is essentially an acute posterior poliomyelitis involving the whole of what we suggest may be called the "segmental sensory neurone." Although anatomically the root ganglia are placed outside the spinal cord, they consist of cells which have migrated out from the posterior horn, and thus their constant involvement is understandable. The finding of inflammatory changes in the anterior horn by Lhermitte and others is presumably due to the spread of the virus from the posterior horn, and would explain the occasional occurrence of motor lesions in a disease which primarily involves the sensory system.

Since so few cases have been described it is impossible to determine accurately the course and prognosis of paralysis complicating zoster. Our cases, in which identical segments were attacked, ran similar courses. The pleocytosis took many weeks to subside: Case I showed 14 lymphocytes three months after the onset, and Case II 8 cells nine weeks afterwards. When last seen, nine and twelve months respectively after the eruption, neither of these patients had fully returned to normal: Case I was complaining of nocturnal neuralgia in the leg and had a slightly diminished knee-jerk, and Case II showed slight wasting of the affected muscles. The crural paralyses in both Hardy's and Cornil's cases appear to have gradually improved, and in Rocchi's case the paralysis of the obliques had almost disappeared within a year. These cases show that though recovery is slow, satisfactory function can return within a year. The observation of further cases for longer periods would be necessary to determine whether this is the rule and whether complete recovery may not be possible.

Summary

Two cases of lower motor neurone paralysis complicating herpes zoster are described, and the pathology is discussed.

We desire to thank Dr. H. Joules for permission to publish Case I, which was under his care, and Dr. V. C. Robinson for his help in translating the literature.

A. Christie (*J. Pediat.*, 1940, **17**, 502) reports that a follow-up study of children to test the duration of Schick immunity was made with various antigenic materials with the following results. According to the type of material, doses given, and the period between injections and the Schick test, 77 to 95% of the group showed negative Schick reactions in four to twelve weeks. After a four to nine year follow-up period 46 to 88% of the known Schick-negative reactions were found to be still negative and 12 to 54% had become positive. Christie concludes that all children immunized in the first year of life should be Schick-tested again on admission to school, when those who are positive should be given a stimulating dose of toxoid.

BELL'S PALSY AND HERPES ZOSTER

BY

JOHN D. SPILLANE, M.D., M.R.C.P.
Major, R.A.M.C.

Clinical evidence has long led to the belief that the commonest aetiological agent in Bell's palsy is exposure to a cold draught. But its mode of action is obscure, and whether cold alone is adequate or whether it exerts its effect upon an already susceptible nerve has been the subject of much debate. Were cold *per se* the deciding factor one would expect a greater incidence, both total and seasonal. Seasonal figures, however, show no great variation, although it is a fact that one new case is commonly followed by several others at certain seasons of the year (Walshe, 1940). Instances of bilateral, recurrent, hereditary, or even familial peripheral facial paralysis seem to support the idea of a predisposing factor (anatomical or otherwise). On the other hand, the facial nerve seems to be just as susceptible to toxic and infective conditions as to the common draught. Such conditions may be general—for example, polyneuritis—or local, such as tetanus.

When Ramsay Hunt (1907) described herpetic involvement of the geniculate ganglion of the facial nerve he focused attention on the virus of herpes zoster as a possible cause of Bell's palsy. In the syndrome which now bears his name we find the combination of peripheral facial paralysis and a herpetic eruption in and around the external auditory meatus of the same side. Vesicles may also be present on the pillars of the fauces and the anterior two-thirds of the tongue on that side. The subject usually complains of pain in the ear, herpetic vesicles make their appearance, and facial paralysis follows in a few days. This sequence is not constant, and the condition may be ushered in with a painless facial paralysis. The small size and the transient nature of many vesicles, and their frequently hidden position in the meatus, make geniculate zoster a condition easily missed. The eruption may precede the paralysis by a week or more, and many cases must then be labelled Bell's palsy. The obvious question that arises is whether Bell's palsy is ever due to invasion of the geniculate ganglion by the zoster virus. It is not difficult to imagine geniculate zoster without the cutaneous eruption. Aitken and Brain (1933) were able to demonstrate by complement-fixation tests that in the blood serum of patients with geniculate zoster there were antibodies to the zoster virus. The sera of twenty-two cases of Bell's palsy were found to contain zoster antibodies in only four instances. Serological evidence therefore points to zoster infection as a probable though uncommon cause of Bell's palsy. It is thus of interest to record a recent clinical experience which supports this view.

In March, 1940, a number of cases of herpes zoster were encountered. They occurred in crops of two, three, or four at a time, presented no unusual features (with one exception), and ceased to appear at the end of the month. In all there were perhaps twenty cases; probably others occurred but were not seen. That these cases represented a small epidemic is supported by their rarity during other months of that year. Many men were but mildly affected and did not take to bed. A few, however, showed general disturbance, with a profuse painful eruption, and were admitted to hospital. In one ward, at one time, there were five such cases.

Case Reports

Case 1. Herpes Zoster involving Th. 9 Segment on Left Side.—The illness was ushered in with headache, malaise, and a bout of sickness four days before admission. Burning pricking pain in the skin of the affected segment followed, and a typical herpetiform rash subsequently developed. During the acute stage there was pyrexia of 101°, but this subsided to normal in three days. There was no glandular enlargement: a white cell count was normal (8,700 cells per c.mm.), but there was a slight lymphocytic reaction in the cerebrospinal fluid (15 lymphocytes per c.mm.); the protein content was normal (25 mg. per 100 c.cm.). Pituitrin injections were ineffective. Recovery was uneventful.

Case 2. Herpes Zoster affecting Th. 7 and 8 Segments on Left Side.—Anorexia, lassitude, and pyrexia (100°) preceded the onset of neuralgia and the appearance of the rash by three or four days. The latter was profuse, and much pain was experienced for a time. Lumbar puncture was not done. There were no enlarged glands. Pituitrin was without effect.

Case 3. Herpes Zoster involving L. 1 and 2 Segments on Right Side.—In this case the rash was rather late in appearing. The patient experienced severe pains and dysaesthesiae for a week before its arrival. A diagnosis was made of meralgia paraesthetica before the vesicles were detected. There was a curious frequency of micturition, with pyrexia (99°), shivering attacks, and discomfort over the bladder. The urine was normal on several examinations, however, and cultures were negative. The remote possibility of vesical herpes zoster was considered. At first the rash was practically confined to the first lumbar segment, but later it spread to involve the adjacent area below. A normal cerebrospinal fluid was found and there were a few painless glands in the inguinal regions. Pituitrin was not beneficial.

Case 4. Herpes Zoster involving Th. 6 Segment on Left Side.—This patient, who came from the same unit as Case 3, developed pain, pyrexia (99°), and a rash one day before admission. The vesicles were sparse, but there was much neuralgia and cutaneous hyperaesthesia. Three days after the rash had appeared it would have been impossible to recognize the true nature of the eruption, which could well have been missed and the condition labelled "intercostal neuralgia." Lumbar puncture revealed a normal fluid. Pituitrin apparently reduced the pain and discomfort.

Case 5. Herpes Zoster of the Trigeminal Nerve with Ipsilateral Facial Paralysis.—This patient, aged 24, was admitted to hospital with a history of severe pain in the left side of the face for three or four days. A profuse herpetiform rash developed during the night before admission. Within twenty-four hours numerous large coalescing blisters were clustered over the lower half of the left side of the face. There was much redness, swelling, and oedema of the tissues, with a brisk general reaction. The temperature remained at 100° for forty-eight hours and malaise and anorexia were marked. The vesicles were distributed over the areas supplied by the maxillary and mandibular divisions of the trigeminal nerve; a few were clustered together on the lower eyelid, and others on the chin just crossed the midline. There were no vesicles or other form of eruption in the auricular zone. The tympanic membrane, external auditory canal and meatus, concha, tragus, antitragus, helix and fossa, and posterior surface of the lobe of the ear were entirely normal. There was no earache throughout the course of the illness. In the area of the ophthalmic division no eruption appeared, but tactile and painful sensations were diminished. This was especially marked in the supra-orbital and nasociliary areas. Owing to the profuse rash it was impossible to be certain whether there was any sensory change over the areas subserved by the second and third divisions of the fifth nerve. Later in the illness tactile and painful sensations were diminished. The corneal reflex was almost absent, but a feeble conjunctival response persisted. The mucous membranes of the cheek, lips, gums, tongue, and fauces were normal. The sensation of taste was normal and there was no weakness of masseter or temporal muscles.

On the morning of the fifth day in hospital, when pain had subsided and the rash was drying up, the patient awoke with a complete peripheral facial paralysis on the left side. There had been no earache and the ear was normal. The mucous membranes of the mouth were still healthy. The sense of taste, however, was almost completely absent over the anterior half of the tongue on the left side. The patient was unaware

of this hemiageusia. Blunting of sensation over the left side of the forehead and cheek was still present. He remained in hospital for several weeks and made a complete recovery. The sensory changes persisted for a few more days: the hemiageusia disappeared between the nineteenth and twenty-third days of the illness, while the facial paralysis had practically gone three weeks after its appearance.

Case 6.—While the above five cases of herpes zoster were in hospital I saw a case of Bell's palsy in the out-patient department. It was a typical peripheral facial paralysis in all respects and there had been no pain or rash or general reaction. The man made a good recovery within a month He was employed in the same unit as the first patient (Case 1), and I learned that there had been two or three other instances of herpetic eruption there. Cases 2, 3, and 4 came from separate units, but their quarters were adjacent. I saw several other cases of herpes zoster from the same unit as Case 5. The observation of Case 6 during the height of the epidemic becomes significant when it is stated that only two instances of Bell's palsy have been seen at this hospital during the past twelve months. The second occurred in September, 1940

Commentary

The first interesting feature of these cases was the development in one of them, on the eighth day, of an ipsilateral facial paralysis. The herpetic eruption was confined to the second and third divisions of the trigeminal nerve, but there was diminished sensation to touch and pain over the first division. *No auricular zoster developed* Undoubtedly, then, the herpes virus had invaded both the Gasserian and geniculate ganglia. The former resulted in the facial eruption and the latter in the facial paralysis. Whether these manifestations appeared in order of the involvement of these structures can only be surmised. We do not know what interval elapses between the time of infection of the ganglion cells and the appearance of the rash, but it is quite possible the virus attacked the geniculate from the Gasserian ganglion by way of the superior superficial petrosal nerve. It was not until the infection reached the cell stations in the geniculate ganglion of the fibres of the chorda tympani nerve that taste was affected.

The absence of auricular herpes is especially interesting. It indicates that herpetic invasion of the geniculate ganglion can take place without any cutaneous manifestation in the distribution of its sensory fibres. Facial palsy may be the only sign. Hemiageusia would probably be a more frequent sign in facial paralysis due to geniculate ganglionitis than in that due to a lesion arising at the stylomastoid foramen.

Another interesting feature was the isolated occurrence in the same unit as one of the herpes zoster patients of a typical Bell's palsy; this suggests a common aetiological agent. The possibility of coincidence cannot, of course, be denied, but it remains that this case of Bell's palsy was the only one observed at the hospital for a period of nine months. When considered in the light of Case 5—in which zoster and facial paralysis were present simultaneously—the suggestion of a virus origin of Bell's palsy becomes highly probable.

Such findings suggest the possibility of analogous lesions in other sensory nerves. The abortive nature of the rash in Case 4 brought to mind the condition of intercostal neuralgia, and the lumbar neuritis in Case 3 suggested a diagnosis of meralgia paraesthetica during the week preceding the rash. Some cases of facial neuralgia may be due to herpetic Gasserian ganglionitis.

Summary

In a small outbreak of herpes zoster one case of combined trigeminal and geniculate zoster was encountered. It was characterized by facial herpes and an ipsilateral facial palsy. The former preceded the latter by five days. No auricular or faucial herpes developed. Facial paralysis and hemiageusia were the only signs of geniculate involvement. During this zoster epidemic there occurred the only instance of Bell's palsy seen at the hospital for a period of nine months. The patient came from the same unit as one of the zoster cases.

This evidence supports the view that some cases of Bell's palsy are due to herpetic infection of the geniculate ganglion.

AN OUTBREAK OF TRICHINIASIS IN WOLVERHAMPTON AND DISTRICT

A CLINICAL ACCOUNT OF SEVEN CASES

BY

J. E. STANLEY LEE, M.B., F.R.F.P.S.G., F.R.C.S.Ed.

Medical Superintendent, New Cross Hospital, Wolverhampton

Acute trichiniasis is produced by the embryos of *Trichinella spiralis* during their migrations from the human intestine to the voluntary muscles, and, though extremely rare in Great Britain, the disease is not uncommon in America and Germany. The life history of the parasite is adequately described in the standard textbooks, and, as is well known to medical practitioners and students, infection in man is acquired by eating raw or undercooked pork. The clinical features of the cases described in this article were distinctly unusual and caused some difficulty in diagnosis. Nephritis, pneumonia, renal damage, influenza, pyrexia of unknown origin, suspected enteric fever, and pyelitis were the conclusions arrived at before admission of the patients to New Cross Hospital.

The predominating signs and symptoms consisted of oedema of the eyelids, headaches, conjunctival haemorrhage or injection, mental torpor with lethargy, drowsiness, confusion, and slowed cerebration, heaviness in the limbs, generalized aches and pains, muscular tenderness and stiffness, disturbances of reflex action, paresis, and severe constipation. Vomiting occurred at the outset in two cases and colic in one. My colleagues and I were aware that we were confronted with a distinct clinical entity which was hitherto unknown to us. Blood urea investigations were carried out in the early cases and yielded results which fell well within normal limits. Examination of the blood was next decided upon, and the presence of eosinophilia was discovered. The patients were then seen in consultation with Dr. J. H. Sheldon, consulting physician to New Cross Hospital, who put forward a tentative diagnosis of trichiniasis.* Clinically this disease is generally described in three stages in accordance with the life history of the parasite. Carmichael Low and Hamilton Fairley (1933) state that for the first week during the invasion period gastro-intestinal symptoms develop, with nausea, vomiting, colic, and diarrhoea with perhaps blood and mucus; then when migration of larvae begins myositis of the tongue, laryngeal, and intercostal muscles, and the diaphragm occurs, giving rise to difficulty of swallowing, speech, and respiration. The muscles of the jaws, arms, legs, and abdomen may also be involved, with stiffness and pain: the affected areas are extremely tender and hard to the touch. Oedema, especially of the face, urticaria, leucocytosis with high eosinophilia, prolonged remittent fever (102° to 104° F.), and sweating are said to be characteristic. Cachexia and subcutaneous oedema

* A preliminary account of the present epidemic is given by Dr. Sheldon in the current issue of the *Lancet* (February 15).

and finally, during the period of larval encystment, death may take place from toxaemia, with respiratory disturbance and coma. The fact that many of these symptoms were not shown by the patients under consideration threw doubt upon the diagnosis, and the high incidence of the disease in women also caused suspicions to be directed elsewhere for a time. However, on January 24 biopsy of the pectoral muscle was performed, and the diagnosis was established by the identification of the coiled-up embryos of *Trichinella spiralis* in the characteristic lemon-shaped areas. There was little or no capsule formation, and Dr. Paul B. Beeson of Harvard, who was shown the specimen and confirmed the diagnosis, was of the opinion that the parasite had only just reached the muscle. On January 27 further confirmation was obtained when another successful biopsy was performed.

Case I

A previously healthy 21-year-old married woman noticed puffiness of her eyelids on waking on the morning of December 22, 1940. On the same day she developed severe temporal headache and pain in the left loin. The temperature was normal; there was no cough and no diarrhoea. Vomiting occurred once daily from December 23 to 25 inclusive, and aching pains in the limbs supervened during the same period. Insomnia was present on December 25 and 26. The swelling of the eyelids and the aching pains in the limbs persisted, and she was admitted to hospital on December 28.

Examination showed marked puffiness and swelling of the eyelids and injection of the conjunctival vessels, and the facies was that of a woman twice her age. The only other abnormal physical signs present were a few crepitations in the left lung. There were no abnormal constituents in her urine; the blood pressure was 126/84, the temperature 99°, the pulse 104, and the respirations 24; the blood urea was 37 mg. per 100 c.cm. The mental attitude was distinctly unusual; she complained of feeling "all fuddled," took no interest in her surroundings, and felt very miserable. She showed signs of impairment of memory, and appeared to be dazed and somewhat confused.

Gradual improvement took place, and she was discharged from hospital on January 11, 1941, free from symptoms.

Case II

A housewife aged 36 years developed severe headache, backache, and pains in the left groin on the morning of December 19, 1940. During the afternoon of the same day she observed that her eyelids and the upper part of her face were becoming puffy and swollen. The swelling of the eyelids continued to increase slowly, and aching pains appeared in the limbs and neck on December 21, when the arms felt too heavy to lift, and all her muscles ached to a severe degree even when moving. In spite of her illness she left home to do some shopping, and on returning home in a low-spirited and depressed condition the severity of the headache and backache together with the tiredness of the limbs was such as to cause her to drop into a chair in a fainting condition. There was no history of diarrhoea.

On admission to hospital on December 22 the patient appeared to be in a state of abject misery, was obviously ill, and had extensive swelling and puffiness of the eyelids together with conjunctival haemorrhages. The oedema of the eyelids was sufficient to interfere with vision, and she was unable to see a coin placed in her hand; the temperature was 100°, the pulse rate 120, and the respirations 24. Areas of tenderness were present in both loins, in the back, and to a less extent in the abdomen. Stiffness of the neck, which was most noticeable when she sat up, occurred on December 22 and lasted for three days. Vomiting was present on the second and fourth days after admission; the urine was normal and the blood pressure was 160/110. The patient's mental attitude was abnormal; there were evidences of confusion and slowed cerebration, and when addressed she had to think for some time before she was able to understand what was required of her.

During the night of December 26 loss of power in the left leg supervened, and next morning this limb could not be moved, being described by the patient as heavy and numb. This paresis persisted for twenty-four hours, after which gradual improvement took place. The knee-jerks and ankle-jerks were present; the left plantar reflex was practically absent, and the right easily flexor.

Constipation was pronounced and insomnia troublesome during the first week in hospital. The blood urea was 33 mg. per 100 c.cm. and the urea-clearance factor 88% of normal. Discharge from hospital took place on January 11, 1941, when the patient was free from symptoms.

Case III

A married woman aged 29 years became ill on December 22, 1940, the initial symptoms being supra-orbital headache and swelling of the eyelids. She sought medical advice and was thought to have nephritis. On December 24 the swelling of the eyelids became much worse—the face and forehead were affected; the head felt much larger than normal, and headache assumed a violent character. Abdominal aches and pains next developed; there was no vomiting and no diarrhoea, and the urine was stated to be scanty and dark in colour.

On admission to hospital on December 25 pronounced oedema of the face, eyelids, and frontal area of the scalp, together with chemosis and conjunctival haemorrhages, was noted. The temperature was 102°, the pulse rate 120, and respirations 24; stiffness of the neck and some muscular tenderness were also present. The urine, which was normal on admission, contained a large amount of albumin on December 28 and 29, and albuminuria reappeared on January 1, persisting for six days.

Loss of power in the left arm and to a less extent in the right supervened on December 29, and this paresis, which was not a true paralysis, persisted for three days. During mealtimes, while using a fork, evidence of true incoordination in the left arm was noted. Drowsiness and lethargy developed on December 31, cerebration became slow, the memory was impaired, and mental confusion existed; finding everything an effort, the patient felt miserable. This state of mental torpor continued for four days, during which time she did not recognize her husband and showed a complete lack of interest in her surroundings. Low pyrexia of an irregular type continued for eleven days, and severe constipation necessitated enemata and aperients. The urea-clearance test showed the blood urea to be 40 mg. per 100 c.cm., and the urea-clearance factor was 100% of normal.

Convalescence was gradual, and the patient was discharged on January 14, 1941, free from symptoms.

Case IV

A housewife aged 36 years had a cold in the head on December 16, 1940, and three days later sought medical advice on account of swelling of her face, eyes, and lips. Violent headache set in simultaneously, being accompanied by severe pains in the lower abdomen, most pronounced in the left iliac region. Retention of urine and complete constipation occurred on December 19 and 20. Weakness of the left hand appeared on the third day of her illness; there was no history of diarrhoea.

On admission the clinical picture was that of uraemia: drowsiness and lethargy were extremely well marked; inability to sit up in bed existed for two days after admission; slight oedema of the upper part of the face and eyelids was still visible; and retention of urine, lasting for four days, was present, catheterization being necessary. The urine contained a trace of albumin, which disappeared in the course of a few days; the blood pressure was 104/90, and severe constipation called for treatment.

There was paresis of the left hand; the grip was weak, incoordination was detected by the finger-nose test, and with the exception of the biceps-jerk all the left arm reflexes were absent. The right arm reflexes were sluggish, both knee-jerks were practically absent, and the plantar reflexes were flexor. No muscle tenderness was elicited, and there was no disturbance of joint sense. The blood urea was 46 mg. per 100 c.cm., and the urea-clearance factor 160% of normal.

Convalescence was uninterrupted, and the patient returned home on January 15, 1941.

Case V

A housewife aged 37 years complained of severe headache, giddiness, and swelling of the eyelids on December 14, 1940. Heaviness of the legs developed at the outset of the illness; they seemed to droop when attempts were made to raise them, and felt as if they were made of lead. To a minor extent similar sensations were experienced in both arms. Oedema of the eyelids persisted for some time, and on December 18 was remarked upon by a relative. Vomiting started on December 20 and ceased on December 24; pyrexia, sweats, and loss of memory were present, but no abdominal pains and no diarrhoea.

On admission to hospital on December 28 the clinical picture was that of tuberculous meningitis; some degree of coma, with signs of meningeal irritation, cervical rigidity, and slight head retractions, was noted. At intervals the patient gave vent to a peculiar high-pitched piercing "meningeal" cry, of which she was conscious. Kernig's sign was positive on both sides; the right plantar reflex gave an extensor response, whereas the left was flexor; the abdominal and ankle reflexes were absent, the knee-jerks practically so, and examination of the optic disks revealed slight papilloedema. The skin was moist, the face puffy, and incontinence was present.

Lumbar puncture revealed clear colourless fluid, very scanty lymphocytes only in films—1 cell per c.mm.—chlorides 710 mg. and protein 10 mg. per 100 c.cm., and globulin within normal limits. The temperature was 101°, the pulse rate 120, respirations 26, the blood pressure 100/80, and the blood urea 35 mg. per 100 c.cm.; the urine contained no abnormal constituents. The hands and legs became oedematous on December 29, and three days later considerable muscle tenderness was present, pinching of the calves causing the patient to flinch even though she was incapable of answering questions. Both plantar reflexes were now extensor; the legs were drawn up, and she appeared to be gravely ill. This stage of meningeal irritation passed off gradually; control of the sphincters was regained on January 4, 1941, but drowsiness and lethargy remained for a time.

Examination on January 9 revealed no nystagmus; the disks were normal, and the pupils equal and reacting; the arm muscles were feeble and all reflexes absent, and there was a gross incoordination of the arms with severe dysdiadokokinesia, suggesting a cerebellar lesion. Joint sense was normal in the arms but absent in the legs; the knee-jerks were sluggish and the ankle-jerks were absent; the left plantar reflex was flexor and the right plantar reflex doubtful. The heel–shin test was badly executed and the abdominal reflexes were absent. Constipation was extremely troublesome in spite of aperients and enemata.

By January 16 the patient was greatly improved and her mentality was normal; muscle power in the arms was normal, but there was still incoordination in the right arm; oedema of the left foot and leg was present, the knee-jerks were sluggish, and the plantar reflexes were flexor. A week later constipation still persisted and some degree of faecal impaction occurred; there was considerable loss of postural tone on holding the arms outstretched, and gross incoordination of the right arm with some degree of dysdiadokokinesia; the arm reflexes were slightly increased, and all others were normal. On January 24 biopsy revealed the presence of the embryos of *Trichinella spiralis*. Atrophy of the extensor muscles of the right thigh and calf muscles was noted on January 29; nystagmus was also present for the first time. The patient was unsteady when she sat up and appeared to have some degree of ataxia, which, together with other findings, suggested a cerebellar lesion.

Case VI

A 36-year-old labourer became ill on January 4, 1941, with severe persistent headache and irritability. He avoided conversation with others, resented being disturbed, and retired to bed on account of general weakness. On the 9th he was told that his face was swollen, and next morning he complained of heaviness of his right leg, which was swollen and puffy. Drowsiness supervened and an attack of acute gastro-enteritis lasting for twenty-four hours ensued.

On admission to hospital on January 14 difficulty was experienced in obtaining an accurate history owing to the mental torpor which existed; cerebration was slow, the memory was impaired, and the patient, who appeared to be somewhat bewildered, wore a strange and puzzled expression. He was lethargic, drowsy, disoriented, and his speech was rambling in character. Haemorrhages into the distal end of the finger-nail beds taking the form of crescentic bands of ecchymosis were noted, together with conjunctival haemorrhages and oedema of the eyelids and the right leg. The temperature was 101.4°, the pulse rate 112, and respirations 20; the urine contained abundant albumin, and muscle tenderness was detected in the arms, calves, shoulders, and the right intercostal spaces. Good muscle power was present in both arms, some incoordination of the right arm was shown by the finger–nose test, and with the exception of the right biceps-jerk all arm reflexes were absent. The knee-jerks were sluggish, the plantar reflexes normal, and the muscle–joint sense was somewhat impaired in both legs. The heel–knee test revealed slight incoordination in the right leg, and Kernig's sign was positive on both sides.

Lumbar puncture revealed colourless fluid, scanty lymphocytes in films—1 cell per c.mm.—chlorides 700 mg. and protein 20 mg. per 100 c.cm., and globulin within normal limits. A search for the larvae of *Trichinella spiralis* in the cerebrospinal fluid was unsuccessful. During the first week in hospital constipation was marked and the tongue was dry; the mental confusion continued, the headache gradually diminished, and the mild pyrexia subsided; urinary incontinence occurred on two occasions. Biopsy of the pectoral muscle was performed under local anaesthesia on January 27 and the coiled-up embryos of *Trichinella spiralis* were identified.

Case VII

On January 18, 1941, a married woman aged 36 years was seized with pain in the right loin which travelled into the right side of the abdomen and then became generalized. The pain persisted, and vomiting occurred on January 20 and continued. On the next day severe supra-orbital headache developed, accompanied by knife-like pains down both sides of the face; the face became slightly swollen, leg pains appeared, but there was no diarrhoea. She was admitted to hospital on January 23, and was said to be suffering from pyelitis.

The temperature was 102°, pulse rate 120, respirations 18, and there was pronounced tenderness, with some degree of resistance, in the right loin and lower abdomen. Slight oedema of the eyelids and mild injection of the conjunctival vessels were observed: muscle tenderness was present in the calves and shoulders, but there was no paresis. Leg reflexes were normal, but all the arm reflexes were diminished. The urine contained a trace of albumin, a few pus cells, and very scanty *B. coli*: these findings did not appear sufficient to account for the illness, and questioning failed to elicit any urinary symptoms. Puffiness of the eyelids and conjunctivae became more marked during the first two days in hospital, and the temperature returned to normal by lysis four days after admission. The leucocyte count revealed an eosinophilia of 24%.

Table enumerating the Leucocytes

Case	Date	White Cells per c.mm.	Polymorphs %	Lymphocytes %	Eosinophils %	Monocytes %	Basophils %
I	31 12 40	5,200	63	25	8	3	
	9 1 41	9,600	64	25	7	4	
II	31 12 40	14,800	73	13	11	3	
	9 1 41	11,600	73	19	8		
III	30 12 40	19,400	85	12	2	1	
	9 1 41	6,100	57	39	1	3	
IV	31 12 40	12,000	79	14	7		
	9 1 41	12,400	68	27	3	2	
V	30 12 40	11,800	84	12	3	1	
	9 1 41	9,200	70	20	9	1	
VI	23 1 41	15,000	43	22	33	1	1
	15 1 41	16,400	43	6	49	2	
VII	27 1 41	11,600	74	16	5	3	2
	27 1 41	12,000	61	13	24	2	

Summary and Conclusions

Seven cases of acute trichiniasis presenting atypical features have been described and attention has been drawn to the manner in which this disease may simulate nephritis,

uraemia, tuberculous meningitis, and pyelitis. The outstanding symptom in all cases was oedema of the eyelids, and this, in conjunction with the presence of eosinophilia, may be regarded as diagnostic. The abnormal mental state appears to have been inadequately described in the past, and is worthy of special note. Haemorrhages into the conjunctivae and nail-beds constitute strong supporting evidence, and these signs appear to be attributable to larval embolism. Definite indications of involvement of the central nervous system were observed, and in one case the clinical signs suggested a cerebellar lesion, possibly also of embolic origin. Muscle tenderness was present in most cases, and a surprising feature was the existence of constipation, which was exceedingly troublesome and resulted in faecal impaction on one occasion.

I desire to express my thanks to Dr. J. H. Sheldon, consulting physician, New Cross Hospital, Wolverhampton, for his co-operation and help; to the resident medical officers for their clinical assistance; and to Mr. K. R. Vasey.

TRICHINIASIS IN HERTFORDSHIRE

BY

LAWRENCE P. GARROD, M.D., F.R.C.P.

Pathologist to an E.M.S. Laboratory

AND

DONALD MACLEAN, M.B., Ch.B.

The following brief account of some cases of trichiniasis recently diagnosed in Harpenden, Herts, may be of service to others called upon to recognize this disease.

Information that trichiniasis had appeared in this country reached one of us on February 1; in the practice of the other there had been several cases presenting unusual features, of which the most arresting was oedema about the eyes. A connexion between these facts was suspected, and blood films from two of the cases were examined forthwith. Each showed an extreme eosinophilia. Five typical cases were then investigated further. Their clinical histories are as follows:

Case Histories

Case 1.—Female aged 44. Had been feeling ill for three days before January 23, when she first noticed puffiness of the eyes and had general muscular pains; she also complained of severe temporal headache. On January 24 her temperature was 101° and her pulse 100; she had a harsh barking cough and marked oedema of the eyelids. Physical examination revealed nothing else abnormal, and there was no albuminuria. Fever of 99° to 101.6° has now persisted for sixteen days: muscular pain, chiefly affecting the calves of the legs, neck, and shoulder girdle, is now diminishing. She also complains of vague abdominal discomfort, sometimes amounting to pain.

Case 2.—Male aged 36. Onset on January 21 with swelling of the eyelids and face, temporal headache, and pain, particularly in forearms and legs. No abnormal physical signs except muscular tenderness; no albuminuria. Fever persisted for three or four days, muscular pain for about ten days, accompanied later in the forearms by oedema. Recovery complete in a fortnight.

Case 3.—Female aged 34, the wife of the foregoing patient. Had an illness with identical features at the same time, but was less ill; continued her ordinary life, and was neither examined nor treated.

Case 4.—Male aged 53. Onset on January 31, with oedema of the eyelids; no headache and no muscular pain. On February 1, temperature 100°, well-marked oedema of the eyelids; physical examination otherwise negative; no albuminuria. Temperature since has varied between 99.6° and 101.6°, and some muscular stiffness and a feeling of ill-being have developed: this attack has now lasted eight days and continues.

Case 5.—Female aged 44. Had a headache for two days before January 21, when her eyes became puffy and she had pain in the muscles of the neck, arms, and legs, and some vague abdominal discomfort. First seen on January 23, when she had a temperature of 100° and marked oedema of the eyelids. Physical examination negative; no albuminuria. Pain and a feeling of ill-being lasted for ten days, by which time the oedema had also nearly subsided. She was quite well within a fortnight.

Pathological Investigations.—Differential leucocyte counts gave the following results:

	No. of Days since Onset	W.B.C. per c.mm.	Percentage of Eosinophils	Eosinophils per c.mm.
Case 1 ..	12	13,400	28	3,752
Case 2 ..	14	8,000	27	2,160
Case 3 ..	14	11,600	27.5	3,190
Case 4 ..	5	12,000	31	3,720
Case 5 ..	14	17,800	47	8,366

There was thus a pronounced eosinophilia in all cases, although in one the duration of the disease had been only five days, and in three the attack had been brief and was clinically over when the counts were made.

Muscle biopsy was performed in three cases, small pieces of the deltoid being removed for us under local anaesthesia by Mr. Michael Harmer, whose help we gratefully acknowledge. In Cases 2 and 5 no embryos were present, but a single coiled embryo lying among the fibres was discovered in the specimen from Case 1. These examinations were made on the same day of the disease as the blood counts.

In Case 4, the most recent, two stools passed after 4 grains of calomel were examined for adult worms with no result, and in 10 c.cm. of blood lysed in an excess of distilled water and centrifuged no embryos were found.

Dietetic History.—All these patients could recollect having eaten sausages during the fortnight preceding the onset of their illness. Two of them had been in Birmingham and one in London during this period, and might have acquired the disease there; but its local origin is certain in Case 5—this patient having had no meals away from home—and particularly in Case 3, which patient had not only been continuously at home but had admitted having eaten two locally bought sausages *raw* on or about January 14. Her husband, Case 2, ate four of the same sausages cooked.

Other Cases.—One of us (D. M.) has seen several similar cases, all during the last three weeks of January, in which no laboratory investigations were made. We mention in passing that one of these patients gave blood for transfusion on the day before his illness became noticeable: the number of embryos so transmitted would be small, but it should presumably be recognized as inadvisable that anyone suspected of having trichiniasis should act as a blood donor. It is not assumed that these were necessarily cases of the disease, and, indeed, we have reason for believing that the features of mild trichiniasis may be imitated by some other condition. A man complaining of fever and headache, who three days later developed conjunctival oedema but no muscular pain or other complaint, had an eosinophil count of only 132 per c.mm. on the sixth day after the onset. He had eaten sausages on several occasions, and his may be a case of trichiniasis in which eosinophilia has failed to develop. This explanation is almost impossible in another case under the care of Dr. K. H. C. Hester, to whom we are indebted for permission to mention it. She is a woman aged 48 who has developed marked oedema of the eyelids in association with a febrile illness having no other localizing features except upper respiratory tract catarrh. Not only is her eosinophil count merely 56 per c.mm., but she is a strict vegetarian, and close questioning has brought to light not even the possibility that she might have consumed meat in a sandwich without knowing what it was.

Commentary

The finding of a trichinella embryo establishes the diagnosis in Case 1 and thus proves the existence of the disease in this locality. The other four cases are clinically similar, and all exhibit an eosinophilia of the same order. There is no other febrile disease of such duration in which an eosinophilia of this degree occurs: during a known epidemic an eosinophil count of over 2,000 per c.mm. in any case with the clinical features of trichiniasis is almost certainly diagnostic.

A detailed analysis of the clinical features of so few cases is not called for, but the following points may be noted. The only constant feature is oedema of the eyelids, and maximum stress should be laid upon this in encouraging the search for further cases, although, as we have suggested, this sign should not be taken as pathognomonic. Severe headache localized just above the eyes and quite unrelieved by ordinary sedatives is common, as is a feeling of general ill-being. Muscular pain and tenderness are variable, and were accompanied in only two of these patients by recognizable oedema. Linear subungual haemorrhages were not observed. In no case was there any clear history of gastro-intestinal disturbance preceding the stage of invasion. Three of these cases were very mild, with a duration of little more than a week, and the remaining two, although of longer duration, are of only moderate severity. In such comparatively light infestation the examination of blood and stools for parasites is very likely to be fruitless. The same may be said of muscle biopsy unless the specimen is of adequate size and taken from a carefully chosen site. Out of consideration for patients who submitted to this operation rather in the public interest than for any benefit to themselves, the incisions made were small and the fragment obtained amounted to not more than about 0.1 gramme of muscle. Were we faced again with the need for proving the existence of this disease, we should advocate identifying a point of maximum tenderness, which is usually found near a tendinous insertion, and the excision therefrom of a strip of muscle at least 1 cm. long.

The source of the infested meat which must have been consumed by these patients is not yet known, nor is the distribution of other cases, if any, in the neighbourhood. It is certainly not confined, as we understand it has been elsewhere, mainly to people of the artisan class; on the contrary, none of these five is an insured patient and some of them are well-to-do. The mere fact that trichiniasis exists in a locality so remote from Wolverhampton—the principal area known at the moment to be affected—appears worthy of immediate record, since it strongly suggests that further cases may be recognized elsewhere as soon as their possibility becomes known.

We are indebted for confirmation of the diagnosis by muscle examination to the Institute of Agricultural Parasitology, St. Albans, which is the consulting laboratory for parasitology to the E.M.S.

J. L. Thorner (*Arch. Pediat.*, 1940, **57**, 437) records an abortive attack of measles in a female infant whose mother did not develop measles until nineteen days after delivery. As the mother had been nursing the child not only during the acute stage of the attack but also during convalescence, it was hoped that antibodies had been transferred through the milk, but to insure attenuation 15 c.cm. of whole blood was injected intramuscularly and only an abortive attack of measles ensued. Measles during the first six weeks of life is uncommon, but previous examples have been recorded by Musser (1927), Kohn (1933), Cogne (1924), and Ronaldson (1926).

Clinical Memoranda

Neurological Complications of Serum Therapy

The publication of the article on neurological complications of serum therapy by Drs. Thompson and Tombleson in the *Journal* of June 22, 1940 (p. 1015), prompts me to record my own personal case.

CASE REPORT

On June 3 or 4, 1939, I had a severe attack of dysentery. On the first day microscopical examination of my stools revealed plenty of Charcot-Leyden crystals, but no amoebae or cysts: characteristics of bacillary dysentery stools were not found in it. Moreover, I had had definite amoebic attacks once or twice before. Amoebic infection was diagnosed and injections of emetine hydrochloride were given, but there was no improvement after three 1-grain injections. Further examination of the stools revealed a bacillary infection; cultural examination was not done. Anti-dysenteric serum was then suggested. I generally test a patient's sensitivity to serum by giving him a very small preliminary dose intradermally, and I asked my attending physicians to test me in that way beforehand. The test was done: a little while after the test a big local wheal and very scratchy urticarial rashes broke out all over my body. Seeing that I was hypersensitive I refused to have the serum. During the next two or three days my symptoms did not abate with medicinal treatment and I lost a good deal of blood with stools: consequently it was decided that I must have serum. On June 12 the first dose (20 c.cm.) was injected subcutaneously in my right thigh, the only untoward effects being extensive and itchy rashes all over the body. On the 13th I had another dose of 20 c.cm. No rashes appeared, and I began to show signs of improvement. On the 14th I was practically cured, and felt very well. I went out on the 16th to see an urgent case.

On the 17th extensive rashes again appeared. I took a calcium injection and remained indoors for two days. On the 19th I had to go out to see some cases. Throughout the whole day I felt well, but in the afternoon had some malaise, with stiffness all over the body, just as before an attack of influenza or malaria, and I thought that a little exercise might help to pass it off. During a game of badminton I felt great pain in my back between the shoulder-blades: it radiated over both the shoulders and down the arms and forearms. I had to stop, and went to bed after taking a couple of aspirin tablets. The night passed without much trouble. The next morning I felt better except for some pain in the shoulders and arms. I visited my hospital patients as usual, but suddenly felt an excruciating pain between the shoulder-blades, radiating over both shoulders and down the arms. This completely incapacitated me. I was driven home very slowly and gently, as the slightest jerk aggravated the already excruciating pain to such an extent that I thought I would die before reaching home. A doctor was immediately sent for, and on arrival he gave me 1 ½ grain of morphine, which alleviated the pain slightly. I was confined to bed for three weeks, suffering extreme agony, unrelieved by anything but morphine, which had only a slight and temporary effect. For a few days my temperature rose a little, and I was delirious for many days, mostly at night (a confused state of mind lasted for about six weeks). Within a week of the first appearance of symptoms the muscles around my shoulders, especially of the right—the deltoid, supraspinatus, upper parts of biceps, and triceps—had shrivelled up to such an extent that the right shoulder and the upper part of the right humerus were left covered by mere skin and a few fibres of muscles, which could be felt like strands of thread on the bone. The supinator muscles of the forearm and the first dorsal interosseous of the palm were also more or less shrivelled up. All these muscles of the left arm were affected, but to a much less degree than those of the right. My right arm became completely paralysed, but the left could be moved with difficulty. There were patches of anaesthesia, hyperaesthesia, and paraesthesia on the skin of both the upper limbs. The left vocal cord was also affected. All these paralyses, and the atrophy of the muscles, occurred within a week or ten days. The pain was

intense, with but slight remission from time to time, and I hardly had any sleep for three weeks, during which period I lost nearly 3 stone.

At this stage I was transferred to Calcutta, a distance of 475 miles, for a course of hospital treatment. My pain did not abate for another three weeks, and only morphine gave the slightest relief. At this time cobra venom was tried. The first dose was injected probably on August 1, 1939, and this had a magical effect. Pain abated and I slept straight off for some hours. Thereafter the pain returned off and on, but the severity and duration grew gradually less, and I made an uneventful recovery. I was discharged from hospital by the middle of September, but had electrical treatment and massage for a further month in the out-patient department before returning home. Partial paralysis of both arms and of the vocal cord still persisted when I was discharged. At this time I could raise my arms only up to the shoulders; the atrophied muscles had grown, but were still far from their normal size, and my voice, though much better, was very weak and could be heard only by those near me. At the time of my discharge the specialists said it would be at least six months before my voice was restored (as my left vocal cord was still completely paralysed) and the atrophy and paralyses of my arms would disappear. Here I cannot help mentioning the interesting fact that after my discharge from hospital an ayurvedic practitioner took me in hand, and in less than three weeks my voice was completely restored and my arms got so much better that I could raise them straight to the sides of the head, though with some difficulty; other arm movements still remained restricted.

After nearly fifteen months I still occasionally feel some pain around my right shoulder and arm. A small portion of the posterior part of the right deltoid muscle has not yet fully regenerated, but the movements of the arms are practically normal. A sense of constriction round the right arm (as if a tourniquet was tightly wound round the limb spiral fashion from the shoulder to the finger-tips) and a sense of congestion and actual slight solid oedema of the skin of this arm, which were present from the onset of the disease, still return from time to time.

I may mention that this was the first occasion on which I had been treated with serum.

Fatal Anuria following Sulphapyridine in Pneumonia

The admission to No. 4 General Hospital, B.E.F., of the case described below occurred shortly before the hurried evacuation of that unit from France, and it is regretted that as a consequence investigations were incomplete and records are deficient. It is felt nevertheless that, in view of its rather unusual nature, an account, however incomplete, may be of some value.

A necessarily brief review of the literature on the subject has produced few comparable cases of complete anuria following the administration of sulphapyridine, though the occurrence of haematuria seems to be not uncommon.

CASE RECORD

A lieutenant aged 42 was admitted to hospital on June 10, 940. He stated that, except for some bronchitis, he had been in good health until a few days previously, when during a train journey from the North of France he developed a pain in the right chest, not apparently severe at first. On the following day he had a severe pain in the right lumbar region lasting for fifteen minutes. On the day before admission the pain in the right chest recurred at frequent intervals, and was accompanied by shortness of breath. His temperature that evening was 100 F. On the morning of the day of admission his temperature was stated to be 99° F., he was short of breath, and he coughed up a small amount of blood-stained sputum.

On admission the patient's temperature was 100° F., the pulse 104, and respirations 24. He was a rather fat flabby man with ruddy complexion, not cyanosed and not very distressed, though respiration was slightly grunting. There were dullness, diminished air entry, and bronchial breathing at the right base behind; the lungs were otherwise clear. The pulse was full, bounding, and regular. It was apparently a case of lobar pneumonia. He was put on sulphapyridine at once—3 grammes at 6 p.m., 2 grammes at 10 p.m., and thereafter 1 gramme four-hourly. He was also ordered half an ounce of whisky every four hours as he admitted to a moderate consumption of alcohol, and his appearance corroborated this. On the following morning his general condition had improved and his temperature was normal, though there had been some vomiting. In the afternoon he complained of severe pain in the lumbar region and passed a small amount of heavily blood-stained urine. The administration of sulphapyridine was stopped at once, a total of 10 grammes having been given, but the loin pain necessitated morphine for its relief. He passed a poor night, but the next morning (June 12) he had no pain and his general condition was good. He had passed no more urine, but the bladder was not palpable. His blood pressure was 170/110 mm. Hg and his fundi showed no changes. Fluids were pushed and citrates administered. Passage of a catheter produced only a drachm of thick bloody urine.

On June 13 he developed pleural friction over the back and front of the right base and had still passed no urine. He had no headache, was mentally clear, and his general condition was still good. Fluids were still being pushed, and potassium citrate was increased to 40 grains every two hours. A hot pack was applied, resulting in profuse sweating, and during the night one pint of 4.2% sodium sulphate was given intravenously, without effect on urinary secretion.

On June 14 a few drops of bloody urine were passed containing a heavy crystalline deposit, which was proved to be composed of acetyl-sulphapyridine. His blood urea was then 155 mg. per 100 c.cm., and his condition was deteriorating. He was seen by Major-General R. Priest, Colonel Stott, and Colonel Max Page, and it was decided that decapsulation of the kidneys offered the only chance of survival.

The operation was performed by Lieut.-Colonel Porritt and Major D'Abreu. On exposure the kidneys were found to be enlarged, lobulated, and oedematous. No calculi were felt. The capsules stripped easily. The pelves were bluish in colour from the contained dark blood-stained grumous urine. A drainage tube was put into the pelvis of the right kidney. Small portions of each kidney were excised for section, but owing to the upheaval of the hurried evacuation it was not possible to complete the examination. The patient was returned to bed and a continuous intravenous drip-transfusion instituted. Practically no urine was passed from the pyelostomy tube, and death occurred at 10 p.m. on June 15.

CONCLUSIONS

In view of the failure of the pyelostomy to promote re-establishment of urinary secretion it is probable that the anuria was due to blockage of the renal tubules themselves and that the procedure of ureteral lavage, successfully carried out by Carroll *et al.* in a case of theirs, would have been useless at the stage at which operation was done. The total amount of sulphapyridine given was small, and the initial dose was no larger than in a number of other cases of pneumonia in which no urinary complications supervened. It is not clear what was the particular factor which induced the copious crystallization of the sulphapyridine in this case, but the unfortunate termination emphasizes the paramount importance of adequate fluid intake during the administration of sulphapyridine in all cases, especially when any suspicion of renal insufficiency exists. It is regrettable that a urine examination was not made on admission here.

Thanks are due to Major-General R. Priest, Colonel Stott, and Colonel Max Page for their most valuable advice, and to Lieut.-Colonel Porritt and Major D'Abreu for their surgical co-operation. I wish also to thank Colonel D. G. Harding, O.C., No. 4 General Hospital, B.E.F., for permission to present this article for publication.

Resistance to Disease by Dietary

"In young children it is logical to supplement a diet suspected of being deficient by the addition of Vitamin D and calcium salts and even to prescribe these in proper dosage for any child with the hope .... of improving the structure of the teeth to such an extent as to give them a higher resistance to disease."

("Lancet" Editorial, July 16th, 1938, page 147).

There is an impressive weight of evidence, that our dietary does not always contain the optimum amounts of calcium required for normal health, especially in the cases of expectant and nursing mothers and during the years of growing childhood and adolescence.

Calcilac has been prepared to fulfil the essentials of palatability, solubility and food. A pleasant full-cream chocolate-flavoured milk, it contains easily assimilable calcium salts (as gluconate) and natural vitamins A and D.

Calcilac is indicated as a supplementary food in the dietary of children for the prevention of dental caries and for all cases of calcium deficiency, e.g., chilblains, brittle finger-nails, rickets.

A COW & GATE PRODUCT

Milton treatment of wounds

This treatment proceeds by three stages:–

1. MILTON 50% DILUTION

Thorough cleansing and mechanical removal of all infected plasma proteids, necrotic tissue and pus. Milton dissolves this detritus and rapidly sterilises the clean surface. As a hypertonic saline it produces profuse fluid exudation.

> *"The process of mechanical cleansing is of "most advantage in wounds containing sloughs "and is well served by solutions containing "chlorine or liberating oxygen, both of which "tend to disintegrate and detach necrotic "tissue."*—*Lancet, May* 4, 1940.*
>
> *"The most rapidly acting antiseptics are the "halogens and those liberating nascent oxygen."* —*Lancet, April* 27, 1940.*
>
> *"Profuse fluid exudation can be deliberately "produced by applying hypertonic solutions "of salt."*—*Lancet, May* 4, 1940.*

2. MILTON 5% DILUTION

The clean wound is kept sterile by an isotonic antiseptic protective layer, applied by dressing, irrigation or immersion. In this mild aqueous medium a normal granulation proceeds.

> *"The proper vehicle for an antiseptic to be "applied to a wound is water, and the solution "should if possible be rendered isotonic."*— *Lancet, May* 4, 1940.*

3. MILTON ½% DILUTION

The Milton is then reduced to ½ per cent. at which dilution the hypochlorite has been found to actually stimulate cell-division and tissue-growth, with consequent rapid healing.

After débridement, this course of treatment is normally painless.

This therapy cannot be carried out with full success by the use of Dakin's solution or of Liq. Sod. Chlorin., owing to their causticity, their deficient saline content and to their varying strength of hypochlorite.

* *Prevention and Treatment of Wound Infection.*
Action of Antiseptics on Wounds.

Milton the stable sodium hypochlorite

non-irritant and of standard strength

Reviews

TREATMENT OF CANCER

Treatment of Cancer and Allied Diseases. Edited by George T. Pack, B.Sc., M.D., F.A.C.S., and Edward M. Livingston, B.Sc., M.D. In three volumes. ($36.00 or £9 the set.) New York and London: Paul B. Hoeber, Inc., Medical Book Department of Harper and Brothers.

To describe the treatment of cancer and allied conditions in all its various aspects and in all parts of the body is a task which really merits the use of that overworked adjective "colossal"; nevertheless it has been attempted and carried through in a praiseworthy manner in the books now under review. It is not surprising, therefore, to find that the three large volumes contain some 2,600 pages of matter, while the indexes alone add more than 200 pages to this total.

The general editorship is in the hands of George T. Pack and Edward M. Livingston, and the list of contributors contains 150 names of authors, many of them with international reputations. From such a galaxy we can only pick upon a few for mention, but the following names carry their own significance: Adson, Balfour, Braasch, Broders, Chaoul, Coley, Crile, Ewing, Gwathmey, Handley, Jackson, Lahey, Mayo, Polya, Rankin, Young; yet the other names in this long list are scarcely less imposing. A high general standard of information would naturally be expected from such sources, and a perusal of the various sections shows that our anticipations are justified. It is obviously impossible in a short review to examine each section critically, but mention can be made of a few to indicate the character of the work.

An early chapter on the microscopical grading of cancer affords an excellent opportunity for Broders to explain his investigations on this subject; others on surgical, aspiration, and punch biopsy are full of practical information. Several good chapters are devoted to the general theory and application of radiation therapy in all its forms, including the Chaoul tube on the one hand and the use of very high voltage installations on the other. Quite properly the question of protection in radiotherapy receives adequate attention. Following these discursive sections the rest of the book deals regionally with cancer of the various organs. In each section the description of treatment is comprehensive, and includes surgery, diathermy, irradiation in all its forms, and, where appropriate, other forms of treatment such as Coley's fluid, etc. Even such matters as the prosthetic reconstruction of the face and mouth following cancer therapy are not neglected.

On the whole it seems that the balance between the various methods of attacking cancer in any particular situation is well held, and in the few instances where the authors' opinions do not agree, as is bound to occur in a book of this type, the editors have added some judicial paragraphs to guide the reader. The combined knowledge and skill here represented could not possibly come within the range of one man's ability, but the multiple authorship occasionally leads, despite efficient editing, to a certain amount of overlap. In particular this is noted in the sections on growths of the colon and rectum. There are some 1,500 illustrations, the high quality of which is equalled by the general make-up of the volumes. The publishers as well as the authors are to be congratulated upon their enterprise in producing a notable contribution to the cancer problem, and, provided the matter can from time to time be brought up to date, these volumes should be universally recognized as a standard of reference in this subject for a long period to come.

HANDBOOK OF ANAESTHETICS

Handbook of Anaesthetics. (Formerly Ross and Fairlie.) Fifth edition. Revised by R. J. Minnitt, M.D., D.A. With Chapters on Local and Spinal Anaesthesia by W. Quarry Wood, M.D., Ch.M., F.R.C.S.Ed. (Pp. 364; illustrated. 12s. 6d. net, postage 7d.) Edinburgh: E. and S. Livingstone. 1940.

In his preface to the fifth edition of Ross and Fairlie's *Handbook of Anaesthetics* Dr. R. J. Minnitt drops a broad hint that he means to do a good deal of sweeping before the sixth edition appears but is rather acutely conscious of being a new broom this time. His difficulty is one with which it is easy to sympathize: for he has to bring up to date an elementary textbook (usually more difficult to write than an advanced one) which has achieved a recognized position through the possession of several real and obvious merits. Among these were clear presentation of accurate information, good selection of what must be included and what omitted in a book of limited scope, and good arrangement of material. In the present evidently transitional stage of development it would be better not to offer criticism of things which Dr. Minnitt probably himself realizes are open to it, but to dwell rather on the substantial merits both of what he has inherited from his predecessors and what he has added to it.

Naturally some unevenness of style is observable: many chapters are almost models of well-expressed dogmatic teaching; others are rather full of grammatical solecisms such as "the patient is induced with . . ." (shade of Clifford Allbutt!) when what is meant is "anaesthesia is induced by . . ." The chapter on choice of anaesthetic for various types of case would gain by references to spinal and to local anaesthesia, which are virtually omitted from purview; and it may be suggested also that there are other causes of mechanical obstruction of the airway besides obstructive goitre, oedema of the glottis, and chest affections. Dr. Minnitt knows that well enough, of course, but students reading page 250 might not realize it. It is of no great intrinsic importance that novocain is not spelt with the final "e" which it is regularly given here, but this is a symptom of the rather perfunctory proof-reading which is doubtless on Dr. Minnitt's list of things to be remedied. The book is so valuable that it cannot be very long before "next time" comes about.

FOOD AND DIETETICS

Hutchison's Food and the Principles of Dietetics. Revised by V. H. Mottram, M.A., and George Graham, M.D., F.R.C.P. Ninth edition. (Pp. 648. 21s. net.) London: Edward Arnold and Co. 1940.

The ninth edition of Sir Robert Hutchison's "Food and the Principles of Dietetics" has been edited and extensively revised by Prof. Mottram and Dr. George Graham. Its contents fall into four parts. Part I deals with diet in normal life, and in the space of 184 pages an excellent account is given of the physiology of nutrition. Part II deals with the composition and character of food and beverages, and a vast amount of valuable information will be found in the 260 pages which comprise this section. No greater compliment can be given than to say that the section fully maintains the high standard which has made Hutchison's monograph one of the leading books on diet in this country for the past forty years. There next follows an excellent account of the principles of feeding in infancy and childhood by Dr. C. F. Harris.

The final section is mainly concerned with the dietetic treatment of disease. To the general practitioner this aspect is of particular importance, and he may well be disappointed that the editors should devote less than one-sixth of a book on dietetics to the part played by diet in the treatment of disease. Surely the value and the

limitations of diet in the various types and stages of the chronic rheumatic diseases and diseases of the heart and blood vessels and the liver and biliary tract are worthy of more space than the one or two pages devoted to them. This section does not reach the high standard attained by the rest of the book.

ACTIONS OF DRUGS

Pharmacology. By J. H. Gaddum, Sc.D., M.R.C.S., L.R.C.P. Oxford Medical Publications. (Pp. 407. 17s. 6d. net.) London: Oxford University Press. 1940.

Prof. Gaddum in the preface to his new textbook entitled *Pharmacology* explains that his object has been to present the general principles of the subject in a brief form to medical students. This task is one beset with great difficulties because pharmacology has developed along empirical lines, and in consequence an enormous mass of detailed information has been acquired, whilst general principles are scarce. Furthermore, the medical student is interested in a small number of compounds that have been chosen on account of their therapeutic value and not on account of their general pharmacological interest.

The volume comprises about 400 pages, and the author has dealt with all the chief drugs of therapeutic importance, hence his main problem has been that of selecting the most relevant data and presenting them as clearly and concisely as possible. The difficult problem of demonstrating the relations between different members of groups of compounds has been overcome by the use of ingenious tables which show the variations in structure very concisely and clearly. This method is applied to such groups as the sympathomimetic amines, the phenol derivatives, and the sulphonamide drugs. The volume covers all the important aspects of drug action, and certain sections provide information that is not readily available elsewhere in a concise form; such sections are those dealing with the action of drugs on nerve endings and the principles of biological assay.

The special interest of Prof. Gaddum's book is that it represents an approach to pharmacology from an unusual standpoint, and hence can be recommended not only to students but also to teachers of pharmacology and therapeutics.

CHILD PSYCHOLOGY FOR PROFESSIONAL WORKERS

Child Psychology for Professional Workers. By Florence M. Teagarden, Ph.D., Professor of Psychology, University of Pittsburgh. (Pp. 641. $3.25.) New York: Prentice-Hall, Inc.

Prof. Teagarden has produced a really valuable book. Primarily designed for professional social workers, teachers, and nurses who have to work among children, whether in school, home, or institution, this volume will prove to be a mine of information for anyone interested in the life of the child. Its great merit is that it is centred on the normal and not on the abnormal child, and that the author has succeded in avoiding the worst of the psychological jargon of the present day.

In a comprehensive study such as this much of the information is of necessity second-hand, and this is perhaps noticeable in the writing of the first few chapters, which deal with heredity, birth, and infantile development; but by the time the author reaches the chapters on the pre-school child and his progress through school life she has clearly come within the ambit of her own experience, and the book accordingly comes to life. The chapter in which behaviour difficulties are surveyed is especially good, while those chapters concerned with the effects of various illnesses and sensory and physical defects are adequate if not detailed. Finally, a record of the children's charter as promulgated by President Hoover's White House Conference on Child Health and Protection is given: this might well be used as an ideal by all those concerned with the education of children in its widest sense. Although this book is meant primarily for a non-medical audience, doctors, in whatever branch of the profession they may find themselves, would do well to read it; for if we have any interest in our patients' welfare—which surely we must have—we all must come back to the proper upbringing of the child as the basis of healthy living.

Notes on Books

The latest of several recent popular books on medical microbiology is Dr. JOHN DREW'S *Man, Microbe, and Malady*, which has appeared in the sixpenny Pelican series. It is quite the most systematic and orthodox of its kind, and the inquiring and intelligent laymen will profit much by reading it. The arrangement and choice of subjects almost follow the lines of a regular textbook, but the author maintains interest by the use of simple language and by allowing facts to speak for themselves. The chapter on bacterial warfare is a novelty, and the reader will be relieved to hear that there are grave difficulties in the way of attacking effectively by this means. This is true, but there may be other methods which have not occurred to the author, and it would be rash to predict their failure in advance of any practical trial.

Occupational therapy has not received the attention in this country which it deserves. It is fairly well recognized in mental hospitals, and the few centres which teach it approach it chiefly from the point of view of psychiatry. It has, however, an invaluable scope in the after-treatment of nearly every form of disease. In the rebuilding of mind and spirit which is so necessary after most illnesses the lessons of the mental hospital can be usefully applied. In rehabilitation after orthopaedic injuries occupational therapy is a highly specialized art, for its application differs from limb to limb and even from case to case. Dr. NORAH A. HAWORTH and Miss E. MARY MACDONALD have written the first English textbook on the subject, which has for some years been fruitfully developed in Canada. Their *Theory of Occupational Therapy* (Baillière, Tindall and Cox; 6s.) is intended for students and nurses, and embodies a great deal of practical experience by well-known pioneers. They deal concisely with the treatment of mental patients, sufferers from tuberculosis and cardiac disease, and surgical and orthopaedic cases, and conclude with a practical chapter on finance, equipment, and the ancillary details of the art. The book is copiously illustrated with photographs and line drawings.

Preparations and Appliances

REFINED TETANUS AND GAS-GANGRENE ANTITOXIN-GLOBULINS

Mixed tetanus and gas-gangrene antitoxin is issued for the convenience of those who are called upon to treat wounds contaminated with soil, dust, etc., and is available as "Wellcome" brand refined tetanus and gas-gangrene polyvalent antitoxin-globulins. Each phial contains 3,000 international units of antitoxin for *Cl. tetani*, 3,000 units for *Cl. perfringens* (= *Cl. welchii*), 1,500 units for *Cl. septique*, and 1,000 units for *Cl. oedematiens*. These amounts are in accordance with the provisional recommendations of the Ministry of Health Emergency Medical Service for the serum prophylaxis of tetanus and gas gangrene (*British Medical Journal*, 1939, **2**, *Supplement*, p. 169). The entire contents of the phial may be injected subcutaneously or intramuscularly as soon as possible after receipt of a wound that may have been infected with pathogenic anaerobes.

SATURDAY FEBRUARY 15 1941

TRICHINIASIS IN ENGLAND NOW

Following our editorial warning last week (p. 202) that trichiniasis exists in this country, we publish this week at page 237 an account by J. E. S. Lee of the disease as seen at the present time in Wolverhampton. A description by J. H. Sheldon of the same outbreak appears in the current issue of the *Lancet*. Suspicious cases were first seen in the middle of December last, and soon afterwards some of the more severe were admitted to hospital. The nature of what was evidently a distinct and unfamiliar disease entity was finally determined by the demonstration of *Trichinella spiralis* embryos in a piece of excised muscle. Some 500 cases have occurred in this district, and, although some of them have been severe, there have fortunately been no deaths. The clinical picture departs from the usual description in several ways. During the first week after consuming infected meat vomiting, diarrhoea, and upper abdominal pain are said to be characteristic: in these cases they were often completely absent; according to Sheldon only 10% had vomiting and 5% diarrhoea, the majority being constipated, sometimes severely. The absence of prodromal gastro-intestinal disturbance is therefore not a point against the diagnosis, and symptomatic recognition must depend mainly on the features of the stage of invasion. The first of these is usually swelling of the eyelids, accompanied by severe frontal headache; a few days later involvement of the skeletal muscles usually causes pain, tenderness, and stiffness. These effects are very variable, ranging from complete absence in slight cases to a condition said to be worse than labour pains, and causing such stiffness that patients have said they "might have been plaster statues"; the duration of muscular symptoms also varies from a few days to five weeks. A prominent and unusual feature in this epidemic has been evidence of involvement of the nervous system, and this of several kinds. Some cases present the picture of meningitis, with head retraction, semiconsciousness, irritability, photophobia, a meningeal cry, a positive Kernig sign, and extensor plantar responses. Others are deeply lethargic, depressed, and even deluded. Finally, no fewer than thirteen out of seventy-six cases (17%) described by Sheldon have presented signs of focal cerebral lesions, in the form either of monoplegia or of ataxia. Not only may these nervous manifestations complicate a severe and otherwise typical case, but in some giddiness, weakness, and ataxia have been the first manifestations, even preceding the swollen eyes. The general picture is therefore highly complex, and consideration of trichiniasis may be necessary in the differential diagnosis of a large variety of conditions. Fortunately the true nature of the disease seems to be invariably betrayed within the first few days if not at the very onset by oedema of the eyelids—an absolutely constant sign which in the absence of albuminuria calls for a differential leucocyte count; a marked eosinophilia almost certainly establishes the diagnosis. This blood change may apparently develop late, and was equivocal in degree in some of the cases described by Lee. It would be useful to do repeated counts on a series of cases diagnosed early in order to define more exactly what blood picture is to be expected at each stage. Of the various methods of positive diagnosis by demonstration of the parasite, according to D. L. Augustine,[1] concentration of the blood for embryos and searching the stools for adult worms so often yield no result as to be a waste of time; muscle biopsy may also fail to reveal embryos in a lightly infested case. This author recommends the use of an antigen prepared from embryos both for a skin sensitivity test, which becomes positive during the second week, and a serum precipitin test, first applicable during the fourth week. Since both these reactions persist for a year or more they would serve admirably for ascertaining the full extent of an epidemic during its later stages or even after it is over, as well as for confirming the diagnosis in individual cases. An improved method for preparing the antigen has recently been described by J. Bozicevich.[2]

We also publish a short account by L. P. Garrod and D. MacLean of further cases of trichiniasis which have been diagnosed in Hertfordshire since the existence of the disease in this country became known. This minor but significant incident perhaps illustrates the consequences which may accrue to the public health if E.M.S. laboratories are looked upon not merely as sources of reports on specimens but as consultative centres for epidemiological problems. The extent of the disease in this area is not yet known, but five comparatively mild cases have so far been diagnosed, each presenting a typical clinical picture and having an eosinophil count of over 2,000 per c.mm.: the embryo has been found in muscle from one case. The importance of these few cases lies of course in the fact that they appear unlikely to be connected in any way with the Wolverhampton outbreak, and the recognition of the disease in another area raises the possibility that it may be widespread. It is incumbent on practitioners throughout the country to be on the look-out for cases having these features, and to call in laboratory aid whenever the disease may be suspected.

Until the extent of the disease is fully known it cannot too strongly be urged that all pork and pork products should everywhere be thoroughly cooked. Sausages are chiefly suspect, and it does not seem to be generally known that the meat they contain has usually not been cooked at all, nor are all physicians perhaps aware that eating raw sausage is a common habit. The piece of social research in this connexion described by Sheldon produced astonishing results. As soon as this habit was recognized as a factor in the Wolverhampton outbreak, all patients were asked about it, and of the next fifty-nine seen thirty-seven confessed to it. It was also found to explain the peculiar sex incidence: sixty-two of Sheldon's patients were females and only fourteen males. Apparently working-class women content themselves with raw sausage either because it is a tasty and portable lunch to take to a

factory, or, if they are married, because housework leaves them no time or inclination to prepare a proper meal; their husbands, on the other hand, expect things to be cooked for them. A warning against the dangerous practice of eating raw sausage should be sounded throughout the length and breadth of the land.

OVERHAULING ASEPTIC TECHNIQUE

At a congress of the American College of Surgeons held in October, 1939, the proceedings of which have only recently been reported,[1] post-operative infections and the measures by which they can be prevented were discussed from almost every possible point of view. The mere fact that this subject was chosen for so prolonged a debate acknowledges that perfection in aseptic technique has not been generally reached; what was said on some aspects of it suggests rather there is much room for improvement. This report forms an interesting corollary to the paper by Prof. A. A. Miles and his colleagues which we published a few weeks ago,[2] for both deal with different aspects of the same subject. The study initiated by the War Wounds Committee of the Medical Research Council has developed on lines which have shown that much preventable infection in wounds is due to imperfections in ward technique; it is suggested that if precautions usually taken in operating theatres were also observed in ward work the transmission of infection could be prevented. The American report, on the other hand, deals almost exclusively with theatre technique itself—that aspect of surgery which should be a model for all other proceedings undertaken in its name. Let us grant at once that theatre infections are far less common than those acquired in septic wards; the problem is not of the same magnitude. But what it does amount to can only be ascertained by accurate record-keeping, and when such a system was introduced in 1925 at the Presbyterian Hospital, New York, it was found that the frequency of post-operative wound infections was no less than 14% of all cases, 4% being serious and 10% trivial. These records have been carefully kept since then; cases have been reported weekly to the staff conference, and changes made in aseptic technique to eliminate the apparent source of infection. The incidence of infections has declined steadily, and amounted in 1939 to only 0.6% classified as serious and 2.6% as trivial.

Among measures for minimizing contamination of the wound the first recommendation made at this congress was the use of an efficient mask, which is now well known to mean one containing an impermeable layer of some such material as cellophane. Current American opinion that the air is the source of staphylococcal wound infection is reflected in several communications on the use of ultra-violet light for air sterilization; but glove perforations are not forgotten, and it is recommended both that small punctures should be more carefully looked for and that a record be kept of the numbers produced by each surgeon, with a view to persuading the chief sinners to take greater care. The patient's own skin is another possible source of wound infection, and pre-operative skin disinfection comes in for discussion here; but the recommendations made are simple and would lead no uninstructed reader to suppose that methods favoured for this purpose are legion. It is laid down that preliminary cleansing with liquid soap followed by ether and alcohol and the application of a sterile dressing should take place in the ward; for the further swabbing with ether and alcohol carried out in the theatre before the application of a mercurial or dye antiseptic minute directions are given for wiping towards the periphery in order not to transfer bacteria from the unsterile edge of the operative area to the line of incision in its centre. How important such details may be must be left to individual judgment, but it scarcely needs to be said that nothing like this amount of care is always taken over this proceeding.

"Supposedly sterile materials" are the final source of danger dealt with at this congress. Catgut, of course, has always been a problem, but the absolute and invariable sterility of instruments and of fabrics such as towels and dressings is a fundamental condition of successful surgery. It is usually assumed with confidence. Is this confidence always justified? The most detailed report in these proceedings deals with steam disinfection: it condemns the use of metal drums, and condemns the vacuum displacement of air, thereby classing as potentially inefficient probably nine-tenths of steam sterilization in theatre practice in this country. Gravity air clearance, a horizontal path for air escape, and a thermometer at the outlet which must read 250° F. before sterilization is considered to have begun are laid down as essentials. The sterilization of instruments is the subject of a paper which begins by recording the answers to a questionary on this subject sent to 207 leading hospitals in all parts of the U.S.A., producing 106 replies. The variety of practice revealed in these replies is astonishing. No fewer than sixteen different methods are used, with variations. Boiling for various periods in either water or a solution of soda and autoclaving at various pressures (temperature not being mentioned) are the most popular. Other methods of applying heat are immersion in oil at 250° F. and a hot-air oven at 170° C., which have ten advocates and one respectively. Alcohol alone in concentrations of from 50 to 95% is used at six institutions, and lysol or carbolic acid in various strengths or combinations with glycerol or alcohol in about twenty others; biniodide of mercury and "70% alcohol and soda soap" have only one advocate each. It should be understood that these are methods used for simple steel instruments: had the inquiry embraced catheters, rubber articles, and suture materials the variety of replies would no doubt have been greater. The author of this paper, E. E. Ecker, goes on to discuss a large variety of other chemical reagents which have been recommended for instrument sterilization, and seems concerned rather to deplore this lack of uniformity in practice than to advocate any particular method, although his statement that boiling in a 2% solution of soda will sterilize a soil suspension in five minutes implies that here is one answer to the problem. There is, of course, no harm in using whatever method one fancies provided that it works, but some of these do not.

[1] *Surg. Gynec. Obstet.*, 1940, 71, 403.
[2] *British Medical Journal*, 1940, 2, 855.

Ecker expresses the hope that the college whose members he is addressing will officially adopt standard methods for this purpose. There is much to be said for authoritative pronouncement on matters of this kind, based if necessary on a reinvestigation of the methods in use, taking account first and foremost of their dependability, but, having assured that, also of their convenience and cost. To define the best methods of sterilizing all surgical apparatus in general use would be to sweep away a vast mass of varied ritual which, apart from its merits or defects, is a burden and a source of confusion to the nurses who have to carry it out. This is no new subject: the pitfalls of steam disinfection, the inefficiency of alcohol, and the limitations of formaldehyde, for example, have all been discussed in this *Journal* in recent times, as have the new problems in sterilization constantly presented by the ever-increasing complexity of surgical apparatus and the variety of materials used. It is not too much to say that a general overhaul of aseptic technique would benefit everyone concerned.

CROSS-INFECTION IN WARDS

Hospital infections, once a terrifying scourge, are not now as common or dangerous as until nearly the end of last century, but if we have flattered ourselves that they no longer happen studies made during the past few years should have disabused us. Everyone knows that a second disease may occasionally be acquired in a fever hospital, but what we have learned lately concerns the wards of general hospitals and varied types of infection the spread of which can only be traced by detailed bacteriological study. The work of Okell and Elliott on cross-infection by haemolytic streptococci in ear, nose, and throat wards first established this method of study; another example of its application is to be found in the recent paper by A. A. Miles[1] and others on the hospital infection of war wounds. A systematic study by this method in the hospital of its origin is also described by Joyce Wright[2]: this was carried out in the children's wards at University College Hospital, covered a period of one year, and was designed to trace the migrations of haemolytic streptococci. All patients had throat swabs taken on admission and at intervals of a week thereafter; nurses' throats were also swabbed weekly, as were any septic or other lesions as they arose which were likely to be streptococcal. The Griffith type of all streptococci was determined, a proceeding to which this sort of detective work owes almost the whole of its value; but for the almost certain proof of identity between strains which can thus be secured the interpretation of such studies would be mere guesswork. Of a total of 551 cases thirty-six had haemolytic streptococci in their throats on admission; seventy-two (13,1%) acquired a haemolytic streptococcal infection of some kind during their stay in hospital. Most of these individual cases formed items in well-defined outbreaks, some having the dimensions of an epidemic, each due to a single type of streptococcus. Each of these outbreaks comprised a variety of clinical conditions—sore throats, otitis media, wound infections—as well as latent cases in which the organism existed in the throat without producing evident effects. That they were recognized as outbreaks having a single cause was due to their analysis in the laboratory: otherwise the overt cases would doubtless have been accepted as misfortunes in the general run of common experience, while the latent infections would of course have been unrecognized. The exact method of spread was not determined; cubicle isolation prevented it, but whether any measure short of this will be effective remains to be decided. A somewhat similar study has been made by H. D. Wright, H. R. Shone, and J. R. Tucker[3] in diphtheria wards. Here proof of cross-infection depends on the existence of *gravis, intermedius,* and *mitis* types of *C. diphtheriae* and the demonstration that a change of type has occurred in the individual throat: this method, of course, cannot reveal all cases of cross-infection, since the newly acquired infection may be of the same type as that existing before. Nevertheless in over 10% of cases in ordinary diphtheria wards reinfection was proved by this means; where bed isolation was practised it occurred in about 5%, while in cubicle wards it rarely occurred at all. Here again the mode of spread is uncertain; contact between patients and carriers among the staff are possible factors, but the most suspicious finding was the presence of fully virulent diphtheria bacilli, often in large numbers, in floor dust, coupled with the fact that old-fashioned methods of sweeping were employed. It is becoming abundantly clear that the oil treatment of floors recommended by Van den Ende and others,[4] possibly extended as they suggest to blankets, is the first necessity in preventing hospital infections caused by diphtheria bacilli and haemolytic streptococci. Only when this wide-open avenue of spread has been closed, as far as feasible precautions can close it, shall we be able to decide what other channels of infection remain to be stopped.

BISMUTH IN SYPHILIS

Since the introduction of bismuth as a therapeutic agent in the treatment of syphilis there has been much speculation and discussion concerning its mode of action and the dosage and toxicity of the numerous preparations employed. Kolmer and his associates[5 6] concluded from some experiments in rabbits that toxicity did not necessarily run *pari passu* with the amount of bismuth metal injected; that toxicity and therapeutic effectiveness vary according to solubility, not only in the tissues but in the vehicle, and to rate of absorption and excretion; and that both factors are influenced by chemical constitution. Further, as estimations of bismuth in the blood are not a practicable way of determining maximum therapeutic effectiveness consistent with minimum toxicity, recourse was had to urine estimations. It was found that in the case of infected rabbits the urinary level of bismuth required for biological cure was dependent on both the dose and the length of time it was maintained; a certain minimum level is required even though there is prolonged excretion. Human beings require relatively more metal per kilogramme of body weight than rabbits, and it has been calculated that for optimum therapeutic results the amount of bismuth should be 35 to 45 mg. per dose, which would give a urinary excretion of 2 to 4 mg. The amount of any particular preparation injected and the frequency with which it is given will depend on whether the preparation is water-soluble, oil-soluble, or insoluble, and since absorption of the drug varies not only according to the compound but also in relation to the individual himself occasional determinations of urinary bismuth are recommended. Experiments carried out on spirochaetes prove that bismuth is spirochaeticidal both *in vivo* and *in vitro*. Whether this is due to the element itself dissociated from its compounds or whether it effects a union with

[3] *J. Path. Bact.* 1941, 52, 111.

[6] Ibid., 459.

the tissues is not established. The latter appears to be more likely, but the metal may act in part by the stimulation of antibody production which results from the release of antigenic substances from killed spirochaetes. As a result of their experiments the authors give a list of recommended doses of eleven different bismuth preparations commonly used in America: water-soluble preparations should be given twice weekly, others once every seven to ten days. Bismuth has also a prophylactic action in syphilis, as shown by the experiments of Kolle,[7] who failed to infect rabbits so long as there was any of the metal in the ear, and by Sonnenberg,[8] who was able to protect prostitutes from acquiring the disease by regular intramuscular injections of the subnitrate. These methods, however, are not a practical proposition for mass prophylaxis of human beings. Hanzlik and his co-workers[9] found that when sobisminol, a preparation which has a curative action when taken by the mouth, was given to rabbits it protected them against experimental infection. In view of the fact that the drug, although comparatively non-toxic, has a curative action in human syphilis, it is suggested that it could be used for human prophylaxis with much hope of success. Although this appears to be theoretically probable, it has not yet been tried out, and the average man will hardly dose himself for a week before exposing himself to possible infection, and after exposure the drug is not likely to prove successful, since the spirochaetes will have established themselves before the bismuth has reached an adequate concentration in the tissues.

PERITONEAL IRRITATION AND INTESTINAL ACTIVITY

The surgeon is constantly confronted by the problem of the management of abdominal distension resulting from peritonitis. The causation of this distension has immediate bearings upon the question of treatment. In the absence of gross obstruction associated with colic, a "mechanical" view must favour operative treatment. On the other hand, if the distension is regarded as neurogenic and due to reflex inhibition resulting from peritoneal irritation, then the treatment must be on conservative lines. From the point of view of management the important case is the one in which there is abdominal distension in the absence of all intestinal activity. In the current number of the *Journal*, Douglas and Mann report a series of interesting experiments which shed a good deal of light on the pathological physiology of the condition. These workers produced exteriorized portions of intestine in rabbits and dogs after the method introduced by Biebl. The exteriorized loop remains in continuity with the bowel, has an intact nerve and blood supply, and is enclosed in a bipedicled skin tube completely shut off from the general peritoneal cavity. Subsequently various irritants were injected into the general peritoneal cavity and observations recorded on the activity of the exteriorized gut segment. For the purpose of these experiments inhibition was considered to mean absolute quiescence of the intestine. In the control series of cases it was shown that the injection of Ringer-Locke solution into the general peritoneal cavity produced an effect on intestinal motility. When standardized irritants were injected these constantly led to prolonged arrest of intestinal movements in the exteriorized segment. This arrest occurred in normal animals after section of both vagus nerves, after section of one splanchnic nerve, and after bilateral adrenalectomy. On the other hand, this inhibition did not occur, or was only temporary, after degenerative section of both splanchnic nerves. On the basis of these experiments the authors conclude that intestinal inactivity is of the nature of reflex inhibition, since by reason of the extraperitoneal situation of the loop of bowel the stimulus is delivered to afferents other than those in the loop. The authors hesitate to apply their experimental results too directly to clinical work, but suggest that their evidence supports the neurogenic explanation of abdominal distension associated with a localized peritonitis. Under these conditions operative treatment by means of enterostomy, etc., is contraindicated, and measures designed to overcome the splanchnic inhibition are indicated—namely, splanchnic block, acetylcholine, or prostigmin.

WARTIME RESEARCHES ON MILK

In war the dairy cow takes rank as "Farm Animal No. 1." Milk, a home-produced food obtained from animals deriving more than 80% of their food requirements from home-grown feeding stuffs, is a means of supplementing and balancing a diet which might easily become in wartime poor in everything except carbohydrates and calories. The shadow of war is cast upon the annual reports of two dairy research institutes lately received, though one of them, that of the National Institute for Research in Dairying, Reading, is for the year ending September, 1939, and the other, that of the Hannah Dairy Research Institute, Ayr, is for the year ending March, 1940. In both institutes the maintenance of as high an output of milk as possible in emergency conditions has become the keynote of the work, and long-range investigations have receded into the background in favour of the quicker but less satisfactory methods of empirical investigation and piecemeal solution. Among other matters with which the National Institute has concerned itself is wartime cheesemaking. Rennet, which is used to make milk coagulate, is an animal product, an extract of a calf's stomach, but a satisfactory method for extraction of a milk-coagulating enzyme from a vegetable source has been found, and cheese for which vegetable rennet was used has recently been produced. Much further work has been done at Reading on the estimation of vitamins in milk. Biological methods had already shown that commercial pasteurization brought about a definite though small loss in the vitamin B complex, and that commercial sterilization destroyed some 30% of vitamin B_1 but had no apparent adverse effect on vitamin B_2. These findings have now been extended by the application of chemical tests, according to which pasteurization destroys 10% of vitamin B_1 but is without effect on riboflavin, while the loss of B_1 in sterilized milk has been found to amount to 50%, riboflavin again being unaffected. In view of the errors of biological assay, the measure of agreement between the findings obtained by the two methods is regarded as satisfactory. Another piece of research concerns the effect of light on the vitamin C of milk in containers. Visible light is known to have a destructive effect on this vitamin, and experiments have been carried out with bottles of different colours. Brown glass bottles have been found to be most effective from the point of view of preserving the vitamin; green glass bottles come next, and then wax-impregnated cartons. In the cartons twice as much of the vitamin survives as in clear glass bottles. Work has also been done at Reading on the physiology of bovine lactation. Repeated injections of ox anterior pituitary extracts rich respectively in prolactin (pigeon crop-gland stimulating factor) and thyrotrophic hormone into cows in declining lactation have resulted in a marked increase in milk yield, and, with the prolactin

preparation, in a substantial increase in fat content, the average daily milk-fat production being raised by nearly 50%. The milk yield does not continue to increase throughout the period of prolactin treatment, but reaches a steady level and then declines. It is considered that the increase in milk yield and milk-fat content following injections of pituitary extracts cannot be ascribed to the action of a single hormone; probably the secretion of milk-fat is a mechanism distinct from those governing the secretion of other milk constituents. The Hannah Institute has also been occupied with lactation studies, especially the problem of inheritance of persistency of milk yield, or the extent to which ability to maintain a level yield is transmitted by the parent. The experimental results demonstrate the important part played by environment in determining the shape of the lactation curve. It seems likely that a uniform method of bacteriological examination of milk may be adopted for Great Britain. Hitherto in England and Wales the methylene-blue reduction test has been used, and in Scotland the plate count. One reason why the former method has not been adopted in Scotland is that it is said to be less reliable when applied to milk produced and handled in a colder climate. The convenience of the methylene-blue reduction test and its simplicity and cheapness in comparison with the plate count have seemed to justify a more detailed examination of the effect of temperature on its reliability, and so far as the work has gone the temperature factor does not appear to be an insuperable obstacle to the adoption of the reduction method under Scottish climatic conditions.

U.S. HEALTH UNIT AND LIAISON OFFICER

With the consent of the President of Harvard University, Dr. J. E. Gordon, who holds the Charles Wilder Chair of Preventive Medicine and Epidemiology at Harvard, has accepted Mr. Malcolm MacDonald's invitation to act as United States Liaison Officer with the Ministry of Health. Shortly after the outbreak of war Harvard University appointed a committee to consider how the university could contribute material or professional help to a cause closely concerned with its interests. The possible nature of this help was conceived in the broadest terms, with the suggestion that it might be in economics, medicine, sociology, public health, law, and perhaps other fields. Through an exchange of opinion between authorities of Harvard and colleagues in Great Britain it later became evident that help in the fields of public health and medicine was most clearly in point. As a consequence Harvard University made a formal offer to the Minister of Health, which Mr. MacDonald gratefully accepted, to equip and maintain in Great Britain a public health unit for the study and control of communicable disease. The purposes of the unit were defined as: (1) to lend material aid to a friendly nation; (2) to investigate communicable disease under unusual military and civil conditions; (3) to obtain medical information of value to the national defence of America. The unit as originally conceived was to include a group of workers concerned with field studies in epidemiology and a laboratory for the study of associated problems. British authorities early pointed out the desirability of adding to this basic unit a well-equipped hospital for the clinical care and study of communicable disease. This addition became possible through the active co-operation of the American Red Cross, who agreed to build and transport to Great Britain a hospital of 125 beds. The final plans for the unit evolved from discussions between Prof. Gordon and the authorities of the Ministry of Health in London during August and September. Facilities and staff are provided for the study of communicable disease in the field, in the laboratory, and at the bedside. Prof. Gordon returned to America in the latter part of September to assemble staff, order equipment, and lay plans for the hospital. He left in London Dr. John R. Mote, assistant in epidemiology in the Department of Preventive Medicine, Harvard University, now acting as medical adviser to the American Red Cross Committee in London, to continue and complete local arrangements. Prof. Gordon has now returned here, and the first shipments of buildings and equipment are expected to arrive shortly. The headquarters of the unit will be in south-west England, with provision for a mobile team to serve more widely as need may arise. As U.S. Liaison Officer with the Ministry of Health, Prof. Gordon has an office in the Ministry, and is taken freely into the confidence of the Minister and the staff of the Department.

THE KING'S ENGLISH

The latest protest against defilements of "our maternall Englysshe tongue" comes, not from Mr. A. P. Herbert, but from another member of the House of Commons, Mr. Henry Strauss, who in a recent letter to the *Times* denounces as a neologism the word "hospitalize," importing to send a person to a hospital, or to admit or to maintain someone there. Most of us will thank Mr. Strauss for his protest against a horrible word of very ambiguous meaning; but even so it may perhaps not lack defenders, for it raises the old issue between the precisians, whom their critics call pedantic, and the colloquialists, whom the "highbrows" dub illiterate. Language, say the latter, must grow; must adopt new words for new conceptions; must throw off the shackles of obsolete convention under pain of becoming not a living but a dead tongue. They note that sometimes the slang of one generation becomes accepted usage, even of the scholar, in the next or the next but one; and if their sentences lack a verb here or grammatical structure there, comfort themselves with the reflection that anyhow people know what they mean, which is not invariably true. So many of us fall into slipshod speech ourselves that these excuses often gain acceptance among those who dislike to label themselves self-righteous. For all that, slipshod speech and writing are merely signs of slipshod thought and downright muddle. The danger is especially to be avoided in scientific writings, where the exact meaning of every word and phrase should be crystal clear and incapable of misconstruction; if medicine is to remain a science it must conform to this standard. English is not an easy language, but every shade of meaning can be accurately expressed in it if sufficient trouble is taken. Many of us, for instance, are too prone to "give a case morphine," when it is the patient, not the case, who receives the drug; or to say the patient "has no temperature," meaning no rise of temperature; or to "operate a tracheotomy" (an Americanism which shows signs of acclimatization here) instead of to perform it. "Reconsider" is another word which gives rise to trouble: its proper meaning is to consider anew: but some people now use it as equivalent to altering a previous resolution, from which the awkward dilemma arises (if this latter usage stands) that one can reconsider a decision without reconsidering it. And if any reader should detect a deplorable solecism in the columns of the *Journal*, all the Editor can say in mitigation is that he will reconsider the matter.

The Right Hon. Malcolm MacDonald, M.P., has been chosen to fill the post of High Commissioner in Canada for His Majesty's Government in the United Kingdom, and is succeeded as Minister of Health by Mr. Ernest Brown, lately Secretary of State for Scotland.

MEDICAL ASPECTS OF A.R.P.

A conference summoned by the Association of Architects, Surveyors, and Technical Assistants and the National A.R.P. Co-ordinating Committee (the body of which Prof. J. B. S. Haldane is chairman) was held at Islington on February 2. It was attended chiefly by members of London local authorities and their medical officers of health and borough engineers, and the full day's discussion ranged generally over the safety and health aspects of the shelter problem.

An introductory statement was made by Mr. P. P. ROSENFELD, a prominent member of both the convening bodies, who declared the surface shelters to be never more than half occupied, basement shelters commanding greater public confidence. He put the case for what is popularly known as the Haldane shelter (though Prof. Haldane makes no claim to be its designer), which is planned in two stages, the first stage giving as high a standard of health and amenity as is immediately practicable, and the second affording opportunity for strengthening and extending to any degree desired as materials and labour become available. Present conditions in shelters—namely, overcrowding and bad ventilation, often combined with damp and cold—were favourable for the incubation and spread of disease. All previous standards of overcrowding control had gone by the board. In the large shelters also, insufficient and insanitary closets and contamination of food and water might lead to outbreaks of typhoid and dysentery, and typhus might arise from the dirty conditions which bred lice. The Chief Medical Officer of the Ministry of Health had stated that, apart from a certain increase in the incidence of enteric fever and cerebrospinal fever, there were no signs as yet of epidemics. But this, in Mr. Rosenfeld's view, gave little cause for satisfaction, because epidemics arose as a result of lowered standards of resistance coupled with such conditions as existed in many shelters, and once the ground was favourable epidemics might spread like a flame. He also criticized the insufficient height and faulty design of the bunks, the absence of ventilation plants in many shelters, and the instruction to local authorities to put in coal-burning stoves when electrical heaters would be preferable on all grounds.

Those responsible for calling that conference, he said, took the view that it was possible to provide shelters which were far safer than the present types and would furnish healthy conditions and reasonable comfort. The requirements to be fulfilled in a better shelter policy were: (1) a higher standard of protection against high explosives; (2) protection against gas attacks over long periods; (3) healthy conditions for sleeping, including some privacy, and proper spacing of bunks; (4) arrangements for seating; (5) proper sanitary arrangements, including washing facilities; (6) feeding arrangements, providing a limited number of hot meals for those who left straight for work, as well as hot drinks and snacks; (7) medical facilities and isolation arrangements; (8) ease of administration of shelters by marshals and local authorities.

Health Conditions in Shelters

Dr. JOAN MCMICHAEL, in introducing the medical aspects, said that the most important factor in the spread of epidemics was overcrowding, which in some shelters was present to an extreme degree. The possible sources of illness were many, including air-borne or droplet infections, infections due to direct contact, infections arising from defective sanitation aggravated by overcrowding, infections carried by animal pests (including mosquitos which bred in stagnant pools of water in some warm underground shelters), deficiency diseases, especially among Tube shelterers condemned for long periods to remoteness from air and sun, and finally the many hours in cramped positions might bring about an increase in the number of sudden deaths from pulmonary embolism. The Horder Report said that people should be encouraged to use the Anderson shelters, but it must be remembered that there was often severe overcrowding in these shelters, with far less warmth, comfort, and safety than in the public shelters. A good shelter programme should combine the maximum degree of safety with the minimum risk of disease. The two-stage shelter advocated by the A.R.P. Co-ordinating Committee was the best, because it left room for a certain amount of dispersal through the sections and was also to be approved from the medical point of view.

In the general discussion widespread dissatisfaction was expressed with the Government's shelter policy, and, particularly, with the failure to consult borough engineers and surveyors on problems relating to their own areas. Lack of co-operation between the Government and local authorities was evidently a sore point. Several representatives declared that they ought to be given more responsibility in their own localities and be less subject to the vagaries of Whitehall.

One speaker, a woman councillor, complained that doctors and nurses were being drafted into shelters rather with the idea of waiting for epidemics to turn up. Of course, in a large shelter many ailments besides epidemic illness call for attention. This speaker also mentioned the question of shelter sanitation and the "scandal of the bucket" on the Tube platform to be found at many stations. Water closets were still allowed only in certain cases. The compressors being fitted in Tubes to pump up the sewage would still necessitate the use of chemical closets, although they could have been arranged so as to be capable of taking water closets at a future date. An architect said that the installation of water closets would have been perfectly feasible; the initial cost would not have been much greater than that of the mechanical ejector system, and the cost of upkeep much smaller.

The conference also discussed the care of the bombed-out, and a plea was made for the appointment of officers in every borough whose task it would be to see that these people were dealt with rapidly and effectively, also for the keeping of registers of empty houses in which homeless persons could be placed immediately. A resolution was carried unanimously expressing disquiet at the effects of the Government policy in the London area, and urging much higher standards of safety, health, and welfare in the shelters, in particular the adoption of a design of shelter which would allow subsequent strengthening so as to render them proof at least against direct hits by bombs of medium calibre. The resolution also stressed the need for representation of local authorities in the offices of the Regional Commissioners.

AWARDS FOR GALLANTRY IN CIVIL DEFENCE

The award of the George Medal to Dr. Malcolm Manson, *M.C.*, Medical Officer of Health, Wood Green, is announced in a *Supplement* to the *London Gazette* dated February 7, and in the same issue the names of Dr. John Spittal Cameron, assistant medical officer, Emergency Medical Service, Fulham, and Dr. David Cochran Hanson, *M.C.*, medical officer of mobile unit, Emergency Medical Service, Fulham, are included in a list of those who have received commendations for brave conduct in civil defence.

Dr. MALCOLM MANSON: "A heavy H.E. bomb fell, causing a tunnel to collapse. A number of people were trapped under the debris and the clay which had fallen through the cavity. Dr. Manson arrived on the scene within a few minutes of the occurrence, and immediately assumed the direction and leadership of the rescue work. For nearly three hours he worked without intermission actively participating in the release of persons trapped in the debris heap, giving medical aid where it was needed and all the time keeping effective control. Throughout this period he was in grave personal danger from frequent falls of clay. It seemed likely that a further portion of the tunnel would collapse. At one period he was lying full length on the heap endeavouring to release a man partially buried when there was a shout from the look-out man of 'Run for it.' The doctor ignored the warning and continued his efforts for the trapped man. There was a large fall of clay and the doctor was struck by a large piece full in the back. He was partially buried and had to be dragged out feet foremost. He rested for a few minutes, and then, in spite of severe pain, carried on with the work. Dr. Manson's pertinacity, courage, and disregard of personal safety set a wonderful example to the men and was no doubt responsible for the saving of a number of lives which otherwise would have been lost. He sustained serious injuries during the rescue operations."

To secure protective reserves

in ADOLESCENCE, PREGNANCY and DEBILITY

There are always among your patients many whose greatest need is simply more iron, calcium and vitamin D. To-day's food restrictions virtually preclude an extra supply of these nutritional factors by dietetic means. Caldeferrum tablets, presenting iron, calcium and vitamin D in stated amounts, give the physician a simple means of restoring and maintaining the necessary reserves by exact and regular dosage and (often an important consideration) at small expense. Indicated particularly in pregnancy, lactation, and adolescence, the ★ routine of 4 Caldeferrum Tablets a day supplies the additional intake required to guard against increased drain on the body's store. The chocolate coating of the tablets makes Caldeferrum acceptable to all patients.

★ The routine of 4 tablets supplies exsiccated ferrous sulphate 25 mg; calcium phosphate, 0.5 gm; vitamin D, 2,000 i.u.

Vitamin routine for every infant

Just as the infant is protected against vitamin C deficiency by a routine ration of orange juice, so he should be provided with extra vitamins A and D by means of some independent standardized preparation. This provision is a wise precaution for all infants, whether bottle-fed or breast-fed. In bottle-feeding the supplement is particularly advisable when liquid or whole dried milk is used. In breast-feeding it is a safeguard to the infant who may be suffering from a maternal dietary deficiency of these vitamins. A daily ten drops of Adexolin Liquid effectively satisfy the infant's dietary needs of vitamins A and D and build a valuable reserve. Powerful assistance is given to normal growth, to dental and skeletal development, and to resistance against infections. Being virtually tasteless, Adexolin Liquid can be given unnoticed in the bottle-feed, or in fruit juice—or even on the infant's tongue.

A 14cc. phial of Adexolin Liquid, costing 2/-, yields 450 drops—sufficient for nearly seven weeks. Even more economical are the 2 oz. bottle (6/-), the 4 oz. (10/-), and the 8 oz. (18/-). Prices (not applicable in Eire) are subject to usual professional discount

ADEXOLIN LIQUID

vitamins A and D for growth and well-being

Each cc. contains 12000 i.u. of vitamin A and 2000 i.u. of vitamin D—the equivalent of 20 cc. of medicinal cod-liver oil.

SURGICAL SERVICE
SALTAIR

Complete, Efficient & Comfortable

SUPPORT FOR THE LOWER ABDOMEN
IS AFFORDED BY
SALT'S ENTEROPTOSIS BELT

Support for the lower abdomen was the particular objective in view when a well-known Medical Man designed Salt's Enteroptosis Belt. This support is achieved without any constriction of the upper abdomen. Shaping at sides holds Belt well down, without under-straps, and though ample adjustment is provided, the minimum amount of fastening is necessary. It has cravat style back.

Fully described in Salt's Corset & Belt Book, which also contains handy Measure/Order forms for the doctor's use. A copy of this Book will be sent to any practitioner upon request.

London Consulting Rooms:
"OAKLEY HOUSE," 14-18, Bloomsbury St., W.C.1.
Female Fitters in attendance Monday to Friday.
Orthopædic Mechanician Wednesdays only.
By Appointment.

Guarantee
"We guarantee to alter exchange or accept the return of any appliance without cost ordered by the Medical Profession, if not found Suitable within fourteen days from date of supply."

Nuffield Provincial Hospitals Trust

SIR,—Your admirable leading article on the Nuffield Provincial Hospitals Trust (January 25, p. 125) was welcome to those of us who are engaged in solving the problems of hospital regionalization. There are, however, some statements therein which might give rise to misunderstanding and perhaps to apprehension.

Referring to the Medical Advisory Council as representative of "several specialisms in medical science," you hardly do justice to its composition. Although the council is not yet complete it does contain representatives of general practice, both urban and rural, general and specialized consulting practice, public health and preventive medicine, pathology, teaching and research. Moreover, its members are drawn from widely separated areas in England, Scotland, and Wales, and include several who have worked or are working with local authorities. Great distances have not deterred them from attendance at meetings in Oxford even in these days of slow and tiresome travel.

You suggest, too, that the main obstacle to our activities is "the reluctance of some local authorities to co-operate." My experience does not lead me to take that view. There *is* reluctance to be met with here and there on the part of local authorities *and* of voluntary hospitals, which is only to be expected before any new scheme or principle is accepted, but, generally speaking, local authorities have been most responsive and co-operative. Perhaps this may be due in part to the fact that the provisional Central Committee does already contain at least six members who are actively engaged in city and county council administration, a representation of local authorities which is likely to be increased in the near future.—I am, etc.,

Christ Church, Oxford, Feb. 3. E. FARQUHAR BUZZARD.

Insulin Supplies and Wartime Economy in Prescribing

SIR,—In recent months anxious letters from diabetics all over the country, but mostly from small towns and villages, have shown their difficulties in obtaining their accustomed supplies of insulin. Bombs have certainly destroyed some insulin supplies, but not enough to make any real difference to the abundant stocks in this country—of this diabetics and their doctors may rest assured—though local distribution has been temporarily upset. The manufacturers have noted that, besides the annual gradual increase in the sale of insulin, national emergencies like September, 1939, the fall of France, the beginning of the air "blitz," push up the insulin sales by 20% to 40% for a few weeks. As a result local supplies are almost depleted; diabetics cannot obtain all they want of their usual make or strength of insulin: they panic a little and press the local chemist, who makes unexpected demands on the manufacturer, and so on. So the local supply of insulin can be temporarily upset by greatly increased demands, especially when delayed distribution is sometimes inevitable. A recent article in the *Pharmaceutical Journal* (December 7, 1940) urged chemists to lay in larger stocks of insulin, and this, though all to the good of diabetics in some ways, had the unfortunate result of putting some manufacturers under difficulties and accentuated the local shortage in some areas. Doctors, chemists, and diabetics could help the manufacturers greatly in the adequate distribution of insulin by making no sudden increased calls for it, but quietly laying in adequate stocks by careful provision.

Also, by prescribing and using the more concentrated strengths of insulin all concerned could help greatly and contribute to national economy. One of the main difficulties for manufacturers now is the supply of suitable glass, and in this an obvious economy is possible. There are three strengths of insulin on the market—20, 40, and 80 units per c.cm. (this is unfortunately not generally realized)—and it is obvious that by prescribing the stronger solutions large numbers of bottles and packings could be saved. At present the weakest strength is still most widely used, and if 40 units per c.cm. insulin were prescribed instead of 20 units per c.cm., 20,000 bottles a week would be saved.

Apart from economy, there are other good reasons for using the stronger insulins. Most patients prefer them when they know about them, because they reduce the volume of the injection without making the accurate measurement, even with small doses, difficult. Again, at present numerous mistakes are made between the three strengths of insulin, which would ultimately be reduced by the use of only two varieties—40 and 80 units per c.cm. This would also bring soluble insulin into line with protamine insulin, of which no 20 units per c.cm. strength is manufactured. Personally I have not prescribed the weakest solution—20 units per c.cm.—for four years, think it unnecessary, and that its disappearance from the market would be a blessing to diabetics and manufacturers. Then we could have a standard insulin solution—U40 per c.cm.—for most general use and a stronger solution—U80 per c.cm. —for patients on very large doses. To effect such a change I suppose the *British Pharmacopoeia* and other necessarily slow-moving bodies must be concerned. In the meantime, therefore, I would urge the immediate prescription of the stronger insulins, with corresponding reduction of the amount drawn into the syringe.

Doctors should also reassure diabetics, who are often ridiculously conservative in their use of one particular make and strength of insulin, that all brands and strengths in this country are equally good and active, and can replace, if necessary, their favourite bottles, if the correct adjustment is made in the syringe when the strength—20, 40, or 80 units—is changed.

I would also make a plea for change in the clumsy nomenclature we use and the confusing differences in labelling used by our three manufacturers of insulin. In this letter I have had to waste your valuable space in talking about insulin 40 or 80 units per c.cm.—which means little to many patients and is a tongue-tying description. The Americans aptly call and label these insulins U40 and U80 (clear and short terms), and if this practice was adopted here in bold letters on the bottles much dangerous confusion between doctors, nurses, and patients about different strengths would be minimized.—I am, etc.,

London, W.1, Feb. 7. R. D. LAWRENCE.

Civilians Blinded in the War

SIR,—Attacks from the air have already resulted in a number of cases of blindness among civilians, and doctors responsible for the care of such cases are faced with a specially difficult task when the time comes for them to acquaint their patient with the fact that sight has been lost. However tactfully and wisely that information is imparted it is bound to be a shock, and I may be permitted, perhaps, to emphasize that the patient, when he learns the truth, should be at once assured that proper training will enable him to overcome the handicap he has now incurred, and that training and help of the most practical kind are available to him.

I take leave in this connexion to call the attention of doctors to the comprehensiveness of the system of blind welfare now established in this country. It provides for the education, social care, training, and employment of blind people of both sexes and of all ages. The county council or the county borough council of the area in which the patient's home is situated is responsible, under the Blind Persons Acts, for ensuring that every blind person is provided for according to his or her needs. Any hospital, therefore, which has a blind patient should notify the responsible local authority. If there is any doubt of the right person to address in the matter, we, at the National Institute for the Blind, will gladly act as intermediary and give any possible help.

May I add, Sir, that the rehabilitation and re-education of civilians who are blinded in the war is a matter of the keenest interest to us and other voluntary organizations which work in co-operation with the responsible local authorities in all parts of the country, and that no effort will be spared to meet their needs, however great they may be.—I am, etc.,

W. MCG. EAGAR,
London, W.1, Jan. 31. Secretary-General.

The Transfusion Problem

SIR,—We were interested in the last paragraph of Dr. DeGowin's letter on the transfusion problem (February 1, p. 169), concerning the temperature at which stored blood should be given.

We are in entire agreement with his statement that it is unnecessary to warm stored blood, beyond, perhaps, allowing it to come to room temperature by removing it from the refrigerator about thirty minutes before use. This is only done if time allows. As long as the drip method of transfusion is used we can see no possible danger at all, and, in fact, it is our personal experience since we ceased warming blood as a routine before transfusion that reactions have been far fewer. The probable explanation of this observation is that the rather haphazard method previously employed—namely, immersing the blood container in a receptacle with warm water at about 105° C., to which further hot water was added from time to time—caused overheating of the red blood cells in immediate contact with the glass container, resulting in the destruction of these cells.

In a short paper entitled "The Use of Placental Blood for Transfusion" published in January, 1939 (*Lancet*, **1**, 200), in collaboration with K. G. Seager, we stated: "We are now of the opinion that it is unnecessary to heat the blood before use."—We are, etc.,

Leicester, Feb. 4. E. M. WARD.

Optimum Calcium Requirement

SIR,—Dr. I. Harris and Messrs. J. T. Ireland and G. V. James, in summing up the conclusions of their article on optimum calcium requirement (January 11, p. 49), make very definite statements which, if correct, are of great interest to those concerned with dietetics and their social implications.

They state that there is no particular evidence to suggest that the great majority of our population suffer from the effects of calcium insufficiency; that the calcium intake of the present dietary regime is ample; that large sections of the population eat too much calcium-rich food; that there may be some indication for reducing food calcium but none for increasing it; and that half the population will suffer from the effects of hypercalcaemia if the calcium content of our diets is increased.

As these conclusions are so far-reaching it is worth while to examine critically the evidence on which they are based. To do this, however, one needs many more details than are given in this article. One would like to know, for instance, the method used to estimate the serum calcium; what type of diet was given to the patients in the experiments and how its calcium content was determined; whether the high calcium diets mentioned were arrived at by the addition of calcium salt, and if so what salt? Do the authors consider that the short period of fourteen days during which the experiments were conducted is sufficient to justify such sweeping conclusions as to calcium balance? Have they taken into account the fact that calcium intake must inevitably be greater than calcium absorption, which accounts for the increase in faecal calcium which they observed in their high-calcium-diet results? Regarding the patients' diets at home, it would be useful to know what tables of values were used in estimating the calcium content and the weekly wages of the patients in question.

The animal results as published are particularly inadequate. They do not tell us how many animals were kept on a calcium-rich diet, for how long, nor the nature of the diet or the method of estimating its calcium. Moreover, are we justified in drawing any conclusions as to human calcium needs from an animal with such very different dietetic habits as the rabbit?

We are told that calcium is second only to protein as an important factor in kidney strain, but we are given no inkling of the actual proportion of kidney work which comes under the heading of calcium secretion. The figures quoted give the misleading impression that the total kidney work in high and low calcium diets is 18.8/5.1 respectively, or 14.0/0.9 in the second case mentioned. Finally, one may ask if it is justifiable with such a common condition as arteriosclerosis to draw any conclusion from the Registrar-General's returns, since in many cases in which it occurs arteriosclerosis will not be mentioned on the death certificate.

Until more detailed and satisfactory results are available I see no reason to disagree with Sir John Orr's dictum that half our diets are deficient in calcium. As our knowledge of the subject grows it may be that we shall find more abundant clinical evidence of calcium deficiency. Studies of the type carried out by Miss Irene Allen (January 11, p. 44) may be a step in this direction. The mere fact that our existing views on diet are based on inadequate data is no excuse for attempting to disprove them with data which are equally, or even more, inadequate.—I am, etc.,

Northwood, Middlesex, Feb. 1. B. H. KIRMAN.

Differences in Infectivity at Home and Abroad

SIR,—I have recently returned from escorting 300 evacuee children to the United States. Shortly after we arrived there one of the children, a boy aged 5, developed a severe attack of chicken-pox, which I and the American doctors who saw him decided was most probably developed from an infection received in the United States. Reference to his medical documents which I had taken with me showed that he suffered from chicken-pox in England exactly a year before he went to the United States. Unfortunately the doctor who attended him then is now a prisoner of war, but I have obtained information from his locumtenent, who looked up the details of the attendances at that time, and discovered that the diagnosis was chicken-pox. The extraordinary thing about the attack in the United States was its extreme virulence, and it seems a justifiable conclusion to me that there is some difference between the infecting agent in the English variety of chicken-pox and the American variety. I wonder if this is an actual observed fact and if anybody can corroborate it. One would have thought that an attack of chicken-pox only a year previously would have guaranteed a fair degree of immunity to infection so shortly afterwards, and this is rather borne out by the fact that other children on the way over developed a mild form of chicken-pox, the infection from which was received in England. As it was more than three weeks after we landed in the States that the child developed this other attack it would seem that the infection was undoubtedly of the American variety.

All this prompts me to ask whether there may be similar differences in the infectivity of other diseases in the States as compared with the same diseases in England. I have observed in the Press that quantities of serum for immunization against diphtheria are being flown from the States for use in this country, and I should be interested to know whether it is possible that this serum may not immunize against our British brand of Klebs-Loeffler bacillus.—I am, etc.,

Wealdstone, Feb. 5. J. B. WRATHALL ROWE.

Prepared Bran in the Prevention of Constipation

SIR,—I hear that "All-Bran" has been classed with "luxury breakfast foods" and will cease to be obtainable when the present stock has been sold out. I have no financial interest in the manufacture of this preparation, but I am convinced that the impossibility of obtaining it would be harmful to the numerous persons who depend on it for the prevention of constipation. Many of them would feel themselves compelled again to resort to purgatives of various kinds, from which they have successfully freed themselves by the help of bran.

The truth is, of course, that All-Bran consists almost entirely of cellulose, which, as is well known, cannot be absorbed from the human alimentary canal and therefore cannot be termed a food in the ordinary sense. As it cannot be absorbed, it inevitably increases the bulk of the contents of the large bowel and thus favours defaecation. Everyone depends more or less on cellulose for the normal action of his bowels, but, just as some children require more vitamin D than others in order to escape rickets, so some individuals require a greater cellulose intake than others to avoid habitual constipation. I need not enter here into the reasons why some children require the intake of more vitamin D than others, or why some persons need more cellulose than others

in order to avoid constipation. Factors in early upbringing and general hygiene may have much to do with it, and especially the prevalent habitual use of purgatives of all kinds, though the constant use of purgatives has at last become less universal, thanks to popular teaching on the subject.

It is hardly an exaggeration to say that of the adult patients I formerly used to see in hospital as well as in private practice a large proportion thought that they could not possibly get on without the habitual use of purgatives. Many of the others avoided constipation by bulky diets, which, though they provided sufficient cellulose to avoid constipation, tended to induce obesity and other evil results of over-feeding—often aided in that respect by insufficient open-air exercise. In fact, the large meals which they took contained enough cellulose but too much nutritive material of various kinds, and thus, though their intake saved them from habitual constipation, the results of habitual over-nutrition tended to shorten their lives, making them die from degenerative diseases before their time—say, between 55 and 65 instead of between 65 and 75 or later.

For those persons whose bowels require a relatively large proportion of cellulose in order to act properly it is a hardship to cut off their bran supply. For many of them excess of the stringy cellulose of vegetables causes flatulence and does not act so well as does the granular cellulose material of All-Bran, which swells up to a mucilaginous consistence in the bowels. All-Bran is, as far as I know, the only properly prepared bran at present available in England, and it would be, I think, a great pity if the supply were cut off. How far ordinary bran, as given to animals, could be used for the same purpose, I am not able at present to say.—I am, etc.,

London, W.1, Feb. 5. F. PARKES WEBER.

Research in Stilboestrol

SIR,—In your issue of December 21, 1940, there is on page 876 a definite misstatement with regard to stilboestrol. This substance was produced as the result of a very long series of investigations in our respective departments, and if you refer to the various publications you will find acknowledgments to commercial firms for the assistance we received. Thus in the paper by Dodds and Lawson describing for the first time oestrogenic compounds which do not contain the phenanthrene nucleus (*Proc. roy. Soc.*, B, 1938, **125**, 222) we acknowledged the great help given by Dr. F. Lee Pyman, F.R.S., of Messrs. Boots Pure Drug Co., Ltd., who supplied us with a whole series of phenyl methanes and ethanes. Again, in the paper by Dodds, Golberg, Lawson, and Robinson (*Proc. roy. Soc.*, B, 1939, **127**, 140) acknowledgments are made to Messrs. Boots for assistance in the preparation of diethylstilboestrol and to the British Drug Houses, Ltd., for a communication respecting the properties of diethylstilboestrol.

Whilst it is true that the investigations were begun and carried out in university laboratories, it is definitely not true to say that the drug houses made no contribution whatever to the work.—We are, etc.,

E. C. DODDS.
R. ROBINSON.

The Courtauld Institute of Biochemistry, Middlesex Hospital Medical School, and the Dyson Perrins Laboratory, Oxford, Feb. 5.

*** While accepting the above correction, we would stress that the research on stilboestrol was initiated in university laboratories.—ED., *B.M.J.*

Recruits and Tuberculosis

SIR,—Examination of the chest for tuberculosis in recruits and other applicants for war work is more a dynamic or physiological than a static or anatomical problem. Our object is not so much to discover what lesions are present as to estimate their probable effect upon health under the new conditions of life—and this cannot in doubtful cases be done by physical examination alone, with or without x rays, or at one sitting. Moreover, we have to allow for undiscoverable lesions in the lungs and elsewhere.

During the last war as tuberculosis officer, and both earlier and later in sanatorium practice, I found many examples of quiescent or arrested tuberculosis in which without a practical test one could not estimate the chances of health. The story of Aesop and the traveller is apposite here. Some of my patients who had had tuberculous lesions in the lungs served in the Army with credit and without a breakdown; and, of course, thousands who have minimal tuberculous lesions in the body remain in excellent health.

In the Army, apart from injury, the chief differences from ordinary civil life depend upon over-exertion and lack of rest, irregular meals, exposure to trying weather or climate, sometimes on stuffy rooms or dusty or poisonous atmospheres. Local extension of a tuberculous lesion is usually very slow; but we may take any evidence of the leakage of toxins into the general circulation with imperfect compensation as a sign of activity. An exercise test with very careful thermometry will often help in doubtful cases. The usual methods of temperature-taking by nurses or overworked medical practitioners in civil life would, however, be of no use for such a test.—I am, etc.,

Farnham, Surrey, Feb. 1. F. R. WALTERS.

Prosthetic Ulcer of the Mouth

SIR,—I was much interested in Mr. H. T. Simmons's paper on prosthetic ulcer of the mouth (January 25, p. 119). I described this condition in 1939 (*Practitioner*, 1939, **143**, 113) under the designation of "denture ulcer and denture granuloma," the term "granuloma" being necessary, as many of these cases do not present themselves as ulcers. Hospital records do not present a large series, as many are treated in the out-patient department. It is, in my opinion, a relatively common condition, and this is not surprising in view of the neglect with which many persons treat their dentures. In a series of fifty-eight consecutive individuals, all of whom were wearing dentures and who were admitted to hospital for various surgical conditions, I found that fourteen had not had an adjustment or remodelling of their dentures carried out for ten years or more, the average period being twelve and a half years. It is significant that these individuals had not seen a dental surgeon for a similar period. Another interesting feature elicited was that in six instances the wearer was not in the habit of removing the denture for regular cleansing, and one woman had not removed her denture for several years. In this instance the woman states that she had on several occasions attempted to remove her denture, but had failed to do so. Other factors in the causation, in addition to those mentioned by Mr. Simmons, are alteration of the distribution of occlusive pressure and alteration in the action of the temporo-mandibular joint coincidental with the age changes at the angle of the jaw. Removal of the offending denture eliminates all pain, tenderness, and discomfort within a short space of time, but, once developed, the swelling does not appear to shrink, even when the causation factor is removed.

Provided the possibility of a denture granuloma is considered, it is not likely to be confused with a carcinoma of the gum, especially as the granuloma is covered by normal epithelium and is firm or elastic in consistence.

With regard to treatment, I think quicker healing can be obtained by an elliptical excision of the swelling, followed by loose suturing of the adjacent mucosa over the denuded area. This can be done under local anaesthesia, and healing is usually complete within ten days. My experience corresponds with that of Mr. Simmons in that these small lesions are extremely radio-resistant.

Finally, I suggest that the description "dental granuloma," implying cause and effect, is preferable to such terms as false epulis, localized hypertrophy or papilloma of the gum, or even prosthetic ulcer of the mouth, especially as the lesion may present as a granulomatous mass without ulceration.—I am, etc.,

Liverpool, Feb. 1. J. COSBIE ROSS.

SIR,—The condition described by Mr. H. T. Simmons in the *Journal* of January 25 is one well recognized by dentists. The ulceration and hypertrophy of the tissues in the lip or the cheek sulcus which is described is due to pressure of a denture.

Dentures are constructed, especially for edentulous mouths, to obtain the maximum amount of retention, and hence of stability. This entails making the "gum" portion of the

denture (that is, outer and inner rims) reasonably deep; it is a simple matter to reduce the depth, and therefore it is wiser to err in making it too deep rather than not deep enough. Consequently, it is usually necessary sooner or later to reduce the depth, or, to use the dentist's term, "ease" a denture. Patients vary greatly in their sensitiveness to the pressure of dentures: some describe the slightest abrasion of mucous membrane as acute discomfort, while others will tolerate, with little or no inconvenience, a denture which is cutting deeply into the gums. If for some reason or other the necessary easing of a denture is not carried out, the condition described by Mr. Simmons may in time result, and is more likely to do so in those patients with less sensitive gums who are, consequently, less likely to seek relief.

The condition is simply an ulceration due to pressure (that is, trauma), such as would occur in other parts of the body under similar conditions. It does, as Mr. Simmons states, appear to occur more often in the front than the back of the mouth and in the lower rather than in the upper jaw. The groove or grooves in which the denture lodges or dislodges is/are formed by an overgrowth of the gums (that is, mucous membrane) rather than by a destruction of the gums; the condition is similar to that of a tightly fitting ring which may become embedded in the tissues if the finger should swell. The gums eventually become "ploughed" into deep furrows and ridges by constant movement of the denture, especially if its edges are sharp. In a pronounced case this may take months or years to develop. The situation is determined by the site of pressure; the fraenum of the upper and lower lip may account for its more frequent appearance in the middle line. Atrophy of the alveolus, by allowing the denture to sink more deeply into the gums, and also by favouring its mobility, is probably an important factor in initiating this condition.

I have observed this condition in varying degrees on very many occasions—probably a hundred or even more—and have rarely seen, as far as I can recollect, malignancy as a result, although naturally the condition does not confer immunity. Ulceration, even in the deeper portions of the furrows, is not necessarily present, but, if present, the lymphatic glands in the neighbourhood may be enlarged, as with any other form of surface infection. Age, sex, and site play no very important part provided the above conditions are present, but it is undoubtedly more common, as Mr. Simmons remarks, in edentulous mouths, which are usually associated with advance in years.

The treatment I have adopted in those cases requiring operation is: (1) To infiltrate with a local anaesthetic the linear ridges or fringes of mucous membrane. (2) To grasp the free margin of the fringe with one or more pairs of pressure forceps according to its extent. (3) To excise the fringe (nearly at a level with its base or origin) with scissors curved on the flat, the fringe being held taut meanwhile by means of the pressure forceps. (4) To deal with any secondary fringes in a similar way. (5) To bring the edges of the wound together with one or more stitches, if this is necessary. (6) To instruct patients to discard their dentures until the wound has soundly healed (usually two or three months) and then to have either their present denture modified or preferably a new one made to the altered conditions of the mouth. Reducing the edge of the denture alone is insufficient except in slight cases, when the commencing elevations or ridges consist of vascular granulation tissue and not the firm fibrous tissue which is formed later. I described this method of treatment in 1911 (Annual Reports, Royal Dental Hospital, published by John Bale Sons and Danielsson, London).—I am, etc.,

London, W.1, Feb. 3. F. COLEMAN.

Acute Bronchiolitis in Children

SIR,—The morbid anatomy of bronchitis and bronchiolitis and its relation to their clinical manifestations has been the subject of our investigations for a long time. Therefore we would like to make some additional remarks to the excellent article by Drs. D. Hubble and G. R. Osborn (January 25, p. 107). We agree with the authors of the article that bronchiolitis in influenza is a very grave complication indeed. From the point of view of morbid histology influenza-bronchiolitis holds a kind of key position. We have described this ty with its peculiar features in a recent paper (*Archives of Dise in Childhood*, December, 1940). We pointed out in this pap that bronchiolitis is a complicated affair, and that a numb of types must be differentiated. Two main groups may distinguished: catarrhal and mural bronchiolitis. The lat again consists of three types which are the result of more less intense inflammation: simple, proliferative, and destructi mural bronchiolitis. The proliferative type is most frequent met with in influenza, measles, etc. This peculiar form described in detail in the article mentioned.

Secretion, which plays such an important part in the catar and inflammation of the bronchi and bronchioli, is discuss in an article to be published shortly. The distribution of t glands and of other secreting tissue all over the air-conducti tubes is described in this paper, which is based on extensi investigations with a special method. In addition the artic gives an exact histological definition of bronchi and bronchio This, we believe, will help to separate the clinical picture bronchiolitis from other conditions affecting the bronchial tre —We are, etc.,

STEFAN ENGEL.
London, N.W.7, Jan. 31. G. H. NEWNS.

Sterilization of Instruments

SIR,—Dr. H. J. Parish (January 25, p. 130) stresses on again the importance of sterilizing instruments by heat f diphtheria and other inoculations. Many doctors think th frequent boiling of needles soon blunts them, and it is n altogether easy to make suitable arrangements for the rapi inoculation of large numbers of children, etc. In view of th enormous number of inoculations required at the preser time, details of a simple routine which I think meets the nee of sterilizing by heat quite adequately may be of gener interest.

One syringe is used for performing the inoculation, an should, for rapid working, be large enough to contain ten t fifteen doses at one filling; a second syringe—preferably 5 c.cm.—is in the hands of an assistant, who can be instructe in her duties in a few moments. The second syringe is fir filled with sterile water, and when the first inoculation ha been performed the needle is taken off by the operator an placed on the syringe held upright by the assistant. She the squirts a few minims of water to clear the needle and dips th needle only for 10 seconds into a pan of boiling water. Th syringe is then held with the needle upright and a sma amount of air drawn through the needle. Emptying th needle in this way minimizes the very real danger that som water remaining in the needle may be injected with the inocu lation and materially upset the accuracy of small doses such a 0.1 c.cm. of A.P.T. By this time the operator has inoculate a second child, and he takes off his needle and puts it on th nozzle of the assistant's syringe, from which she has remove the freshly sterilized needle and proceeds to put it on th vacant nozzle of the operator's syringe. In this way onl two needles are used, and I find in practice that this arrange ment works very well and rapidly. The basis for this metho is to be found in the interim report on "Hospital Infectio of War Wounds" in the *Journal* of December 28, 1940 (p 895), where it is stated: "A dip lasting five seconds was lethal in all tests." If this applies to artery forceps, which hav quite a definite heat capacity, it must apply even more strongl in the case of a hypodermic needle, which has practically n heat capacity at all. Needless to say, it is only the cannul of the needle which needs to be dipped into the water eac time, and if desired sterilized forceps could be used instead o fingers to remove the needles from one syringe to the other though I doubt if this is necessary with moderate care.

If there is any real danger from trusting to alcohol steriliza tion it seems right that the authorities should forbid reliance on this method for mass inoculations of all kinds, and th method I have outlined enables one to utilize heat sterilizatio with a minimum of difficulty, and also a minimum of equip ment and assistance. I personally have not been able t detect any blunting of the needle after many such short-im mersions in boiling water, and I think it is only prolonge boiling which is likely to have any such effect.—I am, etc.,

Winsford, Feb. 1. W. N. LEAK.

Adrenaline in Asthma

SIR,—The correspondence resulting from the letter of Sir Arthur Hurst (September 7, 1940, p. 337) has raised many points of interest. Apart from the reported failure of adrenaline in some cases, the danger of morphine in severe asthma has received timely warning from Dr. M. Park (January 11, p. 65).

In addition Dr. Park raises other points of interest in the very difficult cases of status asthmaticus.

(1) Can the pathological conditions which cause the different types of status asthmaticus be diagnosed clinically from the history or examination? These often can, for the causes of status asthmaticus are often the causes which produce the ordinary attack of asthma in the same individual. Occasionally it is otherwise, as in the case of a male asthmatic, hyperpietic, who was under treatment for asthma in Stobhill Hospital. While improvement was being maintained he acquired an attack of fibrositis. For its relief he was given veganin tablets by a house-physician, and within thirty minutes he commenced having severe asthma. This defied adrenaline for three days, and he looked like dying. Intravenous aminophylline was then suggested, and its success was immediate. It would be interesting to know whether this medicine has good effect on other aspirin-sensitives.

(2) If so, are any of the different methods of treatment applicable particularly to a particular pathological state? and (3) Are there any other indications for the selection of the method of treatment, any contraindications, or is there anything noteworthy in the method of administration? Adrenaline should always be tried first and repeated, but three points in the treatment should always be kept in mind. First, the difficulty in getting rid of tough mucus plugs. As mentioned previously (November 16, p. 684), 30 to 40 grains of sodium iodide in 250 c.cm. glucose-saline solution should be given intravenously if there is no iodide intolerance. Other methods include bronchoscopic suction and emesis. Secondly, dehydration; this must be combated by saline-glucose intravenously, and it may be a life-saving measure. Also, the glucose supplies a source of energy. Thirdly, rest, oxygen inhalations, ether rectally or by inhalation, or barbiturates variously administered may be tried in appropriate doses in suitable cases. The discussion of the treatment of status asthmaticus is one on which considerable time and space may be spent, but its ultimate conquest depends essentially on the alteration of the physical or biochemical constitution of the individual which predisposes to the asthmatic diathesis.—I am, etc.,

Glasgow, Jan. 19. GEORGE KRASNER.

The Fixed First-aid Post

SIR,—For some time past we have been reading in the *Journal* many views on the use and service of mobile units in A.R.P. These can only be gauged by the results and useful work done in each district. Of the fixed first-aid post we have heard nothing, except that some of your correspondents choose to ignore them, and speak of all cases being sent to hospital, just as if no intermediate source of help existed between the mobile unit and the hospital ward. As one in charge of a fixed F.A.P. in a London district which has suffered heavily, I think that excessive numbers of casualties are being whisked off to hospitals without any attempt being made reasonably to segregate them. This is due to the difficulties met with by the hard-worked ambulance services, etc.

In my view, most cases of injury, major or minor, can be dealt with satisfactorily at any fixed F.A.P. and so prevent the terrible rush of cases to already overworked and lessening numbers of hospitals. I know the answer to this suggestion is that the Ministry says "only walking cases to the F.A.P." It is with this attitude that I join issue. Most cases at the post can receive appropriate anti-shock treatment; haemorrhage can be controlled; fractures can be temporarily splinted; and patients allowed to recover in the warmth and bright surroundings of the F.A.P. After a reasonable time the ambulances can be summoned, and if correct treatment has been given the casualties can then be removed to hospital, where they can be put to bed and perhaps left till the following morning. This is much better than having ambulances bumping about through streets unknown to the drivers in the dark and sometimes taking up to half an hour to reach the allotted hospital. This would also give the hospital staff a breathing space wherein to deal with other casualties as they arrive.

It is, in my view, an inhuman act to turn away from the F.A.P. any case capable of receiving adequate temporary treatment there, however serious the injury may be. I do not know what the experience and views of other medical officers of a F.A.P. are, but I fancy none of them would shirk dealing with any form of casualty brought to them.—I am, etc.,

DANIEL HUGHES,

Feb. 5 M.O., Fixed F.A.P., London.

The Mobile Unit in Action

SIR,—It has been interesting to read the recent correspondence appearing in your *Journal* on the subject of mobile units, especially as everyone is not agreed as to the utility of these. The fully equipped and manned mobile unit consists of: (*a*) the personnel (a doctor, with one or more qualified nurses and lay persons trained in first aid); (*b*) the equipment; (*c*) the unit itself. As regards (*a*) it will generally be acceded that such a mobile personnel taken to the incident by car can be of great assistance in dealing with the injured: (*b*) this is at present carried in the unit, but such equipment could be taken to the incident by a light vehicle; (*c*) a mobile surgical unit large enough to accommodate patients during treatment might be of help at the incident, but many of the units now in commission are really not suitable for giving treatment in the unit itself, so that in such cases the only value of the unit is as a conveyance of equipment.

It would be interesting to have the views of medical men who have had actual experience with mobile units in action, especially as to whether the utility of the unit consists mainly in its transport value. Are many mobile units worthy of the label "mobile first-aid posts"?—I am, etc.,

J. F. MACDONALD.

Chelmsford, Feb. 8. Medical Officer of Health.

Certificates for Night-shift Workers

SIR,—It has come to my knowledge during my duties in connexion with industry that it is viewed with considerable concern that certain men and women wish to avoid their due share of night-shift working.

At the present moment the Government is insisting, not only on such night work, but upon a record being kept of the hours each machine is in use; and those who, for no real physical disability, acquire from their doctors certificates recommending that they be excused night work, not only throw vital production out of gear, but in certain instances provoke others to plead the same medical excuse, with increasing interference with output and unrest in the shop concerned.

I would therefore put in an earnest plea for my colleagues in the profession to give such certificates only after satisfying themselves to the hilt that night work is definitely injuring the health of the individual worker.—I am, etc.,

Jan. 31. AN EXAMINING FACTORY SURGEON.

Medicine in a Changing World

SIR,—With reference to your leading article "Medicine in a Changing World" (January 18, p. 91), the first part of Sir John Orr's statement, "The medical profession contains within it experts on every subject that affects human welfare," members of any other profession or organization could lay claim to a similar statement, but public opinion, I think, would be against it in either case.

The second part of Sir John's statement, "It is the only organized group of men competent to make a statement on human needs," would, if true, place the onus of all economic and political affairs on the medical profession. On the economic side it is not pleasant to read in Sir John's statement that "the profession has been too much occupied with its own remuneration and failed to recognize its responsibilities towards the bigger issues of national life."

I think your leading article sums up the case clearly, and the majority would agree that "the cobbler must stick to his

last"; it does not suggest that any influence should be brought to bear on any individual or group of members of the profession regarding their political opinions, as some of the correspondence against the leading article implies. Probably those best qualified to speak on economics will be found in the ranks of general practitioners and the country doctors; they have the day work and most of the night work to do, which possibly explains why they are generally silent on these matters; however, I feel it would be the general opinion that it is no concern of medicine to take part in economic or political affairs.—I am, etc.,

Exmouth, Feb. 3. FREDK. COCK.

SIR,—Several contributors have justly criticized your editorial regarding the obligations of the medical profession to state Man's minimum needs and to exert its influence under our democratic political system to get these satisfied. I wish particularly to support the plea of Dr. F. Dillon (January 25, p. 132) that politics be no longer regarded as only a plaything of political parties. Even the most extreme form of *laissez-faire* demands some sort of communal administration. Recent trends, however, show that in future, from necessity, more and more control of the activities of the community must be exercised by national and international Governments and legislatures. Are these to frame their policies according to reason and by scientific methods with full knowledge of the facts? Surely in our own province it is the duty of our profession, collectively and individually, to see that they do. An enormous amount of research is being carried on to rid mankind of the ravages of disease. But what facilities for research are provided for studying ways of curing these social and economic ills which are of far greater importance as destroyers of human well-being than disease? Such research ought to be carried out on a scientific basis independently of political parties with their fixed dogmas.

As an alternative to Hitler's New Order there has got to be offered a new system of democracy, purged of the inadequacies of the old and guaranteeing the minimum necessities of life to all. Only thus can democracy regain support in Europe. I should like to point out that there is already a movement, federal union, run on a non-party basis, advocating a European democratic system to replace that of Fascism. The federal Government that it contemplates would have powers and obligations to ensure that all citizens were guaranteed the minimum necessities of life, including medical attention, by making the satisfaction of these needs the first call on the resources of the community.—I am, etc.,

London, Feb. 5. D. G. FF. EDWARD.

Medical Planning Commission

SIR,—Since the announcement of the Commission in the *Supplement* of January 4 much correspondence upon the matter has appeared in the *Journal*. This correspondence reveals serious doubts about both the adequacy and representative character of this important body. These doubts have had particular reference to the preponderance of elderly members. These doubts may or may not be removed, but if we may judge from past experience of centralized committees it is safe to predict that the main part of the Commission's work will be done by a small group who are able to meet regularly. It is also safe to suppose that this group will be composed mainly of London members and of the older provincial members. Time and distance under war conditions will prevent the younger and more professionally active members from taking more than a perfunctory part in the proceedings.

We are told that the visions and aspirations of the younger men and women will not be overlooked. This sounds much more like a condescending gesture than an invitation to co-operation. Indeed, it suggests rather that it is the intention of the promoters that the Commission shall be dominated by the "less younger" of our colleagues.

The fear that the profession will be faced by a *fait accompli* has already been expressed. But even this is perhaps not the greatest danger. Surely the most serious result of an unrepresentative report is the deep division within the profession which it is likely to produce. The spectacle of a divided profession is not one likely to dispose Parliament to give that consideration to medical opinion which is desirable. Better no report than a disputed report. Is this now inevitable? One can but hope that it is not. Is it too late to urge the reorganization of the Commission on a regional basis? It is widely believed that a regional medical service has the best prospect of success, and in any event regional problems and conditions must be given full and knowledgeable consideration. Adequate representation, backed by the regular attendance of members, would be ensured, and an agreed report could be expected.

The suggestion is that seven or eight regional committees, preferably elected, would be set up, together with several special committees to deal with specific problems. These committees would work simultaneously according to an agreed programme, and report at regular intervals to a central body which would be composed of representatives of the committees together with an equal number of members nominated by such bodies as the Royal Colleges, the Medical Schools, and the B.M.A. The chairman could profitably be a wise and judicial layman. The function of this central body would be the progressive integration of the committee reports into a balanced whole. The widest publicity in the medical press throughout the proceedings is an essential feature.

It is considered that the less frequent meetings of this much smaller body need present no obstacle to regular attendance, especially if the provincial members were compensated for their time and their expenses defrayed, as indeed is only fair.

It is true that the B.M.A. has promised that Divisions and Branches "will have a chance to study and if necessary to criticize" the findings of the Commission. But if this is to be considered as a method of discovering and focusing the considered view of the profession on the vast problems under discussion, it is surely a *reductio ad absurdum in excelsis*. What Division or Branch, faced with a document of 300 or 400 pages, could adequately digest, let alone criticize, it within a reasonable time? And if they could, what effect are their several and possibly diverse critiques likely to produce? We all know the answer. Furthermore, not all the members of the profession are members of the B.M.A. or other bodies represented on the Commission as at present constituted.

We have a chance to mould a future National Medical Service. Let us not lose it.—I am, etc.,

Newcastle-upon-Tyne, Feb. 1. A. G. OGILVIE.

SIR,—It is with some disappointment that many of us have read the list of those whom the B.M.A. have selected to plan for the future of our profession. We did not expect that so many of what may be termed without disrespect "the old crowd" would be again called together to form the key personnel of this planning commission, whose decisions will be of such vital importance to most of us.

It is specifically mentioned that "much thought has been given to the age distribution of members of the commission." I have ventured, therefore to determine this, so far as is possible from reference books. This research yields the following results: of the fifty-seven members whose names are given, seven appear to be over 70. There are six between 65 and 70; nine between 60 and 65; eighteen between 50 and 60; eighteen between 45 and 50; and eleven under 45.

Sincerely as I value the experience which a ripe maturity can contribute to most problems, I would venture to maintain that it is the "under forty-fives" who should be chiefly represented where the issue is the future environment in which they are to live their lives and practise their art after this war. We shall no doubt be told that "youth" will be further represented on the subcommittees; nevertheless I would suggest that it would be better to reverse the principle, and see to it that "age and experience" were adequately represented on the subcommittees, and that the main body of the Commission should represent an average age not higher than (say) 50 years.

A further point causes me some surprise. The medical personnel of the Forces must by now represent the largest form of State medical service in this country. I see no representation of this important new body of opinion, many of whom are perhaps more concerned as to what the future holds in store for them than are their colleagues who still remain in civil life. It seems certain that many of these men who now have experience of both civil and State-controlled medicine might have much to contribute to the deliberations

of such a commission in view of the rapid and enlightened development which is still taking place in this sphere. Many of them are contributing actively to this development. It would appear that the B.M.A. are themselves not yet fully aware of the extent of this, and I may perhaps be permitted to quote some recent words of Prof. F. A. E. Crew, F.R.S. (in the opening contribution to a discussion arranged by the Edinburgh Branch of the B.M.A.). He said: "When I look around the [Army] Medical Services as they are even now taking shape, I marvel at their comprehensiveness and their promise of completeness, at the simple beauty of their design and the efficiency of their functioning. And I am led to wonder whether we as a society can ever be content to let this organization disintegrate when the war ends."—I am, etc.,

Jan. 19. W. S. C. COPEMAN, M.D., F.R.C.P.

Tobacco and Symptoms of Duodenal Ulceration

SIR,—With regard to dyspepsia in the Army, which you have been discussing recently in your columns, I can from personal experience confirm the fact that one can have symptoms almost, if not quite, identical with those of duodenal ulcer and yet no ulceration be present.

There are a number of factors which contribute to the development of these symptoms in a soldier—nervous excitement, overwork and worry, diet, etc.—but there is one serious exciting and aggravating cause—namely, cigarette smoking. Before the French collapse a kind friend sent a million cigarettes to the troops in France, and I feel sure that most physicians would agree that a million glucose sweets or malted milk tablets would have been a much better gift, and could be made just as popular among friends. I think it a decided disservice to our men to encourage this cigarette smoking, which would not be tolerated in the case of athletes or when perfect training was desired, which it should be in the case of soldiers. We must not allow the apparent unkindness of depriving our gallant men of the comfort of their cigarette to blind us to the bigger and more important question of their highest physical fitness and welfare.

One final point: it is sometimes forgotten that belladonna is most valuable in relieving the spasm which is an underlying factor in these cases.—I am, etc.,

Ilford, Feb. 5. N. BEATTIE.

Universities and Colleges

UNIVERSITY OF OXFORD

In Congregation on February 4 an offer from Viscount Nuffield to give to the University £25,000 to encourage research in ophthalmology was gratefully accepted. Arising out of this, a decree was adopted authorizing the appointment of a research assistant to the Margaret Ogilvie Reader in Ophthalmology for a maximum of five years and at a salary not exceeding £600 a year, and providing money from the residue of the gift for accommodation, equipment, and staff. The duties of the person holding the new post will be to assist the Reader in researches, whether of a clinical nature or otherwise, into the causes and cure of diseases affecting vision, and if he is a medical practitioner he will be debarred from private practice while in office.

In Congregation on February 18, at 2 p.m., a statute will be brought forward declaring that a candidate for the degree of Bachelor of Medicine shall not be allowed to sit more than three times for the examination in human anatomy and human physiology in the First Examination for that degree without leave of the Board of the Faculty of Medicine. If the statute is approved a decree will be proposed that it shall not apply to any person matriculated before Hilary Term, 1941.

Dr. William Brown has been reappointed Wilde Reader in Mental Philosophy for five years from June 9, 1941.

The Theodore Williams Scholarship in Pathology, 1940, has been divided between M. P. Lewis, B.A., and R. G. Ladkin, B.A.

UNIVERSITY OF CAMBRIDGE

In Congregation on February 7 it was resolved that the First M.B. Examination shall begin on March 17 in the present term, and on October 2 in the Michaelmas term of this year.

The following medical degrees were conferred:

M.D.—*O. N. Roussel.

M.B., B.Chir.—*W. E. D. Maile, *H. D. S. Vellacott, G. E. H. Emerson, D. N. White.

* By proxy.

During January the titles of the degrees of M.B., B.Chir. were conferred by diploma on P. G. Holman of Newnham College.

Congregations during the present term will be held on Saturday, March 1, and Friday, March 14, at 2 p.m.

The Services

D.D.M.S., SCOTTISH COMMAND

Brigadier J. A. Manifold, D.S.O., late R.A.M.C., has been selected for promotion to major-general on March 1, when he will take up the appointment of Deputy Director of Medical Services, Scottish Command. He will be succeeded as Director of Hygiene, the War Office, by Brigadier D. T. Richardson, M.C., late R.A.M.C.

D.D.M.S., EASTERN COMMAND

Brigadier O. W. McSheehy, D.S.O., O.B.E., late R.A.M.C., has been selected for promotion to major-general on March 26, when he will take up the appointment of Deputy Director of Medical Services, Eastern Command. He will be succeeded as Deputy Director-General, Army Medical Services, the War Office, by Brigadier A. Hood, C.B.E., late R.A.M.C.

EFFICIENCY DECORATION

The King has conferred the Efficiency Decoration of the Territorial Army on Colonel John Elvin Rusby, M.C.; Lieut.-Colonels Joseph Alexander Bingham, David Justin Davies, and Maxwell Hamilton Summers; and Temporary Lieut.-Colonel David Saunders Jones.

MENTIONS IN DISPATCHES

Corrigenda

In the list of officers whose names have been brought to notice in recognition of distinguished services in connexion with operations in the field, March to June, 1940, published in the *Journal* of January 4, the name of Lieut. H. L. Connor, R.A.M.C., was omitted, and the initials of Major Y. Moore and Lieut. A. E. Burgess, R.A.M.C., should read Major J. Y. Moore and Lieut. W. M. Burgess, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Probationary Temporary Surgeon Lieut. CHARLES LEON PRETRE, R.N.V.R. (H.M.S. *Acheron*), is posted as "Missing, Presumed Killed" in an Admiralty Casualty List published on February 4. He qualified M.R.C.S., L.R.C.P. in 1939 and his home was at Dagenham.

Surgeon Lieut. GEOFFREY RAYMOND EDWARD MAXTED, R.N.V.R., died on active service in December, 1940, aged 26. He was the younger son of Dr. and Mrs. E. B. Maxted of Clifton, Bristol, and was educated at Bristol University, where he graduated M.B., Ch.B. in 1938.

Surgeon Lieut. ROBERT DUDLEY ROPER, R.N.V.R., has died suddenly, aged 34. He was the son of the late Dr. H. J. Roper, who died in 1938, and was educated at Cambridge University, where he graduated B.Chir. in 1933, and at St. Bartholomew's Hospital. He also took the M.R.C.S., L.R.C.P. in 1933 and the Cambridge M.B. two years later. He had held the posts of house-surgeon to the ear, nose, and throat department and resident anaesthetist at Charing Cross Hospital and casualty house-surgeon and clinical assistant to the skin department at St. Bartholomew's Hospital. Before the war he was honorary anaesthetist to Charing Cross Hospital, the Hospital of St. John and St. Elizabeth, and the Connaught Hospital.

ROYAL AIR FORCE

The death is announced, in January on active service, of Flying Officer ARTHUR RICHARD YATES of Sisland, near Loddon, Norfolk. He qualified M.R.C.S., L.R.C.P. in 1935. He leaves a widow and two children.

ROYAL ARMY MEDICAL CORPS

The name of Lieut. FRANCIS CUTHBERTSON MCLAREN is included as "Died" in an Army Casualty List published on January 31. He was the son of Mr. and Mrs. T. McLaren of Broughty Ferry and was educated at Glasgow University,

where he graduated M.B., Ch.B. in 1938. After filling the posts of house-surgeon at Victoria Infirmary, Glasgow, and junior assistant medical officer at the North Middlesex Hospital, London, he recently joined the R.A.M.C. He leaves a widow.

DEATHS IN THE SERVICES

Colonel ROBERT WILLIAM CLEMENTS, C.M.G., D.S.O., late *R.A.M.C., died at Ootacamund, Southern India, on January 22*, aged 70. He was born at Pomeroy, Co. Tyrone, on April 7, 1870, was educated at Queen's College, Galway, took the M.B., B.Ch., B.A.O. of the Royal University of Ireland in 1895, and the Cambridge D.P.H. and the Liverpool D.T.M. in 1906. Entering the Army as surgeon lieutenant in 1896, he became lieutenant-colonel in 1915, colonel in 1917, and retired in 1922. He served throughout the war of 1914–18 and was mentioned in dispatches five times, receiving the D.S.O. in 1917 and the C.M.G. in 1918. After retirement he settled in India.

Fleet Surgeon WILLIAM GORDON STOTT, R.N. (ret.), died at Aberdeen on February 5. He was educated at Aberdeen University, where he graduated M.B., C.M. in 1885, after which he entered the Royal Navy, becoming fleet surgeon in 1903.

Obituary

SIR WILLIAM HORROCKS

Sir LEONARD HILL sends the following appreciation of the late Sir William Horrocks:

As a member of the Army Medical Advisory Board I was associated with the late Colonel Horrocks under Sir Alfred Keogh, who was Director-General, A.M.S., when the Germans made their first gas attack in the last war and very nearly broke through the line. Means had to be taken at once to provide defence against gas. A German submarine had been lately captured in which muslin face masks were found, and at the instigation, as I was told, of the First Lord of the Admiralty (then Mr. Winston Churchill) the women of England were thereupon asked to make such masks. These obviously were no good: meanwhile Horrocks designed the flannel hood respirator, which covered the whole head and was fitted with eye-pieces and impregnated with suitable chemicals for absorbing gas. Breathing took place through the pores of the flannel. This respirator was used successfully until the box respirator could be designed and manufactured. So that no time might be wasted over official financial delay, Horrocks told me he had gone out and ordered the flannel on his own responsibility. He carried out very valuable work in initiating the Chemical Warfare Committee and in furthering generally the hygiene of the Army. His son was taken prisoner, and he told me a code had been prepared in case of need by which his son was able to communicate safely with him. Horrocks also told me that his work in Malta had made clear that Mediterranean fever was transmitted by goats' milk, and so brought about the means of prevention. Bruce communicated this discovery in England, and Horrocks felt strongly that credit had not been justly accorded to him. Up to his death he had continued to edit the *Journal* of the R.A.M.C. His services to the Army and to medical science were very great.

JAMES ALLAN, M.D., D.P.H.

Dr. James Allan, who died at his home in Roundhay, aged 88, was for half of his long life medical superintendent of St. James's Hospital, Leeds, and one of the best-known medical officers in the North of England. At the time of his appointment the Leeds Workhouse Infirmary, as it was then called, was insufficient in many respects. A complete transformation took place and room was gradually made for 1,200 patients, including 200 mental cases, while notable changes were made in the class and number of nurses and in the provision made for them. When he retired in 1925 an unusual honour was paid him by the unveiling of a tablet recording his manifold services as medical superintendent, and the late Lord Moynihan spoke in warm terms of his work, saying that tens of thousands of patients had passed through Dr. Allan's hands.

James Allan graduated M.A. at the University of Aberdeen in 1874, M.B., C.M., with honours, in 1877, and M.D. in 1880; twenty years later he took the Cambridge D.P.H. Before his appointment in 1881 to the post at Leeds he had been assistant medical officer at the Wandsworth Infirmary and house-surgeon and house-physician at the Northern Hospital, Liverpool. He was for many years an active and zealous member of the British Medical Association, joining it in 1882. He represented the Leeds Division at sixteen Annual Meetings, was honorary secretary of the Division for twenty-five years (1906–31), and chairman in 1932–3. His colleagues of the Yorkshire Branch of the Association elected him president in 1921; he was also a past-president of the Leeds and West Riding Medico-Chirurgical Society.

ANDREW SPROTT, M.B., C.M.

We regret to record the death on January 29 of Dr. Andrew Sprott from coronary thrombosis. He had been in failing health during the last twelve months, but his death came with painful suddenness to his many friends in Appleby and the surrounding district, where he was held in the highest esteem and universal affection.

Andrew Sprott came of an old Galloway family. He was born 74 years ago in Wigtownshire, where his father was a well-known farmer who died young, but not before his eldest son developed a knowledge and love of beasts, birds, and flowers surpassed by few, and, furthermore, a capacity for painstaking hard work, a patient zeal and understanding of his fellow men which made him beloved by all with whom he came in contact. He graduated M.B., C.M. at Glasgow University in 1887, and started his professional career in a large country practice as assistant to the late Dr. J. W. Fawcitt of Broughton-in-Furness, and between these two there sprang up a friendship and affection which lasted throughout life. He married his friend's sister, Annie, with whom he had an ideally happy life. He then proceeded to Glenridding, on the shores of Ullswater, where he carried on the wild country practice often under hazardous conditions, but where, also, he found occasional time for his favourite sport of fly-fishing. With the advent of a young family, he transferred his activities to Appleby, the county town of Westmorland. There he built up a large and successful practice (from which he retired three years ago) and a reputation as a good doctor of outstanding kindness and integrity. He was a man of great ability and courage, who spared no effort on behalf of his patients: he was painstaking in the establishment of the diagnoses of his cases, and followed up accurate diagnosis with up-to-date treatment. He had a vivid interest in modern methods and was never behind the times in spite of his fifty years of practice. During the war of 1914–18 he was responsible for the establishment of a Red Cross hospital in Appleby, of which he was the medical officer, eventually becoming county director of the British Red Cross Association. He also took a great interest in the St. John Ambulance Brigade. He was a member of the British Medical Association for thirty-three years.

On his retirement the people of Appleby and district made him a presentation on such a generous scale that he was positively embarrassed, and in his modest way he said to the writer, "I never expected or deserved this." He was a great gardener and a great botanist. His keen interest in botany was a source of joy which he shared with his wife, his daughter, and his invalid son, who died some eighteen months ago after fourteen years in bed as an indirect result of his service during the last war. His eldest son died on active service in Mesopotamia in 1917. He is survived by his widow, a daughter, and son who lives in the Far East.

Dr. ALEXANDER GUNN AULD, who died at the end of January in his eighty-first year, is likely to be remembered for his work on asthma, hay fever, migraine, and related diseases. From quite early days, alike in the laboratory and at the bedside, he made these topics his peculiar province, and

it was along a strict line of scientific inquiry that he reached the practice of what he named pyrogenic therapy—that is, the introduction of peptones and allied bodies into the blood stream. In his hands the practice had a large measure of success, and its value has been widely recognized by other workers. The record of Auld's researches and teaching is to be found in his book entitled *Asthma, Hay Fever, Migraine and Allied Diseases*. It is with this contribution to practical therapeutics that his name is particularly associated. Personally his habit of mind was almost severely scientific and he cultivated philosophy and literary ambitions; for some years he was the editor of the *Medical Magazine*. His professional qualifications included M.D.Glasg., M.R.C.P.Lond., D.P.H. Oxon. He had been a member of the council of the London and Counties Medical Protection Society, and was for some years a lecturer on clinical medicine and pathology at the North London Postgraduate College.

The death occurred in January from enemy action of KERIDWEN ST. VALENTINE ARMSTRONG, M.D., D.P.H., while on duty for the Emergency Medical Service. She was the wife of Dr. J. V. Armstrong. Keridwen Edwards came to University College Hospital from Cardiff University in 1919, and so was among the first group of women students admitted to that hospital. She gained the Liston gold medal in surgery and qualified in 1921 shortly after her twenty-first birthday. After resident appointments at King Edward VII Hospital, Windsor, the Evelina Hospital for Children, Glan Ely Tuberculosis Hospital, Cardiff, and the ear, nose, and throat department of University College Hospital, she entered the L.C.C. Fever Hospital Service and was appointed to the Grove Hospital, Tooting. She spent a year at Queen Mary's Hospital for Children, Carshalton, before her marriage in 1934. That is her medical record, and certainly it indicates the length and breadth of her service as a doctor. Her friends, however, will find interest and comfort in the fact that the war which has now taken her life gave her opportunity to practise that particular branch of medicine which had always appealed to her as her especial vocation at the outset of her career. The hospital of which her husband is the medical superintendent was incorporated into the Emergency Medical Service, and her part within that organization was with the orthopaedic unit. She was thus able to use and develop her talents in a sphere where she was most conscious of her skill. Mrs. Armstrong had, however, a place among her friends which even surpassed her place in her profession. She first appeared as a pretty and eager young woman, younger than her contemporaries and challenging in her outlook. To immature medical students the challenge was at first disconcerting, but her charm and her mental integrity, as well as her competence, yielded to her all the sweet awards of work and friendship. And those qualities which showed themselves when she came from Wales and joined her fellow students at U.C.H. persisted throughout her life. Her death has broken a partnership which cemented two careers. The happiness of her married life, which delighted their many friends, served their work and gave benefit to all who knew them or were in their care.

The death occurred in January from enemy action of WINIFRED PORTER, M.B., Ch.B.Vict. Born in Leigh in 1909, she began her medical studies at Manchester in 1928. After qualifying in 1934 she had been house-physician to the South London Hospital and Victoria Hospital, Chelsea, and later resident medical officer to the Princess Louise Hospital. She was also resident medical officer to the Convalescent Home, Swanley. Dr. Porter was showing great promise as a psychiatrist, having studied her specialty at the Maudsley Hospital and later at the Retreat, in Yorkshire, from where she went to Cane Hill Hospital, Coulsdon. She had a very high reputation among the staff, being possessed of keen clinical acumen and marked practical ability. A colleague writes: The death of Dr. Winifred Porter has deprived the medical profession of a very promising young psychiatrist. She was a woman of exceptional intelligence and charm, beloved by colleagues and patients alike. In her work she was efficient and always to be relied on in an emergency. As an anaesthetist she was outstanding, and had a high reputation among the hospital staff and consultants. She had a sharp clinical acumen and a marked proficiency at getting straight to the core of any matter in hand. She always had the good of her patients at heart, and took a particular interest in the welfare of the nursing staff in her wards. Dr. Porter was a great lover of the truth and fearless in the expression of her opinions when she felt them justified. She was a true champion of the cause of liberty and would unhesitatingly have sacrificed her life if she had thought the cause would benefit. As it is her death is one more example of the cruel barbarism of indiscriminate bombing, which can gain our enemies nothing and only serve to steel us to endure to the end. Dr. Porter was engaged to Surgeon Lieut. K. O'Connor, R.N., and to him and her parents all those of us who knew her sterling worth tend our heartfelt sympathies.

We regret to announce the death in his eighty-eighth year of Sir JOHN MCFADYEAN, LL.D., formerly Principal of the Royal Veterinary College, who was vice-president of the Section of Pathology when the British Medical Association held its Annual Meeting in Edinburgh in 1898. His death removes one of the pioneers who built up veterinary science and changed the status of veterinary medicine. A native of Wigtownshire, he was born on June 17, 1853, and after training at the Edinburgh Veterinary College took the M.R.C.V.S. in 1876. Thereupon he entered as a medical student, graduating M.B., C.M.Ed. in 1882 and B.Sc. in the following year, and became lecturer on anatomy and pathology at the Edinburgh Veterinary College. His next post was that of dean of the Royal Veterinary College in Camden Town, London; when the chair of comparative pathology was established there he was appointed to it, and he served as Principal from 1894 to 1927. McFadyean edited the *Journal of Comparative Pathology and Therapeutics* for many years. With his medical and veterinary qualifications and his belief in the future of comparative medicine it was most appropriate that he should be invited to hold office at the Edinburgh Annual Meeting of the B.M.A. He was knighted in 1905 and the University of Aberdeen conferred its honorary LL.D. upon him.

Medical Notes in Parliament

Mr. James Griffiths has given notice that when the House goes into Committee on the Civil Estimates he will call attention to deficiencies of the National Health Insurance Act and move a resolution.

War Damage Bill

During the consideration of the War Damage Bill on February 5, Clause 29 (Property held for Charitable Purposes) was amended, on the motion of Mr. CHARLES WILLIAMS, to cover specifically any properties engaged in "the making of provision for the cure or mitigation or prevention of, or for the care of persons suffering from or subject to, any disease or infirmity or disability affecting human beings (including the care of women before, during, and after childbirth)." He said the amendment was to make clear that provisions for these women came under the Bill.

On Clause 42 (Insurance Schemes) Sir FRANCIS FREMANTLE moved on February 5 that "business" in this part of the Bill should include "any trade, profession, employment, or vocation." He said he was concerned to include in "profession" medical men. It was thought by the medical profession that it would be best to use the interpretation of the word "business" which was used in the Income Tax Act. The memorandum in the Bill said the word "business" did include professions, but there was nothing in the Bill to say so. Mr LYTTLETON said the word "business" covered the professions, and to introduce the words proposed by Sir Francis would legally be dangerous. Sir Francis withdrew the proposed amendment.

Medical Man-power

Mr. MANDER asserted on February 14 that widespread dissatisfaction at present existed in the medical profession with regard to the failure to utilize to the fullest extent the services of the medical profession in the national effort, owing

to lack of co-ordination and co-operation between the Emergency Medical Service, the medical services of the armed Forces, and the general body of civilian medical practitioners. He asked Mr. MacDonald to consider appointing a small non-medical committee to investigate the most effective organization for utilizing to the best advantage the medical services of the country. Mr. MACDONALD replied that the Service Ministers, the Secretary for Scotland, and he were not aware of any widespread dissatisfaction, but recently had the advice of a committee appointed to consider the steps necessary to secure a proper allocation of the available medical manpower between civilian and military services. The committee consisted of Sir Arthur Robinson, as chairman, and three medical men with wide experience of the various branches of the profession—namely, Sir John Fraser, Sir Kaye Le Fleming, and Prof. R. M. F. Picken. Their report was now receiving the active consideration of these Ministers.

Mr. MANDER offered to supply evidence of dissatisfaction.

Mr. WOODBURN asked Mr. MacDonald to induce the medical profession to relinquish some of its trade-union etiquette so that its work should be better spread over the population.

Butter Ration of Tuberculous Persons.—On February 11 Mr. PARKER asked the Parliamentary Secretary to the Ministry of Food whether a larger ration of butter could be provided for patients suffering from tuberculosis, as the present two ounces was insufficient for nourishment purposes. Major LLOYD GEORGE said that the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council was considering the position of invalids, including tuberculous patients, in the light of the present food restrictions.

Medical News

The Hospital for Sick Children, Great Ormond Street, would like members of the medical profession to know that through the kind co-operation of the Watford Peace Memorial Hospital it has been found possible, as a wartime measure, to open consultative out-patient clinics there. At first clinics will be held once a week, beginning on Friday, March 7. Medical and surgical cases should attend at 10 a.m. and ear, nose, and throat cases at noon. These clinics will be extended later if necessary. The clinics will be conducted by members of the visiting medical staff of the Hospital for Sick Children, and new cases must be recommended by a doctor. Appointments should be made by letter through: The Almoner to the Hospital for Sick Children Clinic, Watford Peace Memorial Hospital, Watford, Herts.

The University of Manchester has arranged a week-end course on factory medical services for medical practitioners. It will be held on Saturday and Sunday, March 1 and 2, and the fee is one guinea. Full details of the course may be had from the Director of Extramural Studies, The University, Manchester, 13.

Surgeon-General Thomas Parran, of the United States Public Health Service, will be entertained at luncheon by the Society of Medical Officers of Health on Friday, February 21, at the Piccadilly Hotel, W., at 12.45 for 1 p.m. Tickets (7s. 6d., including wine and gratuities) are obtainable by members of the Society from the acting Executive Secretary at Tavistock House South, Tavistock Square, W.C.1, not later than February 19. Members may be accompanied by one representative of their local authority.

A meeting of the Shaftesbury Military Hospital Medical Society will be held at the hospital on Tuesday, February 18, when Colonel L. E. H. Whitby will give an address on "Transfusion for War Conditions."

The Medical Women's Federation is arranging a course of six lectures on social anthropology to be given at the London School of Hygiene and Tropical Medicine from March 3 to 8 at 4.30 p.m. It is intended mainly for doctors and nurses working over-seas, but members of the public will be welcome. Fee for the course is 1½ guineas, with a reduction for missionaries. Tickets and further information may be obtained from Dr. Margaret Balfour, 14, Sylvan Road, Upper Norwood, S.E.19, or at the first lecture.

A meeting of the Faculty of Radiologists will be held at 32, Welbeck Street, W., on Friday, February 21. At 10.30 a.m. the Therapy Section has arranged a discussion on "The Organization of Radiotherapy in Wartime," to be opened by Mr. Malcolm Donaldson, followed by Mr. E. Rock Carling, Mr. G. F. Stebbing, and Dr. Ralston Paterson; at 2 p.m. the Skinner Lecture on "Cancer of the Bladder" will be delivered by Dr Ralston Paterson; and at 3 p.m. before the Diagnostic Section there will be a demonstration on "The Anatomy and Radiology of the Bronchial Glands," by Dr. Stefan Engel. A discussion will follow. Copies of the report of the discussion on the organization of radiotherapy in wartime will be available to members in due course at a cost of 2s. each. Members requiring copies should apply to the secretary.

Applications are invited for Leverhulme fellowships or grants in aid of research, intended for senior workers who are prevented from carrying out research work by routine duties or pressure of other work. The trustees are also prepared to consider applications from groups of workers engaged upon co-operative programmes of research, particularly from those engaged upon long-distance programmes or in institutions in which the normal facilities for research have been curtailed by the war. Forms of application, returnable by March 1, may be had from Dr. L. Haden Guest, M.P., Kinscote House, 1, Watergate, Blackfriars, London, E.C.4.

Diabetics, who already have triple rations of butter and margarine, are now to have a triple meat ration; information to this effect has been sent to local food committees. The Ministry of Health has recently emphasized the need for those who regularly take insulin, and who therefore would run special risks should they become air-raid casualties, to carry on their persons some indication that they are diabetics. They can obtain from the Diabetic Association, 124, Baker Street, London, W.1, on receipt of a stamped addressed envelope, a suitable card for carrying inside their identity card on which can be written the usual dose of insulin, the treatment for an overdose, and their medical adviser's name and address.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

During the week under review there were increases in the incidence of cerebrospinal fever, enteric fever, and pneumonia (primary and influenzal) in England and Wales and in Scotland, where increases in notifications of measles and whooping-cough were also recorded, but these may be due rather to an extension of the system of notification or "intimation" than to an actual high increase.

Influenza for Week Ending February 1

The return of influenza deaths for the week ending February 1 for the 126 great towns, 176, again almost precisely repeats the figures of 1929; in that year we had 99, 122, 179, and, in this year, 99, 120, 176. At first sight this is ominous, for in 1929 influenza became very severe. But in that year 99 was reached a fortnight earlier, and time is an important element. In general, the later a recrudescence begins the less likely is it to reach severe proportions. The most recent returns for London show a reduction in the numbers of daily admissions to hospital of cases of influenza, bronchitis, and pneumonia cases. It now appears probable that there will not be a sudden great rise in influenza deaths, but mortality is likely to continue to increase. The age distribution of the deaths is of the normal type. 56% are at ages over 65 and 5% at ages under 25. In the corresponding week for 1939 deaths from influenza numbered 210, and, for 1940, 353.

Cerebrospinal Fever

The incidence of cerebrospinal fever has been increasing and it is more prevalent than last year (266 notifications as against 107); a steep rise was then noted in the last week of January and the peak reached in the week ended March 2, the decline of the epidemic was much more leisurely and more irregular than its rise. With prompt diagnosis and adequate treatment the case fatality rarely exceeds 5%. The number of administrative health areas affected rose from forty-one to forty-four, in eighteen of which more than 5 cases were recorded—namely, Lancaster 46, York, West Riding, 22, Warwick 19, Gloucester 14, London 14, Glamorgan 12, Wiltshire 9, Southampton 8, Surrey 8, Durham, Essex, and Kent 7 each, Derby, Middlesex, Northampton, Nottingham, Yorks, North Riding, and Monmouth 6 each. The notifications for the week ending February 1 (just received) were 326.

Measles and Whooping-cough.—The fall in the incidence of measles and whooping-cough, which remain by far the most prevalent acute infectious diseases in this country, and the generally low case fatality of both diseases are gratifying in view of the abnormal conditions under which many of those at risk are living.

During 1940, as the accompanying graph shows, measles steadily gained ground: a marked decline occurred in the four weeks August 3 to August 31, which is probably due to extrinsic factors rather than to changes in the virulence or dispersal potential of the causative organism. This fluctuation in the epidemic curve found no counterpart in the deaths in the principal towns. Despite the increase of the

Graph showing cases of and deaths from measles and whooping-cough in the thirteen four-weekly periods in 1940 (cases for England and Wales and deaths in the 126 principal towns).

disease and the prevalence of catarrhal infections, measles proved less fatal towards the end of the year; there has been a tendency towards a higher case fatality in recent weeks, but exact observations are impossible as returns for deaths are available only for the principal towns. The uniform low curve of whooping-cough is in sharp contrast to that of measles. Concurrent respiratory infections are of less moment in measles than in whooping-cough, which is a mild disease in summer and deadly in winter. Measles is potentially dangerous to the young at any season, but in recent years has been remarkably mild, for which a complete explanation is not yet forthcoming. Improved nutritional standards, increased facilities for home nursing and hospital treatment, probably all play their part.

No. 2

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended January 11, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash—denotes no cases; a blank space denotes disease not notifiable or no return available.

§ Includes figures for puerperal fever.

with it is a matter of some difficulty, and we have awaited the report of the Shakespeare Commission before coming to a final conclusion.

It has now been decided that it is not necessary and would not be right to establish a new medical service on the lines suggested by your Association, as was done in the case of the unaccompanied children, and that the proper course is to ensure that the existing medical service provided by the public assistance authorities is readily available for the class in question. In November last we urged public assistance authorities to review their services, and we have recently circularized them again on the same matter, informing them, among other things, that we would entertain proposals for the "open choice" system of Poor Law Medical Service if they regarded that as suitable. You will recollect that your Association suggested this system in your letter of October 2, 1939.

I may add that the new advice to public assistance authorities goes in one respect further than the suggestions made by your Association, since it has now been indicated that they will be reimbursed for their expenditure in providing medical services for persons privately as well as persons officially evacuated.—Yours sincerely,

E. J. MAUDE.

The Ministry of Health circular (dated February 4) to which reference is made in the Ministry's letter is Circular 2283, which is given in full below:

EVACUATION: HEALTH AND WELFARE SERVICES

1. I am directed by the Minister of Health to state that he has had under review the arrangements for the provision of health and welfare services for evacuated and homeless persons who come into a local authority's area.

2. In the circular of November 16, 1940 (Circular 2204, with which the present circular should be read), the Minister indicated that, in addition to the special services (such as sick bays) provided in connexion with evacuation, all the local authorities' normal health and welfare services should be fully extended to all evacuated and homeless persons coming into their areas—whether billeted or privately accommodated—in the same way as to the ordinary inhabitants, and that the newcomers to the area should be acquainted with the services available.

Reimbursement of Expenditure to Local Authorities

3 While proper economy should be exercised in the provision of the services, the Minister is anxious that action on the part of receiving authorities should not be hampered by any misunderstanding as to the incidence of the cost. It has already been recognized that expenditure incurred in extending services for evacuated or homeless persons who are billeted or accommodated at the expense of the Government would be reimbursed under Section 56 of the Civil Defence Act, 1939.

4. The Minister has now decided that the same principle should be applied to the provision of services for persons who have temporarily left their homes in the evacuation areas and have made private arrangements for their accommodation in reception or neutral areas. He is therefore prepared to reimburse to local authorities in reception or neutral areas any net additional expenditure (less recoveries made from the persons concerned according to the authority's normal practice) incurred on or after September 1, 1940, in extending their health or welfare services (including any necessary extension of the District Medical Service of the Public Assistance Authority) to any persons who have removed from an evacuation area under private arrangements but whose residence in the new area may be assumed to be of a temporary kind. It is recognized that no hard-and-fast rule can be laid down for distinguishing between temporary and permanent removals, but in general a rough guide will be found in the answer to the question whether the person who has removed remains liable to pay any rent or rates in respect of his house in an evacuation area, or would be liable but for damage to the house owing to enemy action.

Domiciliary Medical Treatment

5. Domiciliary medical treatment for unaccompanied school children accommodated under the Government Evacuation Scheme will continue to be provided under the arrangements set out in paragraph 16 of Circular 1882. For insured persons medical attention is available under the National Health Insurance Acts, and, for those able to pay the necessary fees, by private practitioners in the normal way. For other persons provision will be made through the District Medical Service

6. In Circular 2204 Public Assistance Authorities were requested to have special regard to the provisions of an adequate District Medical Service to meet the needs of an increased population. It is important that the service should be readily accessible, and that the arrangements enabling the services of a doctor to be obtained should be as simple and expeditious as possible; this will be of particular importance in extensive rural districts in which the calls upon the service by the ordinary residents are few but which may have received considerable numbers of people who have been accustomed to rely on the District Medical Officers for any necessary domiciliary treatment.

7. In some areas it may be found convenient to provide the necessary service for evacuated persons by means of a panel of contracting general practitioners (generally known as the "open choice" system), while having due regard to the rights of existing District Medical Officers, and the Minister will be prepared, on application being made in each case, to consider the dispensations from the Public Assistance Order, 1930, needed to enable this course to be adopted.

8. The Minister requests that the authority will review the position and satisfy themselves that their arrangements are adequate to meet the needs of the situation. Wherever it is proposed to extend the service by additional appointments of temporary or assistant District Medical Officers, application should be made without delay to the Senior Regional Officer for prior approval.

Infectious Disease

9. Arrangements for dealing with infectious disease are of particular importance in view of the large numbers of children who have left evacuation areas during the last few months, and the fact that the months immediately to come are those in which the incidence of infectious disease is usually at its highest.

10. The authority will appreciate the importance of arranging for hospital treatment for the more serious cases which require such treatment. In so far as facilities in a particular district may not be adequate in the event of a local epidemic, they should make such arrangements as are practicable with neighbouring authorities.

11. While time and other factors will not permit of the building of new accommodation for immediate needs, existing hospital accommodation can be supplemented by the temporary use of existing buildings suitable for the purpose. If additional accommodation has to be improvised, either for cases of infectious disease normally treated in hospital or for cases of minor infectious disease which might not in ordinary circumstances call for removal to hospital but cannot be adequately nursed in billets, proposals for its provision should be submitted to the Senior Regional Officer.

12. The cost incurred in making the provision in paragraphs 11 and 12, and also in the provision of sick bays for the nursing of minor ailments on the lines indicated in Circular 2204, will, of course, fall within the general principles of reimbursement in respect of all local services laid down in paragraphs 3 and 4 above. The normal practice of the authority as hospital authority with regard to the recovery of cost or part cost of treatment in hospital should be applied to patients admitted for treatment or those responsible for them.

Other Hospital Treatment

13. The Minister has also reviewed the position with regard to the provision of hospital treatment for the various classes of evacuated persons. General hospital treatment is already provided, as a direct financial responsibility of the Minister, at hospitals within the Emergency Hospital Scheme for all unaccompanied evacuated children. It has now been decided that from the date of this circular the facilities available to unaccompanied children under the Emergency Hospital Scheme should be extended, so far as available accommodation at any time permits, to all other homeless and evacuated persons billeted or otherwise accommodated at the Government's expense, and also to those persons privately removing from evacuation into reception or neutral areas, who are defined in paragraph 4 above. Contributions to this cost of treatment will, of course, be recovered by the hospital from the persons concerned, in the case of all the additional classes covered by this extension, on the usual basis adopted by the hospital concerned. A more detailed communication is being sent on this subject to all local authorities with hospitals included in the Emergency Hospital Scheme and to voluntary hospitals so included.

14. Expenditure on institutional treatment provided by local authorities under a specialist service—for example, maternity, tuberculosis—or in general hospitals or institutions not in the Emergency Hospital Scheme will rank for reimbursement on the principles in paragraphs 3 and 4 above as additional costs incurred in extending local services.

General

15. In administrative counties the county council are responsible for some of the services mentioned in this circular, and the county district authorities are responsible for others. It is impor-

int that there should be effective co-ordination of these services, nd that the services available over the county as a whole should e used to the best possible effect. The county council have from ie outset assisted to this end in connexion with the Evacuation cheme, and it is considered that the county medical officer of ealth should, in consultation with the medical officers of health or the county district, be in a position to secure the most effective se of the medical and health services.

16. Evacuation areas for the purposes of this circular are the reas set out in Appendix A to Circular 2170 of October 8, 1940, ircular 2243 of December 18, 1940, and Circular 2277 of January 5, 1941, and any other areas subsequently declared to be evacuaon areas for the purposes of the Evacuation Scheme as from the ate of their declaration.

17. Expenditure in respect of which reimbursement is sought nder the extended arrangements (other than those for the admission f patients by the Emergency Hospital Scheme in paragraph 13) will equire the approval of the Senior Regional Officer of the Ministry or the Region concerned in the way prescribed for expenditure inking as an evacuation charge in Circular 1954 of January 22, 940.

18. Claims by authorities for the reimbursement of any additional xpenditure under this circular (other than those in respect of the dmission of patients by the Emergency Hospital Scheme under aragraph 13) should be submitted with the claims made in respect f expenditure incurred under Section 56 of the Civil Defence ct, 1939.

A copy of this circular is enclosed for the information of the inancial officer of the council, and a copy has been forwarded to he medical officer of health.

Correspondence

Occasion for Groans

SIR,—Recent letters in the *Journal*, in my opinion, rightly riticize the undemocratic "appointment" of a Commission to orrelate medical services. Again the general practitioner will e denied a full voice in matters which concern him and his atients most intimately. Another letter has raised the quesion of the inadequate capitation fee. I would draw attention o an increased burden of work which has not been stressed—amely, the ante-natal care of female insured persons. In my xperience these patients are being increasingly referred to heir "own doctor" for transient rises in blood pressure, *having been once under suspicion for toxaemia of pregnancy* hey are naturally a care and responsibility during the rest of heir pregnancy. My impression is that panel practitioners can through the correspondence page of the *Journal* during in odd moment of leisure and relaxation, heartily endorse nost of the complaints made by members, groan wearily at he unfairness of their lot, and retire to oft-interrupted lumber. There would be less occasion for groans if they trongly voiced their opinion to the executive officers of the Association and compelled them to take more interest in their pressing problems.—I am, etc.,

Jan. 31. JOHN J. FITZPATRICK.

Recruitment of Medical Students

SIR,—As the problem of man-power is again the subject of consideration by Parliament the following points submitted to a city Medical War Committee, who forwarded it to the University Faculty, may be of interest.

1. Now that the medical profession is selectively conscripted it is neither right nor just to exclude the medical students registered before the war from this method of recruiting.

2. Since the matriculation examination has been abolished for entrants to degree courses at Northern universities and one or two years' subsidiary study has been substituted the degree student taking this longer curriculum is at a disadvantage in competing with his colleagues for licence examinations with their lower standards of entry. In consequence few degree students are able to complete the five terms necessary for exemption before attaining the age of 20.

3. The inequity of the five-term system is emphasized by the irregularity of the calling-up dates and the wide variation in the dates of university terms. (The student who fails repeatedly after completing five terms has an advantage over his brilliant colleague.)

4. A recent B.M.A. circular stated that non-military medical posts require 3,700 doctors annually, and only 2,400 qualify annually. If the present method of recruiting students continues the supply of doctors will be decreased further.

5. The earlier that anatomy and physiology courses are completed the sooner the students could be employed at clinical work in war hospitals. At present the bombing of large teaching centres has reduced the facilities for study, already more difficult by the mental strain of war circumstances.

6. The leaders of the profession have a definite obligation to the community and are responsible for safeguarding the future of the profession by ensuring that the best type of entrant of high standard is not lost to the profession. Other professions and skilled industries have urged similar claims for their pupils and apprentices. It is suggested that each Local Medical War Committee should bring the matter before a Medical Faculty and the Central Medical War Committee as a very urgent problem for reference to the appropriate Ministry.

If selective conscription of medical students registered before the war is not adopted I suggest that medical students who have commenced their fifth term should be exempted and should be required to undertake an appropriate type of national service.

Since submission of the above the new calling-up envisages exemption of all dental and medical students.—I am, etc.,

Leeds, Feb. 2. Z. P. FERNANDEZ.

INSULIN: ECONOMY IN PRESCRIBING AND VIALS

Those who regularly take insulin are asked by the Ministry of Health to help national economy by using double-strength (40 units per c.cm.) or the quadruple-strength (80 units per c.cm.) instead of the single-strength insulin (20 units per c.cm.), thereby effecting a considerable economy in glass bottles. They should consult their usual medical adviser and get his approval to an easy adjustment of the dosage so as to obtain the same therapeutic effect. It has been calculated that if all users of single-strength insulin used the double strength there would be a total saving of approximately 20,000 bottles a week. The Ministry states that there are ample stocks of insulin in the country; local shortages of particular brands are due to difficulties of distribution and in the supply of vials. Doctors are therefore asked not to specify a particular brand in their prescriptions. We publish in the *Journal* this week (p. 251) a letter from Dr. R. D. Lawrence on this subject.

British Medical Association

Branch and Division Meetings to be Held

METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.—At Derry and Toms, High Street, Kensington, Thursday, February 20, 2.30 p.m. Count Jan Balinski Lindahl (Director of the Polish Research Centre): Poland under the German and Soviet Occupation.

Meetings of Branches and Divisions

BATH, BRISTOL, AND SOMERSET BRANCH: WEST SOMERSET DIVISION

At a meeting of the West Somerset Division, held at Taunton on November 21, with Mr. J. R. NICHOLSON-LAILEY in the chair, Brigadier P. H. MITCHINER gave a British Medical Association Lecture on "The Immediate Treatment of Air-raid Casualties." He said that the proportion of dead to wounded was one to two. Of the wounded one-third were so seriously hurt as to be entirely beyond surgical aid; a large proportion of the remainder were so slightly injured as to require little surgery, although many had serious nervous disturbances. Head wounds were rare; abdominal wounds were not common, but when they occurred there was likely to be partial or complete evisceration. The commonest injuries were multiple small superficial wounds, generally on the posterior surface. Discussing first aid he emphasized that first-aid parties should not attempt dressings or splinting, but, after dealing with haemorrhage and covering the patients warmly, should convey the patients as quickly as possible to a first-aid

post. When patients reached hospital shock was very severe, and they should be treated before being taken to the theatre unless there was haemorrhage. If the pulse rate dropped transfusion was not necessary, but if the pulse rate did not fall then transfusion should be carried out, whole blood being preferable to serum or plasma. The blood should be given slowly, one pint and never more than two pints. Morphine should be given freely, 1/2 to 1 grain, as small doses were useless; children did better with tinct. opii. Scopolamine should be used with caution. If patients were cyanosed they should be given oxygen, but not merely because respirations were slow. For all large wounds there should be complete excision and exploration under gas-and-oxygen anaesthesia. Sutures should never be inserted if there was the slightest tension. Fractures should be excised, packed with vaseline gauze, and closed with plaster but kept under observation for three days. He was not in favour of local applications of sulphanilamide; they had no local effect and were wasted, as they merely acted by absorption. It was better to give 2 grammes of sulphanilamide by the mouth in hot lemonade or citric acid every four hours. Sulphanilamide should be used for burns at once. In the first-aid treatment no attempt should be made to clean the burn; tannic jelly or tea compresses should be applied, and the patient treated for shock. In hospital, patients suffering from burns should be given intravenous concentrated serum, or plasma, but not whole blood or saline. When the pulse rate fell gas and oxygen should be given, not ether, chloroform, or intravenous barbiturate. All dead skin, blebs, etc., should be removed and the skin disinfected for six inches round wound. Tannic acid or gentian violet should be applied. With burns on the face the eyes should be covered and the face dusted with powdered sulphanilamide or 1% gentian violet; the same treatment should be applied to perineal burns.

WAR EMERGENCY FORMULARY COMMITTEE

The members of the War Emergency Formulary Committee and the bodies they represent are as follows: Dr. H. Davis, voluntary hospitals; Dr. E. A. Gregg, British Medical Association; Prof. J. A. Gunn, Pharmacopoeia Commission; Dr. P. Hamill, Royal College of Physicians; Dr. C. H. Hampshire, Therapeutic Requirements Committee of the Medical Research Council; Mr. R. Dawson Hutchinson, Ministry of Health; Dr. Lewis Lilley, British Medical Association; Mr. H. N. Linstead, Pharmaceutical Society; Mr. A. R. Melhuish, National Pharmaceutical Union; Mr. A. Mortimer, Wholesale Drug Trade Association; Mr. F. B. Royal, London County Council; Dr. J. W. G. Steell, Ministry of Health. The secretary of the committee is Mr. H. L. F. Walton, who may be addressed c/o The Ministry of Health (Room 559), Caxton House West, Tothill Street, Westminster, London, S.W.1. One meeting has already been held.

Medical Services of H.M. Forces Appointments

ROYAL NAVY

Surgeon Lieut. J. L. S. Steele-Perkins to be Surgeon Lieutenant-Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Temporary Surgeon Lieut. H. C. A Johnston to be Temporary Surgeon Lieutenant

ROYAL AIR FORCE

Flying Officer on probation B. Fellows has been confirmed in his appointment.

ROYAL AIR FORCE VOLUNTEER RESERVE

To be Squadron Leaders for the duration of hostilities: R. Sampson, R. N Ironside, W. M. Morris, M P. Ellis, J. H. Hunt, K. A. Latter.

Flying Officers W M. Philip, R. R. Foote, G. J. Marks, A. A. Butler, G. Hutchison, C G Rob, J. S. Davies, W. M. R. Henderson, N. P. Shields, P A. Gimson, E B Nicol, and D. A. P. Stephen have been promoted to the war substantive rank of Flight Lieutenant.

To be Flying Officers for the duration of hostilities: T. N. Arthur, R. F. Braithwaite, G. A. Ewen, K. Froome, J. D. Gray, E. W. Miles, J. B. O'Meara, J. R. Sides, C. G. Woolgrove, J. M. Marchant, B. E. Betty, A. Morgenstein, K. M. Willis, J. Walker, A H. Nelson, T. M. Mansbridge, J. Grieve, J. B. Coltman, H. F. D. Whitelaw, H. Clifton, W. B. Thorburn.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Major D. W. John, M.C., has ceased to belong to the Reserve of Officers on account of ill-health.

Captain B Malaher to be Brevet Major, under the provisions of Article 168, Royal Warrant for Pay and Promotion, 1940.

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Lieut. (War Substantive Captain) I. S Clal has ceased to belong to the Supplementary Reserve of Officers on account of ill-health.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

War Substantive Major T. L Hastings, M.C., has relinquished his commission on account of ill-health and retained his rank

Captain J. I. Watkins has relinquished his commission on account of ill-health.

Lieut. J. W. L. Follows, from Royal Signals, Territorial Army, to be Lieutenant.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Substantive Captains A. W. L. Smith and H. Ward have relinquished their commissions on account of ill-health.

Lieut. T. J. Mullins to take rank and precedence in his Corps and in the Army as if his appointment as Lieut. bore the date November 18, 1940.

Lieut. F. M. J. McKerran has relinquished his commission on account of ill-health.

INDIAN MEDICAL SERVICE

Major-Generals W. H. Hamilton, C.B., C.I.E., C.B.E., D.S.O., and G. G. Jolly, C.I.E., have been granted the local rank of Lieutenant-General.

COLONIAL MEDICAL SERVICE

A. H. B. Pearce, L.R.C.P. & S.Ed., D.P.H., has been reappointed Deputy Director of Medical Services, British Guiana.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Mon.* to *Fri.*, Special course of lectures on War Surgery. *Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m., Post-mortem Demonstration. *Tues.*, 11 a.m., Paediatric Clinic, Dr. R. Lightwood. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical). 3 p.m., Clinico-pathological Conference (Surgical). *Thurs.*, 2 p.m., Radiological Conference, Dr. Duncan White. *Fri.*, 2 p.m., Clinico-pathological Conference (Gynaecological).

EDINBURGH POSTGRADUATE LECTURES.—At Edinburgh Royal Infirmary. *Thurs.*, 4.30 p.m. Prof. J. A. Gunn: The Action of Drugs on the Human Uterus.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At Royal Society of Medicine, 1, Wimpole Street, W., *Mon.*, 3 p.m. Dr. A. J. E. Cave: The Comparative Anatomy and Evolution of the Paranasal Sinuses.

ROYAL SOCIETY OF MEDICINE

Section of Comparative Medicine.—Tues., 2.15 p.m. Discussion: Fluorosis in Man and Animals. Openers, Prof. T. J. Bosworth, Mr. F. Blakemore, Dr. H. H. Green, and Dr. M. Murray. Paper by Dr. Eugene Nassau: Culture of Tubercle Bacilli from Laryngeal Swabs

Section of Dermatology.—Thurs., 2.30 p.m. Presidential Address by Major W. J. O'Donovan: A Skin Convoy.

Section of Orthopaedics.—Sat., 11.30 a.m. Meeting at Chertsey. Discussion: Injuries to Peripheral Nerves. Opener, Mr. W. Rowley Bristow. Followed by Dr. J. St. C. Elkington.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Knowbury (Shropshire) is vacant. Applications to the Chief Inspector of Factories, Cleland House, Page Street, S.W.1, by February 18.

MEDICAL REFEREES UNDER THE WORKMEN'S COMPENSATION ACT, 1925, for the County Court Districts of Henley-on-Thames, Windsor (Circuit No. 39), Kingston-on-Thames, Wandsworth (Circuit (No. 45), Woolwich, Southwark (Circuit No. 47), Epsom, Guildford (Circuit No. 48), Croydon (Circuit No. 56). Applications to the Under-Secretary of State, Home Office (Industrial Division), Cleland House, Page Street, S.W.1, by March 3.

APPOINTMENTS

EXAMINING FACTORY SURGEONS.—D. K. Crawford, F.R.C.S., for the Berkhamsted District (Hertfordshire); W. F. Mangan, M.B., B.Ch., for the Liverpool (Garston) District (Lancashire); H. S. Cunningham Smith, M.R.C.S., L.R.C.P., for the Brixham District (Devonshire).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

BIRTH

CRAWSHAW.—On January 25, at Omagh, Co. Tyrone, to Barbara, wife of Lieut. G. R. Crawshaw, R.A.M.C., a son.

DEATH

ALLAN.—On January 28, 1941, at "Ingledene," 39, The Avenue, Roundhay, Leeds, in his 88th year, James Allan, M.A., M.D.Aberd., D.P.H.Camb., late Medical Superintendent, St. James's Hospital, Leeds.

A resolution was passed by the executive committee of the Socialist Medical Association at its last meeting stating that it "considers that the imposition of a Purchase Tax on non-proprietary drugs and medicines is detrimental to the health and well-being of the nation. It calls upon the Government to abolish the Purchase Tax on the following items provided that no trade name or proprietary right is claimed in connexion with them: (*a*) all the preparations of the *British Pharmacopoeia* and the *British Pharmaceutical Codex*; (*b*) all other drugs and medicines if supplied on the prescription of a qualified practitioner."

PREVENTION OF GAS-GANGRENE INFECTIONS IN EXPERIMENTAL WOUNDS BY LOCAL APPLICATION OF SULPHONAMIDE COMPOUNDS AND BY SERA

BY

FRANK HAWKING, D.M.

(From the National Institute for Medical Research, Hampstead)

This paper describes an experimental investigation into the possibility of using sulphonamide compounds to prevent the development of gas gangrene in wounds. Briefly, experimental wounds were made in guinea-pigs: one of the compounds was applied, a massive inoculation of *Cl. welchii*, *Cl. septique*, or *Cl. oedematiens* was introduced, and then the wound was closed, the efficiency of the treatment being indicated by the survival or death of the animal. This procedure involves two main problems: the activity of these compounds against anaerobes, and the value of treatment by local application instead of general systemic administration.

Literature

(*a*) *Activity of Sulphonamide Compounds against Anaerobes.*—The earliest reports on this subject appear to be those of Long and Bliss (1937) and Domagk (1937), who found that sulphanilamide and uleron would save mice from infection with *Cl. welchii*. Bohlman (1937) treated three cases of gas gangrene with sulphanilamide, and obtained a prompt response. More recently Stephenson and Ross (1940) have investigated the effect of these compounds in mice, the bacilli being injected intraperitoneally or intramuscularly and the drug being given orally. In the case of *Cl. welchii* they found that sulphanilamide and sulphapyridine would protect many of the animals. With *Cl. septique* sulphanilamide had little action, but sulphapyridine in large doses saved 50% of the animals. With *Cl. oedematiens* neither sulphanilamide nor sulphapyridine had any effect. In most cases treatment with serum was better than treatment with drugs, but the best results were obtained by a combination of the two. Henderson and Gorer (1940) obtained roughly similar results. McIntosh (at a recent conference) reported that, in mice, sulphathiazole was the most active compound, whether given generally or locally; but infections with *Cl. oedematiens* were difficult to influence. Burton, McLeod, McLeod, and Mayr-Harting (1940) found that the anaerobes are relatively insensitive to sulphanilamide and sulphapyridine *in vitro*, but highly sensitive to *p*-nitrobenzene-sulphonamide. Fuller (personal communication) finds that *in vitro* the anaerobes are most sensitive to sulphathiazole, less to sulphapyridine, and least to sulphanilamide.

(*b*) *Local Application of Sulphonamides to Wounds and Similar Lesions.*—The earlier literature on this subject contains a number of clinical papers, often with little evidence in support of their statements—e.g., Jaeger (1936), Tiling (1936), Brown (1937), Merz (1937), Bosse and Bosse (1939), Childrey (1939), and Smith (1940). Much more convincing is the paper by Jensen, Johnsrud, and Nelson (1939). They treated 41 cases of compound fracture with 5 to 15 grammes of sulphanilamide applied locally, combined with the usual surgical measures. The infection rate had previously been about 27%, but in their series only two cases (5%) became infected—due in both cases to having been re-compounded. The concentration in serum oozing from the wounds was 250 to 660 mg. per 100 c.cm. (the maximum solubility being about 800 mg.). They found also that the local application of sulphanilamide promoted the healing of staphylococcal infections of experimental fractures in guinea-pigs. Later papers have tended to confirm their findings. Thus Sézary (1939) reports that soft chancres and phagedaenic ulcers heal rapidly if they are dressed with powdered sulphanilamide, and Riou (1939) confirms this, using a paste containing 10% sulphapyridine. Mayo and Miller (1940) have recommended a saturated solution of sulphanilamide in saline for the irrigation of wounds following resection of the rectum; and Herrell and Brown (1940) have obtained encouraging results by applying a mixture of 3 grammes of sulphanilamide in 100 ml. saline to a variety of wounds, including infected thoracic and abdominal cavities. Wardle (1940), Jeffrey (1940), and Eisenhammer (1940) have found that the insertion of sulphanilamide into the knee-joint cavity causes no reaction. Chorine (1940) obtained very good results when 31 wounds were dressed with sulphanilamide. Levaditi, Bréchot, Gérard-Moissonier, and Tournay (1940) applied sulphanilamide or prontosil soluble to 12 older wounds infected with streptococci: marked clinical improvement was obtained in every case, and 5 of the wounds became free from these organisms. Colebrook (1940b) has similarly found that the local application of sulphanilamide will remove streptococcal infections from wounds. During recent months the application of sulphonamide compounds to wounds has been discussed by Colebrook (1940a), Jeffrey (1940), Buxton (1940), and others; unfortunately the disturbed conditions of war have so far prevented the collection of a satisfactory series of treated cases, complete with adequate controls.

On the experimental side the local application of sulphonamides seems to have attracted little attention at first apart from an unsuccessful attempt by Nicholson (1938) to treat streptococcal empyema in rabbits by intrapleural injections of prontosil soluble. With the outbreak of war, work was started in France. Nitti (1939) made experimental wounds in the dorso-lumbar muscles of rabbits. He applied a small compress of gauze soaked in a culture of streptococci, and on top of this about 1 gramme of sulphanilamide, the skin being finally closed. The controls died in twenty-four to forty-eight hours. Treated animals were still alive forty-eight hours later; the wound was reopened, the gauze removed, and new sulphanilamide added; under these circumstances most of the treated rabbits survived. The local application of sulphanilamide to a wound never caused irritation, its toxicity was low, and it was all absorbed and eliminated in forty-eight to sixty hours. Legroux (1940) used a technique closely resembling that of the present paper (to which it served as a pattern). His main experiments were similar to those of Nitti. He also made studies in guinea-pigs, the wound being dusted with sulphanilamide and infected by the insertion of a piece of cloth soaked in a culture of *Cl. welchii* or *Cl. histolyticum*. Controls died in two to three days. Animals which had received sulphanilamide died after four to seven days; but if the wound was reopened, the cloth removed, and new sulphanilamide added they survived. Delay of the treatment for more than one hour after insertion of the culture or administration of the compound by mouth instead of by local application resulted in death of the guinea-pigs. In similar experiments with *Cl. tetani* sulphanilamide produced only a slight prolongation of life.

Experimental

The experimental technique used in the present work was based on that of Legroux (1940). Under full anaesthesia with chloroform, an incision was made on the inside of the thigh of a guinea-pig (weight 200 to 250 grammes). The muscles anterior and posterior to the femur were well crushed with Spencer Wells forceps, the main blood vessels being spared. The drug (0.2 gramme) was then spread over and into the crushed muscle. A piece of cloth 15 by 15 mm. soaked in the bacterial culture was placed on top of the muscle and the wound was tightly closed by continuous suture. After three days, in animals which survived, the wound was reopened under an anaesthetic, the cloth was removed, and fresh drug (0.2 gramme) was applied, the skin being resutured loosely. The culture used was a twenty-hour growth in meat broth containing glucose. The cloth took up about 0.1 gramme of the fluid. Numerous control experiments showed that even four times this volume of fluid, sterilized by filtration, did not contain enough toxin to kill a guinea-pig. The density of the culture was estimated roughly by comparing its capacity with that of standard Brown's tubes. In order to avoid error due to abnormal strains of organisms numerous different strains were examined. The origin of these is as follows.

Cl. welchii :

A.5 : isolated May, 1940, from compound fracture ; no gangrene
S.R 12 : " 1915, " fatal gas gangrene
Corcoran : " 1939, " peritonitis
A 7 : " " 1940, " non-fatal gas gangrene
S.107 : animal origin, used as toxin-producer at Marburg for many years (Henderson, personal communication).
Rosher : isolated, 1940, from puerperal gas gangrene
Hudson : " June, 1940, from wound without gas gangrene
Barnetson : " " " " wound of chest ; empyema
Constantine : " " " " non-fatal gas gangrene

Cl. septique :

V.S.14 : Pasteur III, from Nat. Coll. type cultures—Type I
V.S.20 : isolated 1914–18—Type III
V.S.A.48 : " June, 1940, from non-fatal case of tetanus
V.S.A.52 : " " " " " osteomyelitis and ? gas gangrene

Cl. oedematiens :

No. 3 : from Nat. Coll. type cultures (140, No. 3908). More than 11 years old
Cossard : ditto, isolated, 1918, from fatal gas gangrene

In most of the experiments the control untreated animals died in twenty-four hours, and showed the typical appearances of purplish subcutaneous oedema spreading out from the wounded thigh and involving much of the abdomen and thorax. Bacilli were present in the oedema fluid, in the peritoneum, and often in the heart blood taken shortly before death. Treated animals which died in the first two days showed post-mortem appearances similar to the controls. In a few cases in which the invasiveness of the organisms and the restraining influences (defence mechanisms plus drug) were approximately balanced a spread of gangrenous oedema took place over part of the abdomen, the skin being sodden, foul, and depilated ; some of the affected animals died in four to seven days ; others gradually recovered, the oedematous skin becoming hard, dry, and wrinkled. Some treated animals which survived the initial infection developed a large ulcer in the injured groin, with secondary infections of all kinds ; these ulcers often penetrated into the abdomen, eventually causing death between the seventh and sixteenth days. The appraisal of such deaths is difficult, but fortunately they were few in number. All animals were observed for thirty days ; but for the purpose of statistics we have taken an arbitrary period of ten days (which includes almost all the deaths), and only those occurring within that period have been shown in the protocols. In order to give a concise quantitative indication of the prolongation of life occurring among the non-survivors, an index figure (the guinea-pig-day index) has been calculated by adding up the number of guinea-pigs in the group which were alive on each of the first ten days after the initial operation and expressing this figure as the percentage of the maximum number of guinea-pig-days possible under this system—i.e., 60 in a group of 6 guinea-pigs. With *Cl. oedematiens*, however, it happened several times that the initial wound healed perfectly and the animal appeared quite well until about the fifteenth day, when it died with the post-mortem appearances typical of this infection (i.e., massive gelatinous oedema of the subcutaneous tissues). Hence, with *oedematiens* the survival figures and the "guinea-pig-day index" are based on a period of twenty days.

The reopening of the wounds on the third day afforded an opportunity for inspection. In treated animals which would survive completely the wounds usually contained a trace of thin fluid ; pus was slight or absent. Parts of the damaged muscles were white and necrotic, but often the sloughs were surprisingly small in extent ; the rest of the muscles was vascular and bled easily. By this time sulphanilamide had all been absorbed, but sulphapyridine and sulphathiazole were found, in the appropriate animals, as small flattened masses. The action of the compounds is essentially bacteriostatic, not bactericidal. Smears made from the wounds on the third day invariably demonstrated great numbers of clostridia, which could readily be cultivated on appropriate media.

Preliminary experiments, made by inserting sulphanilamide, sulphapyridine, and sulphathiazole in solid form subcutaneously or intraperitoneally, showed that these compounds are comparatively harmless to the body tissues. By the naked eye no signs of local inflammation are seen ; microscopically a diffuse infiltration by polymorphs and monocytes is found, but this is not much more than would occur with any foreign body. Sodium sulphapyridine, however, is very irritant, being strongly alkaline. Similar conclusions concerning the innocuousness of sulphanilamide have been reached by Russell and Falconer (1940b), by Key and Burford (1940), and by Glynn (unpublished).

Prophylactic Action of Sulphonamide Compounds

In these experiments sulphanilamide, sulphapyridine, and sulphathiazole were used, and also a mixture (designated the "mixture" for brevity) of sulphanilamide 2 parts and sulphathiazole 1 part. It was hoped that this would combine the merits of the two components, sulphathiazole being the most potent and sulphanilamide being much cheaper and also more soluble and diffusible, which might be advantageous in the earliest stages of wound treatment. The power of the different compounds to prevent infection under these conditions is shown in Table I, in which the results of different experiments are grouped together. In addition to a variation from one experiment to another, depending presumably on the virulence of the strain used, the number of bacilli introduced, the amount of toxin present, etc., the findings vary with the different organisms employed, so that it is necessary to consider each organism separately.

TABLE I.—*Protection of Guinea-pigs against Gas-gangrene Infections by Local Application of Sulphonamide Compounds.* (The figures in brackets in each column represent the "guinea-pig-day" index.")

Strain	Survival of Animals				
	Sulphanilamide	Sulphapyridine	Sulphathiazole	Mixture	Controls
(*a*) *Cl. welchii :* Corcoran & Rosher	9/12 (86)	7/12 (80)	11/12 (93)	5/6 (88)	0/12 (3)
S.107 and A.7 ..	—	2/12 (21)	9/12 (77)	—	0/12 (1)
S.107 and S.R.12..	—	—	3/6 (50)	—	0/6 (0)
S.R.12	—	3/6 (67)	—	—	0/6 (0)
S.R.12	4/6 (73)	4/6 (82)	—	—	0/6 (3)
Hudson and Barnetson, plus contaminants* ..	3/12 (33)	1/12 (19)	5/12 (70)	*8/12 (79)	0/12 (0)
Totals	16/30 (62) (53%)	17/48 (48) (35%)	28/42 (73) (67%)	13/18 (81) (72%)	0/54 (1) (0%)
(*b*) *Cl. septique* V.S.20, V.S.A.48, and V.S.A.52 ..	0/23 (7) (0%)	9/24 (41) (38%)	18/24 (84) (75%)	7/17 (47) (41%)	0/24 (0.5) (0%)
(*c*) *Cl. oedematiens* No. 3 and Cossard	5/18 (41) (28%)	1/18 (10) (6%)	6/18 (38) (33%)	1/6 (21) (17%)	2/18 (14) (11%)

* In these two experiments the cultures of *Cl. welchii* were mixed with cultures of *B. proteus*, *B. coli*, *Ps. pyocyanea*, and *Cl. sporogenes* to imitate the conditions of a grossly contaminated wound.

(*a*) *Cl. welchii.*—The culture usually contained over 10⁹ bacilli per ml., and dilutions of 1 : 10,000 killed control animals when introduced into the wounds. Nevertheless the compounds usually saved a large proportion of the treated animals; and the life of non-survivors was often prolonged, as is shown by the "guinea-pig-day index." Since some of the experiments did not include all the three compounds, a simple inspection of the total survivals in each column does not provide an accurate picture of their relative potency; it is necessary to consider only those experiments in which each of the pair under comparison was present. Then, taking the three different pairs, consideration of the mixture being postponed, the following ratios of potency are obtained:

	Survivals	Average Guinea-pig-day Index
Sulphanilamide : sulphapyridine .	16 30 . 12 30	60 56
Sulphapyridine : sulphathiazole .	10 36 : 25 36	40 80
Sulphanilamide : sulphathiazole .	12 24 : 16 24	60 80

Accordingly, sulphathiazole is distinctly more active against *Cl. welchii* than sulphapyridine, while sulphanilamide occupies an intermediate position. Another basis for comparison may be obtained by taking the totals of three experiments in which all four substances were tested and the infections in the wounds were especially virulent (not shown separately in table): the survivals were: controls 0 18, sulphapyridine 5 18, sulphanilamide 8 18, sulphathiazole 10 18, and "mixture" 13/18. The order of activity was the same as before, apparently the "mixture" was equal or superior to sulphathiazole, but with this number of animals only a tentative conclusion is possible.

(*b*) *Cl. septique.*—With this organism the cultures usually contained about 10⁹ bacilli per ml. Sulphathiazole was again the most potent compound (survivals 75%): sulphapyridine was inferior (38%): sulphanilamide had practically no action against this organism (0%): while the "mixture" had an effect similar to that of sulphapyridine (41%).

(*c*) *Cl. oedematiens.*—The culture usually contained over 10⁹ bacilli per ml.; dilutions of this amount by 1,100 often failed to kill control animals when introduced into the wounds. The survivals after sulphanilamide and sulphathiazole were somewhat more numerous than those among the controls, but not significantly so: and life was often prolonged, the differences between the "guinea-pig-day indices" being just great enough to be statistically significant (probability, 1 : 20). Probably sulphathiazole possesses a small prophylactic activity against infection with *Cl. oedematiens*, but it is much less than that against *Cl. welchii* and *Cl. septique*.

Controls.—In order to be sure that the survival of the treated animals was due to the specific action of the sulphonamide compounds and not to a non-specific action possessed by other powders a series of comparisons was made with various neutral compounds—namely, sodium chloride, calcium carbonate, and urea. As was expected, calcium carbonate or urea had no power at all to prevent infection, while sodium chloride appeared positively to favour its development.

Comparison with Other Anti-bacterial Compounds

Brief tests were also made on a number of other anti-bacterial compounds. So far as this short investigation went soluseptasine and prontosil soluble were inferior to sulphathiazole, possessing little or no activity. The survivals after proseptasine and prontosil rubrum were not much different in number from those after sulphathiazole; but the clinical condition of the wounds (many of which showed a limited spread of the gangrenous infection) was definitely worse. None of these four compounds seemed promising enough to warrant more extended investigation. A number of animals were treated with nitrobenzene-sulphonamide; the results indicated that this compound is highly toxic, and that *in vivo*, under these experimental conditions, its activity is no greater than that of sulphathiazole. Experiments were also made with proflavine on account of the recommendations which this compound has received as a non-irritant antiseptic for wounds in recent papers—e.g., Russell and Falconer (1940a). Applied in strong concentration proflavine will certainly prevent infection of a wound by anaerobes subsequently inserted. On reopening at the third day, wounds which had been treated with 1% or 0.1% solutions showed fairly healthy tissues and only small numbers of bacilli. Nevertheless, in view of the mediocre results obtained with acridine compounds in the last war (presumably through inability to reach bacteria situated inside the tissues), the usefulness of proflavine as a wound antiseptic is probably limited.

Comparison of Local and Systemic Treatment

Guinea-pigs treated locally were compared with those which received sulphathiazole intraperitoneally, given as a suspension in water, about two hours before the wound was made. The dose was 0.2 gramme per guinea-pig of 200 to 250 grammes. This was about the maximum tolerated dose for infected animals: healthy animals would stand 0.4 or sometimes 0.8 gramme intraperitoneally, but infected ones were apt to show toxic symptoms after 0.4 gramme. In any case much of the drug was not absorbed during the first two days, but was deposited as small masses throughout the abdomen. (When sulphonamides are inserted into a wound, however, the toxicity depends more upon the rate of absorption than upon the total quantity injected: under these circumstances guinea-pigs will tolerate over 1 gramme of sulphathiazole.) The results of this series are given in Table II. The difference

TABLE II.—*Comparison of Activity of Sulphathiazole in Protecting Guinea-pigs against Gas-gangrene Infections when Applied Locally and when Administered Systemically by Intraperitoneal Injection.* (The figures in brackets in each column represent the "guinea-pig-day index.")

Infection	Survival of Animals		
	Local Treatment	Intra-peritoneal Treatment	Controls
Cl. welchii (4 strains) ..	14 24 (74)	5 14 (46)	0 24 (0)
Cl. septique (2 strains) ..	7 12 (67)	0 3 (3)	0 12 (0)
Totals	21 36 (71) (55%)	5 22 (30) (23%)	0 36 (0) (0%)

in efficacy between the two treatments is greater with *Cl. septique* than with *Cl. welchii*; but, taking the two together, it is seen that while local treatment saved 58% of the animals, systemic (intraperitoneal) treatment, even if given two hours previously, saved only 23%. Thus, although systemic treatment has some value it is inferior to local treatment under these experimental conditions.

Effect of Delaying Local Treatment

The effect of delaying local treatment was studied in four experiments with *Cl. welchii* and one with *Cl. septique*. In these animals the wound was made in the usual manner and the cloth soaked in culture inserted. After two hours or six hours the incision was reopened, the cloth lifted out, the wound packed with 0.2 gramme of sulphathiazole, and the cloth replaced. Taking the series as a whole it was found that when treatment was immediate 20 out of 30 animals survived (67%): when the treatment was delayed two hours 3 out of 15 animals survived (26%): and when treatment was delayed six hours none out of 6 animals survived. None of the 30 controls survived. Thus a delay of even two hours greatly reduced the efficacy of the treatment.

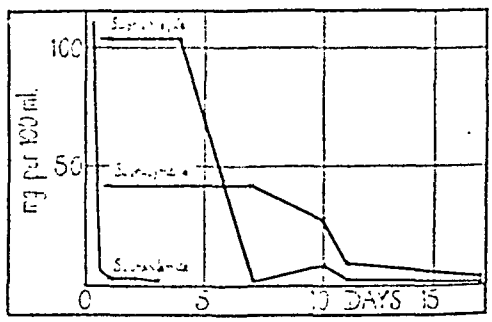
Diffusion of Sulphonamide Compounds from Wounds

The time required for absorption of the compounds from wounds and the concentrations which occurred in adjacent tissues were studied in two ways. First, pre-

liminary experiments were made to see how far the high concentration present in the wound cavity extended through the adjacent tissues. A transverse incision was made into the lumbar muscles of rabbits (weight about 1 kg.), and 0.25 gramme of sulphanilamide, made into a thick paste with water, was inserted. The fascial covering of the muscle was carefully sutured together and any extruded sulphanilamide wiped away. The skin wound was then closed. Six or twenty-four hours later the rabbits were killed, and transverse slices of the lumbar muscles about 0.5 cm. thick were taken at various distances from the wound; blood from the heart and pieces of muscle from the opposite thigh were also taken as controls. The concentration of free sulphanilamide in the various specimens was estimated by the method of Marshall and Litchfield (1938). The results of an experiment comprising six rabbits are given in Table III. At six hours

TABLE III.—*Diffusion of Sulphanilamide from an Uninfected Wound in Rabbit's Muscle*

Time	Concentration of Free Sulphanilamide (mg. per 100 c.cm.)				
	Sides of Wound	1-2 cm. Away	4-5 cm. Away	Control Muscle (Opp. Thigh)	Blood
6 hours ..	105+	16.2	2.6	2.2	0.7
	122+	4.9	5.0	3.8	1.3
	109+	7.0	3.2	5.1	1.8
Average ..	112+	9.4	3.6	3.7	1.3
24 hours ..	0.12	0.2	0.13	0.1	0
	0.3	0.1	0.13	0.13	0
	0.3	0.13	0.6	0.1	0
Average ..	0.24	0.14	0.29	0.11	0



solid sulphanilamide was still present in the wound, but after twenty-four hours practically all the sulphanilamide had disappeared. At six hours the concentration in muscle 4 to 5 cm. away from the wound was no greater than that in muscle elsewhere; muscle 1 to 2 cm. away from the wound appeared to have a higher concentration, but part of this may have been due to leakage from the wound between the surface of the muscle and its fascial covering. At any rate, the higher concentration did not extend to any great distance from the wound. The fact that the concentration of free sulphanilamide in the control muscles of these animals was higher than that in the blood was unexpected, but similar findings were obtained in confirmatory experiments.

The second series of experiments was made to investigate the fate of sulphonamide compounds in the experimental wounds of guinea-pigs described above. The wounds were formed in the standard manner, and 0.2 gramme of the various compounds was inserted; they were then closed without inserting the piece of cloth. The animals were killed at suitable intervals, the reopening of the wound on the third day being omitted. The muscles of the wounded thigh, the muscles of the opposite thigh (control), and blood from the heart were taken for chemical estimation. The results of these experiments are given in Table IV, and the average concentration of the various compounds in the wound is depicted graphically in the figure. Sulphanilamide is rapidly absorbed, so that its influence in the wound is probably slight after the first twenty-four hours. Solid sulphapyridine persists in the wound for seven to ten days; its solubility in 0.85% saline at 37° C. is 42 mg. per 100 ml. Solid sulphathiazole persists in the wound over four days; during this period its concentration in the wound fluids will be higher than that of sulphapyridine, owing to its greater solubility—namely, 104 mg. per 100 ml. in 0.85% saline at 37° C. (Ewins, personal communication). This greater solubility may be a partial explanation of its greater therapeutic potency (described above), but part also is due to its more powerful bacteriostatic action against anaerobes, which can be demonstrated *in vitro* (Fuller, personal communication). By a suitable mixture of the more diffusible sulphonamides—e.g., sulphanilamide and sulphathiazole—

TABLE IV.—*Concentration of Sulphonamide Compounds in Guinea-pigs (Weight 200 to 250 grammes), following Insertion of 0.2 gramme of Drug into Experimental Wounds*

with the less diffusible ones—e.g., sulphapyridine and proseptasine—it would be possible to produce a combination which would embody the advantages of both types—namely, the high initial concentration of the former and the prolonged action of the latter. However, so far as infection of wounds with *Cl. welchii* or *Cl. septique* is concerned, it is probably the initial period which is the important one: if the organisms can be held in check for the first two to four days it is less likely that gas gangrene will develop.

Comparison of Drug Treatment with Treatment by Antisera

A number of the animals were also treated by antisera. The wound was made according to the standard technique, the antiserum being given by intraperitoneal injection shortly before or after the operation; on the third day the wound was reopened to remove the cloth, and the dose of antiserum was repeated. It is impossible to reproduce human conditions exactly, since among other difficulties there is no agreement as to what is an equivalent dosage of a serum for a guinea-pig and for a man. Two series of experiments were made. In the first (Table V) use was made of three concentrated monovalent sera kindly supplied by Burroughs Wellcome and Co.: (1) prepared against *Cl. welchii*, S.R.12 (Type A)—4,000 units of antitoxin per ml.; (2) prepared against *Cl. septique*, V.S.14—6,000 units of antitoxin per ml.; (3) prepared against *Cl. oedematiens*, No. 3—9,000 units of antitoxin per ml. The doses given are probably much larger than is necessary. With *Cl. welchii* the antiserum gave complete protection in one case and no protection in the other; it is not clear whether this was due to the different strain used or to the delay in administering treatment. With *Cl. oedematiens* all the animals treated by serum survived except for 2 which died seventeen days after the second dose:

TABLE V.—*Comparison of Activity of Sulphathiazole in Protecting Guinea-pigs against Gas-gangrene Infections with that of Specific Monovalent Sera (Antitoxin)*

Infection		Antitoxin		Survival of Animals		
Strain	Bacilli per ml. × 10⁸	Dose Units	Time	Antitoxin	Sulphathiazole	Controls
Cl. welchii, S.107, incompletely washed	23	1,000 i.p.	½ hr. before	3/3 (100)	5/6 (83)	0/6 (0)
Cl. welchii, A.7, incompletely washed	·	1,000 i.p.	2½ hrs. after	0/3 (0)	4/6 (67)	0/6 (0)
Cl. septique, V.S.14, washed	<0.5	500 i.v. 1,500 locally	Just before Just before	3/3 (100) 3/3 (100)	3/3 (100) (sulphapyridine)	1/3 (40)
Cl. oedematiens, No. 3, washed	<0.5	9,000 i.p.	1½ hrs. before	5/6 (99)	2/6 (43)	1/6 (20)
Cl. oedematiens, No. 3, incompletely washed	1.8	1,000 i.p.	½ hr. after	2/3 (99)	4/6 (67)	1/6 (18)

presumably, if treatment had been continued at five-day intervals these deaths would not have occurred.

The second series of experiments was designed to imitate more closely the conditions in a casualty department when a small dose of antitoxin is given prophylactically against an infection of unknown identity. A commercial polyvalent serum was taken containing *Cl. welchii* antitoxin 3,000 units, *Cl. septique* antitoxin 1,500 units, and *Cl oedematiens* antitoxin 1,000 units per ml. This was injected intraperitoneally at the time of the operation or at various subsequent periods. Many different strains of clostridium were used to infect the wound; in some experiments two different strains were inserted simultaneously (Table VI). The most striking features are the

TABLE VI.—*The Activity of a Polyvalent Serum (Antitoxin) in Protecting Guinea-pigs against Gas-gangrene Infections*

Infection		Dose of Serum (ml.)	Survival of Animals

comparative success of this antiserum in protecting the animals against *Cl. oedematiens* (against which drugs are ineffective) and its failure against *Cl. septique* (for which sulphathiazole is potent). Against *Cl. welchii* the results varied according to the different strains. Delay in the treatment in one case (Hudson and Barnetson) annulled its efficacy. Since the serum was administered intraperitoneally in all these animals there may have been some delay before a sufficient amount was absorbed into the blood stream and carried to the wound. A more detailed discussion of these results with serum is beyond the scope of this paper.

Discussion

The information obtained experimentally about the prevention of gas gangrene in wounds by the local application of sulphonamide compounds may be briefly summarized thus: Sulphonamides will protect against *Cl. welchii* and *Cl. septique*, but only to a slight extent against *Cl. oedematiens*; the most potent compound under these experimental conditions is sulphathiazole; treatment by local application is more effective than systemic treatment; delay in applying the treatment reduces its value considerably. These results concerning the superior potency of sulphathiazole and the difficulty of combating infections with *Cl. oedematiens* agree with the experience obtained in mice by McIntosh (above) and by Stephenson (personal communication). The findings are more favourable than those originally reported by Legroux, although his infections appear to have been less severe, since his controls lived for two to three days while those in the present work died in twenty-four hours.

The fundamental purpose of all this research was to obtain information as to how far the insertion of sulphonamide compounds into wounds would be a useful addition to the surgical methods now employed. Such insertion could occur under three different conditions: (1) On the battlefield, with little disturbance of the wound, for the purpose of delaying the development of infection in cases which will not reach a surgeon for a long period or in which surgical treatment must be postponed on account of shock (Buxton, 1940). (2) In the operating theatre, after débridement, etc. (possibly followed by plaster-of-Paris), for the purpose of inhibiting the development of organisms (anaerobic or pyogenic) which cannot be excised. (3) At subsequent dressings of wounds (this will probably be directed mainly against streptococci).

The experiments were designed to resemble the first two of these groups: but admittedly the conditions are somewhat artificial, and a simple transference of the conclusions to human cases is not quite legitimate. However, they do suggest strongly that treatment along these lines would be beneficial to casualties. Such treatment can be recommended the more confidently since the compounds are innocuous and non-irritant. A number of air-raid casualties and street accidents have been treated in this way at adjacent hospitals, and the results have been extremely satisfactory, even in wounds with a heavy initial contamination.

So far as gas gangrene is concerned, the treatment may be expected to be of value chiefly as a prophylactic measure, and much less so as a therapeutic one: and clearly it should be a supplement to proper surgical measures and not a substitute for them (unless they are not available). In dealing, however, with a condition such as gas gangrene, which although often fatal has a low and irregular incidence, it will be very difficult to get reliable evidence about the value of such prophylactic treatment in human cases. At a recent conference the incidence of gas gangrene among air-raid casualties was given as 5 in 1,000 (0.5%) in one town and 5 in 187 (2.7%) in a hospital in another. Assuming an incidence of 1.5%, and that a prophylactic treatment applied to all patients caused a diminution by 80%—that is, an incidence rate of 0.3%—then to get the barest significant result (probability of chance, 1:22), and using the strictest precautions to obtain identical patients in both series, two sets of cases each about 320 in number would be required. Under actual clinical conditions, even if great care were exercised, a much larger number would be needed. Consequently an assessment of the value of this treatment by purely clinical methods will take a long time, even with the abundance of material which war unfortunately provides.

Finally, a word on the prophylaxis of gas gangrene by means of serum—although this question lies mainly outside the scope of the present paper. Since serum and

drug supplement one another, the ideal procedure for *general* use should include both. In special hospitals, however, where *large* numbers of casualties are seen, it would be desirable to build up three series of cases—treated respectively with drug, with serum, and with neither (controls)—so that the clinical assessment on these procedures (discussed above) could eventually be made.

Summary

Experimental wounds (with crushed muscle and the presence of a foreign body) were made in guinea-pigs, and large numbers of gas-gangrene organisms were inserted; untreated animals died within twenty-four hours.

Application of sulphonamide compounds to the wounds at the same time as insertion of the organisms saved a large proportion of the animals infected with *Cl. welchii* and with *Cl. septique*, but it had only slight influence upon infections with *Cl. oedematiens*. Sulphathiazole was the most effective compound to use in all cases; sulphanilamide was superior to sulphapyridine in preventing infection with *Cl. welchii*, but it had practically no activity against *Cl. septique*.

Local application of sulphathiazole to the wound was more effective in preventing infection than systemic administration by intraperitoneal injection. Delay of two hours in applying the treatment greatly reduced its effectiveness.

Sulphanilamide is absorbed from wounds very quickly (in less than twenty-four hours), giving a high but transitory concentration in the fluids of the wound (1,500 mg. per 100 c.cm.); sulphapyridine is absorbed slowly from the wound (seven to ten days) and its concentration in the wound is low (42 mg.) but prolonged; sulphathiazole occupies an intermediate position, being absorbed in about five to six days and producing a concentration of about 104 mg.

The development of the infection in these wounds could also be prevented by administration of sera (antitoxin). Monovalent sera specific for *Cl. welchii*, *Cl. septique*, or *Cl. oedematiens* protected the guinea-pigs against these organisms respectively. A commercial polyvalent serum gave protection against *Cl. welchii* (most strains) and *Cl. oedematiens*, but not against *Cl. septique*.

It is recommended that war wounds should be protected against the development of gas gangrene by the local application of sulphonamide compounds together with injection of antitoxin.

Grateful acknowledgments are due to Dr. R. Cruickshank, Prof. A. A. Miles, and Dr. H. J. Parish for kindly supplying the strains; to Messrs. Bayer Products, Ltd., Burroughs Wellcome and Co., and May and Baker Ltd. for kindly providing the compounds; to Col. L. Colebrook, Dr. A. J. Ewins, Dr. A. T. Fuller, Dr. D. W. Henderson, and Miss D. Stephenson for much helpful advice and information; and to Miss M. Kuck for technical assistance and co-operation.

ACTIVATION OF THROMBOPLASTIN PREPARATIONS BY HAEMOLYSIS AND BY LECITHIN

BY

ANDREW CROSBIE

AND

HAROLD SCARBOROUGH, M.B., D.Ph.

Crichton Research Scholar

(From the Clinical Laboratories, the Royal Infirmary, Edinburgh)

During an investigation into the effect of storage on the prothrombin index of blood (Crosbie, Scarborough, and Thompson, 1941) one of us (A. C.) observed that the presence of haemolysis in the plasma was often associated with a decreased coagulation time as determined by Quick's technique. This acceleration was more pronounced when Russell-viper venom was used instead of brain extract as the source of thromboplastin as recommended by Fullerton (1940). While seeking an explanation for this phenomenon we read the letter of Hobson and Witts (1940) stating that they had confirmed the original observation of Trevan and Macfarlane (1936–7) that the coagulant action of Russell-viper venom was potentiated by the addition of lecithin. It occurred to us that the accelerating effect of haemolysis might be due to the liberation of lecithin into the plasma from the ruptured envelopes of erythrocytes. In this paper, a summary of which has already appeared (Crosbie and Scarborough, 1941), we give an account of our results. While the paper was being prepared for the press Witts and Hobson (1940) published their own observations, which demonstrated that lecithin used in association with Russell-viper venom produces an acceleration of the coagulation time as determined by Quick's method, and suggest that the adjuvant action of lecithin may be used in the elucidation of three types of haemorrhagic tendency.

Material and Methods

None of the subjects from whom blood was taken for this investigation had any form of haemorrhagic disease. Apart from a few patients with jaundice, to whom specific reference is made, the subjects either attended the out-patient department for minor complaints or were normal healthy adults. All coagulation times were determined by the method of Quick (1936), except that snake venom or venom plus lecithin replaced brain extract as the source of thromboplastin.

4.5 c.cm. of venous blood withdrawn with the minimum of trauma was added to 0.5 c.cm. of M/10 potassium oxalate or, in some cases, to 0.5 c.cm. of 3.8% sodium citrate. In order to reduce cell damage to the minimum, centrifugalization was avoided and plasma was obtained by allowing the specimens to stand overnight in a refrigerator at 2° to 5° C. This treatment does not affect the coagulation time as determined by Quick's original method with brain extract as the source of thromboplastin. 0.1 c.cm. of plasma was pipetted into a clean dry test-tube (7 × 70 mm.) in a water bath at 37° C. and mixed with 0.1 c.cm. of thromboplastin preparation. Immediately 0.1 c.cm. of M/40 calcium chloride was added and the coagulation time at 37° C. was determined in seconds.

Three sources of thromboplastin were used:

1. Brain Extract.—This was prepared according to the method of Quick, but from human instead of from rabbit brain as originally recommended.

2. Russell-viper Venom (stypven, B. W. and Co.).—Two different batches of material were used. They did not differ appreciably in activity. A dilution of 1 in 10,000

(0.1 mg. in 1 c.cm.) proved satisfactory: higher dilutions were found to give increased coagulation times.

3. Russell-viper Venom plus Lecithin.—The preparation of lecithin used was a 10% alcoholic solution of ovolecithin (*B.P.C.*). This substance is by no means pure. It is prepared from dried egg-yolk by extraction with alcohol and precipitation by acetone. According to the 1934 *Codex*, "when so prepared the product consists of a mixture of true lecithin and a similar compound, kephalin." A large number of different lecithins occur naturally, and lecithins are present in the membrane of human erythrocytes to the extent of 3.25 to 5.75 mg. per c.cm. of cells (Ponder, 1934). The particular preparation of ovolecithin used by us was equally active over a wide range of dilutions, and we accordingly adopted the dilution previously suggested by Hobson and Witts (1940).

Haemolysis was produced mechanically — "slight" haemolysis by gentle shaking for one minute, and "marked" haemolysis by vigorous shaking for two minutes. Haemolysed plasma was then obtained by centrifuging.

Results

The following points emerge from a consideration of Table I, which illustrates the effect of haemolysis on the coagulation time of both oxalated and citrated plasma with either brain extract or 1 in 10,000 Russell-viper venom as the source of thromboplastin:

1. The coagulation time is reduced by haemolysis, the reduction being greater with "marked" than with "slight" haemolysis.

2. The acceleration of the coagulation time is more pronounced when venom instead of brain extract is the source of thromboplastin. It is indeed possible that the differences obtained with brain extract are without significance.

3. In the absence of haemolysis the observations show a fairly wide scatter. This scatter is reduced by "slight" haemolysis. After "marked" haemolysis there is extraordinary *uniformity throughout the series, especially when venom is the* source of thromboplastin. Associated with this regularity of the final result there is wide variation in the extent to which the coagulation time is reduced by haemolysis.

4. Viper venom, in the absence of haemolysis and without lecithin, is a more potent source of thromboplastin than is brain extract. It should be pointed out, however, that Quick regularly obtains coagulation times of 11 to 15 seconds using brain extract.

With a view to determining whether the acceleration of *the coagulation time found in association with haemolysis* was due to the liberation of haemoglobin into the plasma or to some other substance freed at the same time, the following series of experiments was designed.

A solution of "crystalline ox haemoglobin" was prepared containing 250 mg. in 2 c.cm. 0.9% sodium chloride (12.5 grammes haemoglobin per 100 c.cm.). This was added to plasma free from haemolysis in the proportion of 0.1 c.cm. of haemoglobin solution to 1 c.cm. plasma. We have unfortunately been unable to trace the source of the preparation of haemoglobin used. It was contaminated with methaemoglobin. To an equal amount of the same plasma was added 0.1 c.cm. of freshly withdrawn human blood (14 grammes of haemoglobin per 100 c.cm.) completely haemolysed by saponin. The coagulation times of the specimens of plasma so treated were then determined with venom and brain extract (Table II). It is evident from Table II that the acceleration of the coagulation time produced by the addition of blood haemolysed by saponin exceeds that produced by the addition of haemoglobin, which is slight and may not be significant. This result suggests that the factor responsible for the acceleration may not be haemoglobin. Leathes and Mellanby

(1939) had already reported to the Physiological Society the potentiating effect of lecithin on the thrombokinase of daboia venom, and we accordingly determined to try the effect of lecithin. Lecithin was added to the venom as already described: we have also added it to the plasma in the proportion of 0.1 c.cm. ovolecithin to 1 c.cm. plasma.

The results of the third series of experiments are given in Table III, which shows that the acceleration of the coagulation time produced by lecithin is of the same order as that produced by "slight" haemolysis. Under the conditions of the experiment the addition of lecithin to the

venom was more efficient than its addition to the plasma. The adjuvant effect of lecithin, like that of haemolysis (Table I), is more apparent when venom is the source of thromboplastin. Again little significance attaches to the differences observed with brain extract.

The effect of haemolysis and of lecithin in accelerating the coagulation time as determined by Quick's method on plasma, in which the prothrombin content is reduced, is shown in Table IV, which gives the results obtained in nine

cases of jaundice. Both "marked" haemolysis and the addition of lecithin shorten the coagulation time when either venom or brain extract is the source of thromboplastin. The effect is greater with haemolysis. Even the shortened coagulation times are, however, still grossly in excess of those obtained with apparently normal blood (Table I).

The results of our investigations have been summarized in the accompanying distribution diagram. This shows the wide range of variation obtained when venom is used as the source of thromboplastin. The distribution curve is bimodal, with peaks at 15 and 20 seconds. Diluted venom tends to give times rather longer than those with the more concentrated preparation. When lecithin is added to the venom the coagulation times are shorter and the scatter appears to be reduced. In view, however, of the smaller number of observations it is impossible to be definite on this point. In the presence of haemolysis the coagulation time is further reduced and the distribution curve now shows a single peak at 9 to 10 seconds with a relatively small scatter. This appears to be the best curve of the series. The addition of venom and lecithin to

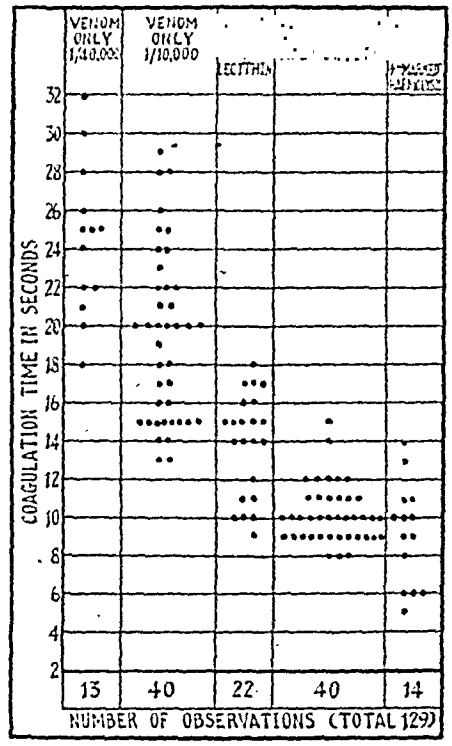

Diagram showing the variation in coagulation time obtained when venom is used as the source of thromboplastin.

haemolysed plasma produces coagulation times which tend to be shorter still, but the data are not sufficient to warrant a definite statement.

Conclusions

The results here set forth would appear to indicate that Russell-viper venom alone is unsatisfactory as a source of thromboplastin. Its action can be potentiated by one or more of the products of haemolysis or by one or more of the constituents of ovolecithin, but it is not possible to say, as Witts and Hobson have done, that the adjuvant effect is due to lecithin. In nine cases of jaundice the effect produced by haemolysis was the greater. A preparation of haemoglobin was also found slightly effective. Acceleration of the coagulation time was greater with venom, but in the jaundiced cases occurred also with brain extract as the source of thromboplastin. In conditions of reduced plasma prothrombin the adjuvant effect of haemolysis and of lecithin can be demonstrated, but the reduced coagulation time still exceeds that of apparently normal blood. The influence of phospholipoids in the coagulation mechanism has been recognized for many years since Howell's original work on the subject, but the effect of haemolysis in accelerating the coagulation time has not been reported hitherto. It is this aspect which we particularly wish to stress. Plasma free from haemolysis contains phospholipins, and the presence of haemolysis adds to their amount to an immeasurably small extent. It would appear, therefore, that some highly active substance is liberated from the red cells. Our results suggest that this may be a phospholipoid. On more mature reflection we wish to retract the last statement in our letter (Crosbie and Scarborough, 1941): we have not been able to decide whether there is any advantage in determining this reduced coagulation time when investigating the presence of low plasma prothrombin. Our results support the valuable suggestion made by Witts and Hobson

that a new technique is available for the study of haemorrhagic diseases in the determination of coagulation time (Quick) with Russell-viper venom before and after the potentiating effect of ovolecithin, but we feel that work of a more specific nature is required before ascribing this effect to lecithin. Special precautions will, however, be necessary to avoid even a trace of haemolysis.

Summary

The effect of haemolysis in accelerating the coagulation time of plasma is recorded.

Experiments dealing with the influence on the coagulation time of the addition of venom and lecithin to haemolysed plasma are described.

The conclusions derived from the investigation are given

Acknowledgment is made to the Moray Fund of Edinburgh University for a grant towards the expenses of this investigation.

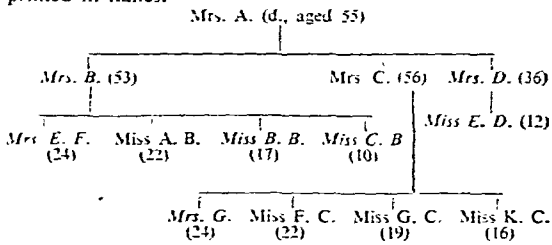
CYCLICAL MUCOSAL ULCERATION

BY

M. H. PAPPWORTH, M.D., M.R.C.P.

Medical Officer to the Surrey County Council



Recurrent buccal and genital ulceration is a syndrome which has attracted but scant attention. Recurring ulceration of the mouth is a common condition, described in textbooks under varying titles—ulcerative stomatitis, dyspeptic ulcers, aphthous ulcers, periadenitis mucosa necrotica recurrens (Sutton and Sutton, 1935), and stomatitis neurotica chronica (Sibley, 1899 and 1914). Recurring ulceration of the vulva was first described by Lipschütz (1913). He called the condition "ulcus vulvae acutum," by which name it is usually known, and in a second paper, in 1923, he reported 51 cases, but only 1 of these also had buccal ulceration.

The coexistence in the same patient of both conditions—namely, non-venereal ulcerative lesions of the mouth and genitalia—was originally described by Neumann (1895). and Wien and Perlstein (1932) in a comprehensive review of the subject could find reports of such a combination in only 30 cases and themselves described a single case. Since then Ravell (1932), Gray (1932), Thompson (1932), Talalov (1934), Hunt (1934), Ziserman (1935), Deuell and Landon (1936), Behcet (1937), Michaëlis (1937), and Tagami (1937) have reported between them 19 cases. In only 9 of the total of 50 cases is there any mention of the effect of menstruation on the ulcers, and in only 6 of these had the ulcers a regular time relation to the menstrual cycle—three cases of McDonagh (1924) and those of Talalov (1934), Ziserman (1935), and Michaëlis (1937). In 5 of the 8 cases recorded below the ulcers bore a constant time relation to menstruation, and it is this association of the ulcers with menstruation that I particularly wish to emphasize.

In all the patients whom I have seen with this condition the stomal and the genital ulcers have always had the same general characteristics. They vary in size from a pin-head to about one centimetre in diameter, and their appearance is preceded by and associated with pain at the site of ulceration, often malaise and depression, and occasionally dyspeptic symptoms. They are superficial, often appearing to start as small papules or vesicles; they are surrounded by an inflammatory halo, their bases covered with a yellow slough, and they heal without scars. I have seen them on the inside of the cheeks, lips, tongue, tonsillar region, and pharynx, and also the labia, vagina, and cervix uteri. The number of ulcers present at one time varies from one to about twelve. They are unassociated with an adenitis.

Of the 8 cases reported below the most interesting is a group of 6 patients, all of whom are near relatives. Mrs. A. died, aged 55, from cancer of the uterus. There is no history that she or her only sister had complained of either buccal or vulvar ulceration. But Mrs. A. had three daughters—Mrs. B., Mrs. C., and Mrs. D.—of whom the first and the last both suffer from recurrent ulceration, as do also three of Mrs. B.'s four daughters, one of Mrs. C.'s four daughters, and the only daughter of Mrs. D. All the male members are healthy.

The following diagram illustrates the position more clearly. Ages are given in brackets and the initials of those who have buccal and/or genital ulceration are printed in italics.

Case Records

Case 1.—Mrs. B., aged 53, has had buccal and vaginal ulcers for twenty years. The stomal ulcers occur on the inner aspect of the lower lip and at the side of the tongue. There is usually only one mouth ulcer present at a time. The vaginal ulcers always occur at the same time as the buccal and are accompanied by a great deal of soreness. All the ulcers appeared two to three days before the onset of menstruation and disappeared during actual menstruation, but they always reappeared for two or three days after the period had ceased. Her menstrual cycle was always regular 3/28 until the menopause, but the flow was scanty and she had severe premenstrual and intramenstrual dysmenorrhoea. Since the menopause the ulcers have still regularly recurred every four weeks. During her four pregnancies the ulceration was always very much worse, but it improved following delivery. The only investigation has been a blood Wassermann, and this was negative. She has had no treatment whatsoever for the condition. Mrs. B. has four daughters, and three of these have ulcers. The eldest, Mrs. E. F., has genital and mouth ulcers, but further details about her are not available.

Case 2.—Miss B. B., aged 17, the third daughter of Mrs. B., has had mouth ulcers for eighteen months but no genital ulcers. The ulcers have occurred regularly every four weeks, and last for one or two days. Although she is nearly 18 she has never yet menstruated, and secondary sexual characteristics have not appeared. Her general nutrition is poor and she is pale. Apart from these facts there are no other positive findings, and no investigations have been undertaken. She has not had any special treatment.

Case 3.—Miss C. B., aged 10, the fourth daughter of Mrs. B., has been troubled with ulcers on the side of her tongue at irregular intervals for the last eighteen months. Recently they have been very large and painful, previously having been only small and causing little inconvenience. She is a well-built, healthy-looking child, and there is no evidence of infection of her teeth, tonsils, or sinuses. No investigations or special treatment have been undertaken.

Case 4.—Mrs. D., sister of Case 1, is aged 36, and has had ulceration of the mouth and vulva since the age of 12—two

years before the onset of menstruation. The buccal and genital ulcers occur simultaneously two or three days before the onset of menstruation. They invariably disappear as soon as menstruation starts, but reappear for the two or three days following the cessation of the period. The menstrual cycle is regular 3/28, and there is no dysmenorrhoea. She is an exceptionally healthy-looking woman, and apart from the ulcers there are no positive physical signs. She has never had any treatment for the condition, and no investigations have been done. She has one son and one daughter, the latter also suffering from ulcers. During the two pregnancies the ulcers were very much worse.

Case 5.—Miss E. D., aged 12, the daughter of Case 4, has had ulceration of her tongue and cheeks frequently, but at irregular intervals, during the last twelve months. She has not yet started to menstruate and appears to be a healthy child, no abnormalities having been observed on clinical examination.

Case 6.—Mrs. G., aged 24, niece of Cases 1 and 4, has had recurrent buccal ulceration since childhood. The ulcers occur at irregular intervals and last one or two days. They have no relation to her menstrual cycle, which is regular. There is no history of genital ulceration. She has two daughters and one son, all of whom are healthy and free from ulcers. Her mother and three sisters are also not affected. She is the only daughter of Mrs. C. who bears a strong resemblance both in appearance and in temperament to Mrs. B. (Case 1).

Case 7.—Mrs. J. was 21 when I first saw her. She then had an acute bronchitis, and remarked casually that an ulcer in her mouth was a little troublesome. On questioning I discovered that she had had ulcers of the mouth regularly every month, one week before the onset of menstruation, for two and a half years. The ulcers lasted until the period began. There is no history of genital ulceration. The menstrual cycle is regular 3/28, and there is no dysmenorrhoea. Apart from bronchitic signs nothing abnormal was discovered on clinical examination. She refused further investigation. For the last two years I have been in frequent communication with her. During this period she has been entirely free from ulcers, although she has had no treatment.

Case 8.—Miss L., aged 45, was first seen by me when she had typical angioneurotic oedema of her face and arms. On routine examination ulcers were found in the mouth. Questioning elicited the fact that she had suffered from these for over three years. They always began one week before menstruation and lasted until the period started. There is no history of genital ulceration. Until twelve months ago her menstrual cycle was regular 5/28. Her general condition is good and, apart from the ulcers and recurring angioneurotic oedema, which bear no time relation to one another, clinical examination was negative. A blood Wassermann was negative and a blood count showed 4,232,000 red cells and 7,600 leucocytes per c.mm. with a normal differential count and 85% of haemoglobin.

One c.cm. of antuitrin S was given daily for one week before the expected onset of the ulcers. After the second course no ulcers occurred that month for the first time for over two years, and the following month she had only one small ulcer. The next month the ulcers were as bad as ever and, in view of the fact that the injections appeared to cause severe constitutional upset, 100 units of pregnyl and 20,000 units of oestroform were substituted. During the following three months she had only two small ulcers and the associated pain was much less; but she developed a severe epimenorrhagia, and so the pregnyl was discontinued and the oestroform given alone. The following period was normal, but the ulcers were very severe. The next month, after a further course of oestroform, she had amenorrhoea and was free from ulcers. Since then she has had 100 units of pregnyl on each of the seven days preceding the expected onset of the ulcers, with varying success. Although the condition has somewhat improved it cannot be regarded as cured.

Aetiology

In discussing the various opinions as to the aetiology the main difficulty is to attempt to elucidate whether or not the authors were describing the same condition as is reviewed in this paper. The exact relation of this syndrome of cyclical mucosal ulceration to similar conditions reported by other writers is hard to assess.

Lipschütz (1923) regarded *Bacillus crassus* as the causal organism of ulcus vulvae acutum and considered the finding of this bacillus as essential for the diagnosis. *B. crassus* is closely related morphologically to, if not identical with, Döderlein's vaginal bacillus. Several authors believe that recurrent buccal and genital ulceration occurring in the same patient is also due to *B. crassus*. But this organism is often in vaginal swabs of patients who have no ulceration: repeated attempts at auto-inoculation have all proved negative, and in only 4 cases has *B. crassus* been found in mouth ulcers.

Talalov (1934) described a patient in whom ulceration of the mouth and vulva was associated with a pustular eruption of the face and trunk which later ulcerated in parts. *B. crassus* was seen in a section taken through one of these ulcers and was isolated from the vulva but not the mouth. That author expressed the opinion that the patient had a generalized *B. crassus* infection, and quoted the case of Samek and Fischer (1929) of a girl of 19 who had ulceration of the vulva and a lesion of the legs resembling erythema nodosum. *B. crassus* was recovered from the genital ulcers, the skin nodes, and a blood culture.

Planner and Remenovsky (1922), Schnabl (1927), Samek and Fischer (1929), Kumer (1930), Jaffe (1930), Matras (1932), Whitwell (1934), Talalov (1934), and Hunt (1934) have each recorded a single case of recurrent ulceration of the mouth and/or of the vulva in association with skin lesions which either resemble erythema nodosum or are papular and may ulcerate. The skin lesions have been regarded by some as tuberculides, but others consider the whole condition to be a type of erythema multiforme. Talalov suggested that the skin eruption is an allergic manifestation of a *B. crassus* infection.

Cantrell (1934) and Grant (1934) have each reported a case of combined vaginal and buccal ulceration due to the diphtheria bacillus, but it is highly improbable that any of the cases above recorded were due to this organism. Kumer (1932) considered, on experimental grounds, that recurrent stomal ulceration is an atypical herpes infection, but this view has had very little support and no confirmation.

An endocrinous theory of origin appears more entertaining than an infective one, but is even more difficult to prove. Ziserman considered that because his case cleared up with anterior pituitary lobe extracts and stimulating *x*-ray doses to the pituitary he had established the endocrinous nature of the condition. Four of my cases appear to support an endocrine basis strongly, but the evidence is far from conclusive. Perhaps it is of some importance to note that amenorrhoea, physiological or otherwise, was associated with amelioration of symptoms in some cases and with aggravation in others. The syndrome of recidivating buccal and genital ulceration seems to be peculiar to women. If this really be so, what is the significance?

McDonagh (1924) reported a case in which the ulcers of the vulva occurred immediately after the cessation of the menstrual period, and he mentioned that he had seen two similar cases. *B. crassus* was found in all three, and McDonagh stated: "Menstruation does lower a woman's resistance, and doubtless in these three cases it sufficed to render a saprophytic organism pathogenic." Opposed to such a viewpoint is the fact that in 4 of my cases the ulcers started before the onset of the period, the possible exhausting effects of which cannot therefore be considered a contributory factor.

Parkes Weber (1932), in a discussion on the subject, suggested that the primary factor was not a local infection but rather some condition of the mucous membranes analogous to epidermolysis *bullosa*, which is not necessarily hereditary. The familial incidence of the condition in 6 of my cases favours such an interesting idea.

In view of the occurrence of mucosal ulceration in agranulocytosis the possibility of such a condition in these patients has to be remembered. No investigated case has had a neutropenia. Embleton (1937) described the interesting case of a girl who had ulceration of the mouth regularly every seventeen to nineteen days, the attacks always being coincident with a marked neutropenia, the leucocyte count being normal between the paroxysms. Embleton states: "There is no relationship between the swing of the rhythm and the menstrual periods." But unless the menstrual cycle was extremely irregular it is difficult to understand how this could have been the case.

I suspect that cyclical mucosal ulceration, at any rate as a partial syndrome, is far commoner than is generally believed. Possibly many girls who have genital ulceration do not seek medical advice because of false modesty, especially if they are single. In cases of stomal ulceration the relation to menstruation may not be volunteered by the patient even if present or be asked about by the doctor, who is probably unaware of such an association. Almost all previously published cases have been severe, but some of mine were mild and lead me to suppose that frequently the condition does not trouble the patients enough to make them consult a doctor, and Case 7 of my series indicates that spontaneous cure does apparently occur.

I wish to emphasize that none of the 8 cases described above has ever been an in-patient of any hospital.

Summary

Eight cases of cyclical mucosal ulceration are described, six of the patients being near relatives. The ulceration affected the mouth in all cases, and in two the genital tract was also involved.

My thanks are due to Dr. E. Pearson, without whose help this paper would probably never have been written.

SOME RECENT AIR-RAID CASUALTIES

BY

MARGARET BALL, M.R.C.P.

AND

GEORGE QUIST, F.R.C.S.

Registrars at the Royal Free Hospital

The treatment of air-raid casualties at this hospital during the past few weeks is here recorded because a few points have arisen which may be of value in the conduct of further cases.

First Series of Cases

Twenty-three casualties were brought to hospital; the injuries were due mostly to the direct action of the explosive, the distribution of the fragments being such that nearly all the lesions were in the lower limbs. Of the 23 patients 6 were dead or died within a few minutes of admission. Of the remainder, 8 died within twelve hours and 9 survived. These 17 patients were admitted to the receiving ward within thirty minutes of the time of injury, and resuscitative treatment was started immediately. They were all between the ages of 19 and 30; their lesions were lacerations or compound fractures of one or both lower limbs, with shock and local injury roughly in proportion. It was found that they could be put into one of two groups with reference to severity of the shock and treatment (and, one might add, prognosis also, as was unfortunately confirmed by the poor results of resuscitative treatment). One group, containing 9 cases, were all suffering from severe shock and had comminuted compound fractures of one or both lower limbs. The other group, consisting of 8 cases, only slightly shocked, had multiple lacerations, some also with compound fracture of one limb.

The former group were from the start too ill to allow of immediate operation; they were all in the clinically recognizable state of severe shock and had to be resuscitated before operation could be considered. They were given morphine and blood or plasma transfusions. In not one case was there bleeding from a large artery. The results of resuscitation treatment were extremely disappointing. Of these 9 patients 8 progressively became worse, and they died in ½, 3¼, 4, 6½, 6½, 6½, 8, and 11 hours. The other patient improved sufficiently for operation to be performed after six hours, and after much anxiety he survived. The second group never really gave rise to any doubt about their treatment and immediate prognosis. All 8 were operated on within six hours, mostly by excision and plaster, and have done extremely well.

It is not proposed to describe the general organization or the routine treatment, which was on generally accepted lines, as frequently described in recent articles (Cohen and Schulenburg, 1940; Hodgson and McKee, 1940). The operative technique was that described by Cohen and Schulenburg in their excellent paper, except that in their cases "no attempt at excision or trimming of muscle was made," whereas in our cases excision of damaged muscle was regarded as an important step in the procedure. A few cases only will be detailed, as they were of uniform type in the two groups. Of the 9 patients with severe shock the following case was typical:

A man aged 22. Compound comminuted fracture of upper end of left tibia and fibula with much destruction of tissue and the limb almost completely severed; a tourniquet had been applied just above the knee. This patient was suffer-

THE METABOLISM, EXCRETION, AND HUMAN REQUIREMENTS OF CALCIUM

BY

R. A. McCANCE, M.D., F.R.C.P.

(*From the Department of Medicine, University of Cambridge*)

Until the Government decided to fortify bread with calcium in the interests of national health the metabolism of this element had been the concern only of specialists in the subject. These international investigators, many of them with years of research and clinical experience behind them, had established certain facts as beyond all question, and it was no doubt on the weight of their findings that the Government based its proposal. As so often happens in this country of free and independent thought and speech, the Government's scheme was immediately criticized in various ways, counter-measures were put forward, and for the last six months or more the whole matter has been hotly debated in the lay and medical press.

In matters of this kind only people who are familiar with the facts can form any sound judgment. Those who are not tend to be swayed by the party which is able, or takes the trouble, to make the most noise. It may be of value, therefore, to outline briefly some of the generally accepted facts about calcium metabolism, and in their light to discuss an article which has recently appeared in this *Journal* (Harris, Ireland, and James, 1941).

Storage of Calcium

Calcium is an element which is essential for life and health and which at the same time is not at all easily absorbed. There are several reasons for the latter. One is the valency of the element, divalent cations being absorbed much less readily than monovalent. Another is the tendency of the element to form salts which are insoluble in the intestinal juices. Nevertheless, the requirements of bones and teeth demand that children shall store calcium at the rate of about 2 grammes per week from the time they are born till they are 17 or 18 (Leitch, 1937). Absorption and storage are facilitated by vitamin D, but no amount of vitamin enables a child (or an adult) to dispense with calcium itself. If children are to store 2 grammes per week they should be supplied with *at least* three times this amount, because much of the calcium in the food always escapes absorption and some of the calcium which is absorbed is inevitably excreted in the urine or finds its way back into the intestine as a constituent of the digestive juices. Adults require less calcium than children because their bones and teeth are fully formed, but their needs for maintenance are just as important. If sufficient calcium is not supplied to adults their bones tend to become rarefied and therefore liable to fracture (Owen, Irving, and Lyall, 1940).

Most of this knowledge of human calcium requirements has been gained by experiments in which the intake of calcium in the food has been balanced against the output in the urine and faeces. These experiments are not easy to carry out, and considerable experience is required to make them a success, but many satisfactory ones have now been performed, and from them it is easy to see in any particular instance whether the calcium in the food has been sufficient to promote satisfactory storage or maintenance. The papers of Bauer, Albright, and Aub (1929) and of Hunscher *et al.* (1934) contain excellent examples of such work, and for a summary, review, and application of such investigations Leitch's (1937) article should be consulted. The last word has naturally not been said, but certain facts are clear. One is that the amount of calcium retained by a normal adult over any given period of time is never more than a small percentage of the intake. Another is that normal men and women excrete 10 to 50% of their intake of calcium in the urine, 50 to 90% in the faeces.

If more calcium is absorbed than the body requires the excess is excreted in the urine. The amount so excreted is always small, and variations in it make no appreciable difference to the total osmotic work of the kidney, most of which is devoted to the excretion of urea, sodium, potassium, chlorides, and phosphates. Thus Borsook and Winegarden (1931), who set out to calculate in great detail the osmotic work performed by the kidney in producing one litre of urine, came to the conclusion that the total work amounted to 704 gramme calories and that the quota of this due to the calcium ion was only 1 gramme calorie—i.e., about 0.14%. Previous estimates of the total work of the kidney in producing a litre of urine had been of the same order (Cushny, 1926), and the principles and methods of all these authors were accepted as being substantially correct by Eggleton, Pappenheimer, and Winton (1940).

Optimum Calcium Requirement

On January 11 a paper by Harris, Ireland, and James appeared in this *Journal* entitled "Optimum Calcium Requirement." To the public and to most of the medical profession this article probably bears the stamp of having been written by experts and as such commands respect. Indeed, the views of the authors have already been given wide publicity, and it is because of this that I have ventured to write this cautionary note. To those who have made a careful study of physiology and calcium metabolism there are many features of this article to which serious exception must be taken. The section of the article headed "Calcium Balances" illustrates this. The authors give a series of balances in adults and discuss them as an integral part of the paper. A table shows the averaged intakes and excretions at different levels of intake. In every case the urinary exceeds the faecal calcium, sometimes by two to three times! Furthermore, some of the retentions of calcium amount to over 70% of the intakes. It is most unlikely that all previous investigators have been wrong on these two points and that Harris *et al.* alone are right. Yet the latter make no reference to any previous work. Surely some of it was known to them. There is no doubt that experienced investigators, finding themselves in disagreement with all previous workers, would not have published their findings without a full description of their methods and the steps they had taken to satisfy themselves that their results were the correct ones. Harris *et al.* have furnished us with none of this information.

Later in the article Harris *et al.* take up the question of the work of the kidney at various calcium intakes. They quote without reference (but with a spelling mistake) a formula for determining the work of the kidney and give some results of their own. They claim that lowering the calcium intake reduced one person's kidney work from 18.8 to 5.1 litre atmospheres/litre and another's from 14 to 0.9 litre atmospheres/litre: 14 litre atmospheres is the work equivalent of 339 gramme calories. If this figure is compared with those of Borsook, to which reference has just been made, it will be seen that it is too small to be a reasonable estimate of the total work of the kidney, and 0.9 litre atmospheres (21.8 gramme calories) is ridiculously small. One is forced to conclude that there is something radically wrong with Harris's figures. Furthermore, when it is recalled that, according to experienced authors (Borsook and Winegarden, 1931), the work done by the kidney on the calcium ion forms only 0.14% of the

total work, it is impossible to see how any physiological or pathological change in the excretion of calcium could possibly produce a significant rise or fall in the total work of the kidney.

Positive Calcium Balances

One further point. Under the heading "Positive Calcium Balances" Harris *et al.* allude to experiments on rabbits in which the animals were given diets rich in calcium, and their aortae subsequently analysed for this element. In a short table figures are given for *two* experimental animals and *one* control. The former's aortae contained 16.2 and 16.9 mg. calcium 100 grammes and the latter's 9.0 mg./100 grammes. These findings are claimed to be of significance to those interested in the aetiology of clinical arteriosclerosis, and they are employed to emphasize the dangers of high calcium diets in man. Now rabbits are animals which are well known to vary considerably among themselves. They are much less uniform than the inbred laboratory rat, and large numbers have to be used to establish differences of this kind. Yet Harris *et al.* do not give the number of animals used or their diets. They say nothing about the times for which the diets were administered, nor do they even mention the range of variations in the normal or in the experimental animals. Moreover, even if these experiments were repeated and confirmed it would not follow that the same would happen in man. Apart from the differences normally found between species, the rabbit's aorta is peculiarly liable to atheromatous degeneration when the diet is rich in cholesterol, and it may have an equally unusual calcium metabolism. So far as man is concerned there is no evidence that a high calcium diet leads to a deposition of calcium in healthy tissues. If there are degenerating areas in the body calcium phosphate may be deposited therein, whether the intake is high or low.

The results described in the article under criticism will carry no weight with the professional scientists until they have been repeated and confirmed by independent authorities. It is very much to be hoped that the public and the medical profession will take the same view.

It is the object of the Cicely Northcote Trust, attached to St. Thomas's Hospital, to experiment in new forms of social service and to extend the social work of the lady almoner's department from the out-patients and casualty cases to the ward patients and their families. The thirty-first annual report contains no statistics or audited accounts for the very good reason that many of the records, case papers, and books were lost in the destruction which befell parts of St. Thomas's Hospital by enemy action. The workers, however, were unharmed and the work has gone on. Throughout the year, in spite of calamity and disorganization, it has been possible to continue the systematic care of all the patients suffering from cancer. The plight of these patients during the early part of the war, when chronic wards were in many cases emptied and homes for cases of advanced disease ceased to admit, was often a desperate one. Some of these people have now been evacuated to the country, but it is stated that while a number are delighted by the peaceful surroundings, there are others who look upon the experience as one to be endured rather than enjoyed, and some who refuse to leave the part of London they know and, in addition to the sufferings entailed by their malady, face outside danger and discomfort with quite extraordinary courage.

Clinical Memoranda

Carbuncle of the Duodenum

The following case has three points of interest: (1) the difficulty in pre-operative diagnosis; (2) the unusual finding in "acute abdomen"; and (3) the satisfactory response to heroic treatment in an aged patient.

CASE REPORT

A woman aged 84 was admitted to hospital on December 5, 1940, complaining of continuous acute abdominal pain of five days' duration. The pain was generalized in the abdomen, but was most severe in the right upper quadrant. There was no complaint of nausea or vomiting. The previous history was negative for serious or relevant illness.

On admission the examination showed the patient to be well preserved for her age. There was no evidence of jaundice. The temperature was 98° F., the pulse 88, and the respiratory rate 22. Nothing abnormal was detected in the various systems beyond a degree of arteriosclerosis and a systolic murmur at the apex. The abdomen showed limited respiratory excursion and a girdle of pigmented moles at the waist-line. On palpation there was generalized tenderness, most intense in the right hypochondrium. A freely movable rounded mass about the size of a hen's egg could be felt immediately to the right of and slightly above the umbilicus. Liver dullness was normal, and localized dullness was elicited over the tumour. The remaining areas of the abdomen were uniformly tympanitic. On auscultation bowel movements could be heard. A tentative diagnosis of acute cholecystitis was made, and the patient received expectant treatment during observation.

On December 6, there being no improvement, laparotomy was performed by Mr. Richard Warren, through a right paramedian incision, under gas-oxygen-ether anaesthesia. On opening the peritoneum a mass covered by omental tags was seen in the right upper quadrant. The gall-bladder was identified and exonerated. The fundus of the stomach was traced down into the omental-covered mass, which was only slightly adherent and was easily stripped off. The lesion was then seen—a carbuncle, oval in shape, two inches by one inch, situated on the anterior surface of the first part of the duodenum. There was no macroscopic perforation into the peritoneal cavity, but six necrotic "pointing" areas were noted under the membrane. On palpation it was thought that an ulcer crater the size of a sixpence could be felt centrally in the carbuncle within the lumen of the bowel. The lesion was oversewn with a continuous catgut suture, and posterior gastro-jejunostomy performed.

Unfortunately, bacteriological investigation was inopportune, but 1 gramme of prontosil soluble was given empirically, twice daily for five days by the intramuscular route. Recovery was uneventful and the patient was discharged well on December 30.

Our thanks are due to Mr. Richard Warren, honorary surgeon to the hospital, for permission to record this case.

KENNETH MACCOLL, M.B., Ch.B.,
House-physician.
CYRIL A. ANDERSON, L.R.C.P. & S.I.,
General Hospital, Weston-super-Mare. House-surgeon.

Note on the Treatment of Acute Bacillary Dysentery with Sulphapyridine

The treatment of acute bacillary dysentery with sulphapyridine (M & B 693) has proved with us to be highly efficient. We have treated 20 patients (dysentery Shiga, 4; Flexner-Y, 13; Strong, 1; Sonne-E, 1; Schmitz, 1) with results so uniformly good even in the severe cases that we feel justified in publishing our observations in spite of the relatively small number of cases. It should be pointed out, however, that the drug seems to have no effect whatsoever in amoebic dysentery.

All our patients were adults suffering from severe or moderately severe bacillary dysentery. Mild cases have not been

treated, and cases without subsequent bacteriological confirmation, though treated, have not been taken into consideration. The treatment was started on the second day after admission to hospital, the first day being used for observation in order to compare the patient's condition before and after the administration of the drug. One gramme (two tablets) of sulphapyridine was given by mouth (together with sodium bicarbonate in order to avoid nausea) three to four times daily for two to four days, according to the time taken in recovery. As a rule the drug was administered until one day after the motions became formed. No other treatment was given.

Usually twenty-four hours after beginning the treatment the fever dropped and the diarrhoea was greatly improved as to the frequency of motions and the appearance of the stools. After forty-eight hours' treatment the motions were back to normal in nearly all cases, irrespective of the duration of the disease previous to treatment and the type of the dysentery bacillus. In three instances it took three days and in one case four days to achieve this result. Tenesmus and vague sensations of uneasiness in the abdomen were felt for one or two days more by some patients. General toxic symptoms, though not very severe, observed in one Flexner and two Shiga cases, also improved very rapidly. The stools were found bacteriologically negative as soon as they became formed, and relapses have not been observed. It might be hoped, therefore, that chronic colitis which develops so often as a sequela even after mild cases of bacillary dysentery will be prevented by this treatment.

The accompanying table summarizes our results. The number of motions a day is used as the symptom best indicative of the patient's condition. The first day of hospitalization (observation day) serves for comparison with the ensuing days of treatment.

Table showing Results of Sulphapyridine Treatment of Bacillary Dysentery

Case No.	Type of Dysentery	Day of Disease when Admitted	Motions per Day						Duration of Sulphapyridine Administration (Days)
			Observation Day	Day of Treatment					
				1st	2nd	3rd	4th	5th	
1	Flexner-Y	3	26	8	2	1	1	1	2
2	Flexner-Y	3	23	8	1	1	1	1	2
3	Shiga	6	29	13	8	3	2	1	4
4	Flexner-Y	2	46	52	10	3	3	1	4
5	Flexner-Y	2	34	38	19	0	1	1	3
6	Flexner-Y	2	19	30	4	2	1	1	3
7	Shiga	6	56	13	0	0	1	1	2
8	Flexner-Y	4	8	10	0	1	1	1	2
9	Sonne-E	6	15	11	4	1	1	1	2
10	Flexner-Y	9	14	4	3	2	1	1	3
11	Flexner-Y	3	18	16	0	1	1	1	2
12	Strong	1	9	12	2	1	1	1	3

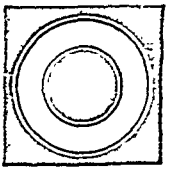
We wish to express our thanks to Col. G. W. Heron, Director of Medical Services, Palestine Government, and to Dr. G. Stuart, Deputy Director (Laboratories), for permission to publish this article.

RUDOLPH REITLER, M.D.
KURT MARBERG, M.D.
Government Isolation Hospital and Government Laboratory, Haifa.

P. Pribat (*Thèse de Paris*, 1940, No. 168) states that of the complications caused by beauty cures and cosmetic preparations the most serious are those due to hair dyes and decolouring agents. The largest number of cases of dermatitis are caused by tinctures containing aniline derivatives. The dermatitis is due to individual intolerance and in every respect resembles the complications of chemotherapy. Prophylaxis consists in the application of a skin test made from twenty-four to forty-eight hours before the use of the tincture. The complications belong to the group of allergic affections whose pathogenesis is still obscure.

Reviews

ORTHOPAEDIC OPERATIONS



Orthopedic Operations: Indications: Technique and End Results. By Arthur Steindler, M.D., F.A.C.S. (Pp. 766; 322 illustrations. 50s.) London: Baillière, Tindall and Cox.

This book is a mine of information based on the experience of one who has spent a surgical lifetime in the practice and teaching of orthopaedics. The material is well organized and illustrated and there are many references. The author does not confine himself to description of orthopaedic procedures, but devotes some space to indications, results, etc. Considering the great number of operations on the locomotor system that have been described it is not possible to include them all in one volume. However, as the author points out in the preface, many operative procedures have been omitted because their validity did not impress itself sufficiently or they represented merely irrelevant variations of a general principle.

The subject-matter is presented as follows: The book is divided into three sections. The first deals with general principles pertaining to orthopaedic operations from all points of view—biological, anatomical, pathological, and clinical. It is brief and therefore in some respects incomplete. Some of the subject-matter would have been better left to more general textbooks—for example, the diagnosis and treatment of acute dilatation of the stomach. There is a short, well-illustrated section on regional anaesthesia. The last chapter in the first section is a description of the surgical approach to the various regions of the body, and includes sufficient references to the surgical anatomy to make the method of approach clear. The second section, "The Technique of Orthopedic Operations," is divided into several parts depending on the type of tissue—tendons, fascia, ligaments, bones and joints, nerves, skin, etc. Each one of these chapters contains an adequate description of all the well-known orthopaedic procedures relating to the particular type of tissue. The book itself is well worth reading, and this particular section is of great value to the orthopaedic surgeon. The third section is concerned chiefly with the indications for operations and end results in specific orthopaedic conditions. These specific conditions completely cover the field of orthopaedic surgery. This section is not for the beginner. Many controversial subjects are raised, and the author expresses opinions sometimes in a dogmatic manner that would be actively contested by many orthopaedic surgeons. The breadth of the subject covered in this section enforces brevity which sometimes leads to statements that might be misleading—for example, in the discussion of scoliosis it is stated that in the congenital type it may be advisable to fuse a primary lumbar and a secondary dorsal curve. This follows a reference to the Risser methods of correction. It would be unfair to suggest that misleading statements are frequent: they only occur in the more controversial subjects, and chapters discussing such subjects as congenital deformities and spastic paraplegia are masterpieces of clarity and completeness and reflect the author's wide experience.

The rather unusual manner in which the subject-matter is assembled may make it necessary to refer to several chapters to get all the desired information. This is facilitated by a complete index of authors, operations, and conditions. Criticisms of this volume are prompted by the dictates of perfection. Every surgeon doing orthopaedic work will find it of inestimable value.

A NEW NOTE is sounded in the management of NORMAL PREGNANCIES . . .

by Fall's advice, that progestin be used prophylactically to guard against abortion in expectant mothers who must make long journeys, who suffer severe mental shock occasioned by the receipt of bad news, etc., or who are the victim of febrile disease, in which the hyperpyrexia might induce an obstetrical accident. RADIOGRAPHY OF HEART DISEASE

Atlas of Cardio-Roentgenology. By Hugo Roesler, M.D., F.A.C.P. (Pp. 124; 166 illustrations. $8.50 post paid, or £2 7s.) Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox. 1940.

Prof. Roesler's monograph contains not only an excellent series of *x*-ray photographs illustrating the common forms of heart disease, but also many photographs of hardened specimens by which the anatomical and *x*-ray changes may be correlated. The *x*-ray silhouette of the heart and great vessels is, of course, flat or two-dimensional, but by further comparison of the actual organs a truer conception of the *x*-ray appearances in terms of volume, or three dimensions, is possible. Throughout the subject is treated by the presentation of actual cases, including the history and clinical findings, *x*-ray appearances and electrocardiogram, and photographs and descriptions of the corresponding specimens, which are shown sectioned in several planes. In some instances *x*-ray pictures of the specimens after injection with opaque material are also reproduced. First the radiological and anatomical appearances of the normal heart are studied at different age periods and with different positions of the diaphragm, then the various causes of cardiac enlargement and displacement. A striking illustration is given of the changes in heart volume, pulse rate, and electrocardiogram which occur in postural circulatory deficiency. Coronary artery disease is visualized directly by the *x*-ray demonstration of calcification in the arteries, and the various results of cardiac infarction are well shown. Calcification in valves and pericardium, which is not easy to record radiographically and probably often missed, is clearly demonstrated. Other common lesions of heart, vessels, oesophagus, and mediastinum are adequately represented. The book is extremely well produced and its study will be found a pleasure.

WAR SURGERY

Surgery of Modern Warfare. Part I. Edited by Hamilton Bailey, F.R.C.S. Section I: Wounds: General Considerations. Section II: Special Considerations. (Pp. 160. 12s. 6d. net, plus 6d. postage.) Edinburgh: E. and S. Livingstone. 1940.

This book is the first part of a symposium on war surgery under the editorship of Mr. Hamilton Bailey, and the later parts will be published from time to time. The names of no fewer than sixty-five contributors appear at the beginning of the work, and this accounts for some of the editor's difficulties in controlling his team. With such a galaxy of talent it is almost inevitable that there should be some lack of balance in the various chapters, certain inconsistencies, and in places too much enthusiasm on the part of individual contributors. The present volume is devoted to a consideration of the general and special features of war wounds and their treatment. It includes accounts of projectiles, the classification of wounds, the treatment of shock, the uses of transfusion and infusion, and chapters dealing with the various types of wound infection and their treatment. Some of the important sections suffer by being over-compressed. This is particularly true of the chapter dealing with burns, which is excellent but not nearly detailed enough for a work of this sort. The chapter on transfusion and infusion is, on the other hand, extremely complete. One of the greatest difficulties that the editor and his contributors have had to face is the fact that at the present time surgical ideas of wound therapy are in an unusually fluid state. For this the experiences of the Spanish war with the closed-plaster treatment and the introduction of chemotherapy are largely responsible. The chapter on chemotherapy is by Dr. W. R. Thrower, who is described as consulting physician to Messrs. May and Baker Ltd. The introductory paragraph of this seems to ignore some of the earlier work on modern bacterial chemotherapy. The contributor further suggests that the use of sulphonamides locally appears "quite irrational." Yet, in a later section dealing with gas gangrene, another contributor specifically advocates the direct application of sulphonamide powder for these anaerobic infections. In the matter of dosage this latter contributor suggests that 15 *grains* is the maximum dose recommended. This should be 15 *grammes*. There is no account of serum therapy in the treatment of gas gangrene, though experimental evidence supports its use, but a full account of the use of *x* rays is given. One contributor condemns the fluoroscopic removal of foreign bodies, while a later one advocates this and describes the method in detail.

This book is very readable, well produced, and well illustrated. In attempting such a work Mr. Hamilton Bailey has called to his assistance too much talent rather than too little, and he has the added difficulty of the present rapidly changing scene in the sphere of wound therapy. It is to be hoped that in the later parts of the work the lack of balance between the various sections, the inconsistencies, and the tendency to over-simplification of some of the sections will be corrected or overcome.

VULVAR DISEASES

Diseases Affecting the Vulva. By Elizabeth Hunt, B.A., M.D., Ch.B. (Pp. 215; with 36 illustrations, and 18 plates in colour. 21s. net.) London: Henry Kimpton. 1940.

Dr. Elizabeth Hunt's book on diseases affecting the vulva is a valuable addition to the practitioner's library. It is the product of many years' study, and is both scientific and practical. The most interesting and novel view put forward in this volume is that lichen planus attacks the vulva far more commonly than is generally supposed and that it is one of the common causes of pruritus, and, moreover, that one form of it is identical with the leucoplakic vulvitis described by Bonney which later develops into the atrophic condition known as "kraurosis." Here she differs from another authority, Dr. Agnes Savill, who is of opinion that kraurosis is a terminal stage of an infective recurring dermatitis. There is undoubtedly very considerable difficulty in unravelling the relationships of the various chronic eruptions and changes that affect this region, and not very much help is to be gained from the histological evidence afforded by biopsy. Careful following up of the clinical histories of the patients is essential, and as pruritus is usually a leading sympton the sufferers are very prone to wander about from hospital to hospital or doctor to doctor, and thus baffle the investigator. Dr. Hunt has devoted a large proportion of her book to the study of this question, and of eighteen coloured illustrations no fewer than eleven are devoted to some form of lichen planus. In some cases we rather fancy that other dermatologists would not agree with the diagnosis, but undoubtedly serious consideration must be given to Dr. Hunt's main proposition, which is that lichen planus is far more often responsible for vulvar disease than has previously been supposed. Among the questions which arise from the discussion of this point is the very important one of the relation between the different forms of lichen planus and the incidence of malignant disease. In other parts malignancy and lichen planus do not seem to run together. In the vulvar region epithelioma not infrequently supervenes on leucoplakic vulvitis. This is a point which needs explanation.

One practical warning is given by Dr. Hunt to practitioners when she points out that the vulva is for the most

part an area of skin rather than of mucous membrane; hence inflammatory changes here need treating as a dermatitis; and hence the poor results obtained from the administration of alkaline hip-baths, too often prescribed in cases of pruritus. Finally, we must add a word of praise for the coloured illustrations made by the Dufay process. The besetting sin in this method of colour photography is that it is liable to exaggerate the reds, but in these plates this fault has been largely avoided. The book is exceedingly well got up. We recommend it to dermatologists, and perhaps even more warmly to gynaecologists.

Notes on Books

A cheap edition of Mr. SIDNEY FORSDIKE'S *Textbook of Gynaecology* has been published by William Heinemann (Medical Books), Ltd., at 7s. 6d. If the advances in knowledge of the last five years are forgotten while this useful little edition is read the reader will be impressed by its amazing value. It is concisely written, lavishly illustrated, and filled with sound clinical teaching and accurate observations. Since the original text was written, however, hormone activity has been more thoroughly investigated and endocrine therapy has developed on a rational basis, the sulphonamide drugs have proved their worth, endometritis has been recognized as a pathological entity not to be confused with stages of normal endometrial proliferation, and valuable work has resulted in a better understanding of the pathology of ovarian tumours. In view of these and other developments it is to be regretted that no attempt has been made to bring this little edition up to date. None the less the book is a bargain for the reader prepared to make the necessary marginal corrections.

The Cambridge University Press has published, in the standard form, Abstracts of Dissertations Approved for the Ph.D., M.Sc., and M.Litt. Degrees in the University of Cambridge during the Academical Year 1939–40. The summaries are arranged in the alphabetical order of the faculties. There are five biochemical dissertations, two on experimental psychology, and one on a physiological subject.

Preparations and Appliances

TECHNIQUE FOR FASTENING A CASUALTY ON AN A.R.P. STRETCHER WITH TRIANGULAR BANDAGES

Mr. H. F. HODGES, staff officer for stretcher parties, and Dr. E. B. GROGONO, medical officer for civil defence (Woodford Green), write:

By the method described below a patient can be kept on his or her side in reasonable comfort without interfering with respiration; the stretcher can be tipped, deliberately or accidentally, to any angle, and even inverted, without risk to the patient. The method may be used for lowering certain cases, either from an improvised crane or by sliding the stretcher down a ladder; and to provide additional safety and comfort for certain cases in ambulances.

The injuries for which it might be employed include complicated fracture of ribs, shattered jaw, concussion, etc. It is possible to argue that almost every unconscious patient with risks of respiratory obstruction from tongue and vomit should be placed and secured in this position for an ambulance journey, in which the attendant has very poor facilities for performing her alleged functions.

The actual bandages are so well illustrated by the diagrams of Miss E. M. Watts, our ambulance officer, that only minor comments are needed. (*a*) The two interlocking bandages on the uppermost shoulder keep the patient fixed on his side and, although fastened quite firmly, do not interfere with respiration. We have, on a stretcher, been turned to every conceivable angle, and this bandage prevented movement, took much of our weight in various positions, and was surprisingly comfortable. The fold of the blanket, i (Figs. 1 and 5), comes

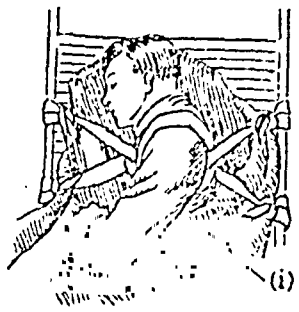

FIG. 1

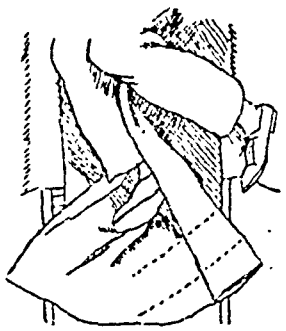

FIG. 2

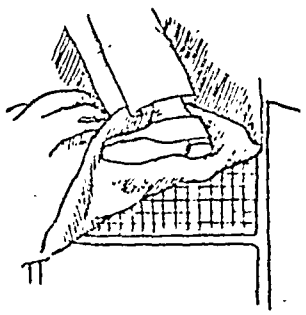

FIG. 3

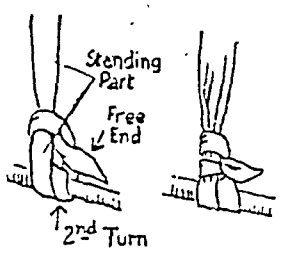

FIG. 4

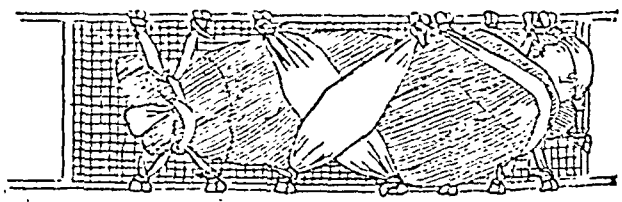

FIG. 5

up over these bandages easily to wrap the shoulder. (*b*) Careful padding between the ankles is important (Figs. 2 and 3). (*c*) The knots used are simple but extremely important. The reef, as such, is useless and dangerous. A round turn on the stretcher bar should be secured by two half-hitches of the free end about the standing part. "Two round turns and two half-hitches" (Fig. 4) are better still—even if the knot is thus brought fairly near the end of the bandage—as it also takes most of the strain off the knot itself. It is immaterial whether the two half-hitches are tied the same way—making a clove-hitch as in the diagram—or in opposite directions.

DIPHENAN B.D.H.

Diphenan B.D.H. is a preparation of *p*-benzylphenyl carbamate. This is a non-toxic anthelmintic which has established a considerable popularity under a proprietary name.

Great difficulties attend alterations in nomenclature of drugs, and Messrs. B.D.H. issued a leaflet in January, 1940, explaining their policy in cases such as this: We are glad to note that they accept the principle that "official or recognized names" should be used when these are available. We suggest, however, that their leaflet requires revision, since in the list of substances for which there is no such official or recognized name available the first two examples are anacardone and iodatol. Anacardone is nikethamide (*B.P.*, 1932, 3rd Addendum) and iodatol is stated to conform with the specification for iodized oil (*B.P.*, 1932, 1st Add.). In this matter of nomenclature the interests of the medical profession are perfectly clear. The practising doctor cannot be expected to know more than one name for a drug, and knowledge of a single name ought to be sufficient to permit him to identify a drug even when several different brands are on the market.

CALCIUM REQUIREMENTS

Calcium is an essential constituent of the diet, and the need for it continues throughout life. This is most imperative in the period of growth and adolescence, in pregnancy and lactation, but is none the less imperative in adult life and old age. Many factors are concerned with the metabolism of the element, and knowledge of some of them is still very incomplete.[1] Vitamin D plays an important part in its absorption from the gut and deposition in the bone, and it is well to remember that calcium cannot be retained in the absence of adequate phosphate. Certain of its salts, such as oxalate, are insoluble in the intestinal juices, while the phytic acid of cereals may immobilize further quantities. Recent experiments on man and animals[2] show, however, that calcium as carbonate, gluconate, or phosphate is almost as available as the calcium of milk. Lactose and citric acid favour its absorption. Even at best calcium is probably utilized by adults and children only to the extent of some 20–30%, though the efficiency may be much higher in young infants (Mitchell[1]). On the other hand, it seems probable that at certain stages of growth, at least, children have no maintenance requirement and deposit all the calcium they manage to absorb.[3] Absorption and retention of calcium by both man and animals is definitely influenced by the degree of calcium saturation of the organism, and this may greatly affect the outcome of balance experiments. Of the ingested calcium, some passes through the gut unchanged, some is absorbed and may be retained, and some is excreted in the urine. Relatively large quantities are poured into the intestinal tract with the digestive juices, and these may be partly reabsorbed, but the remainder may serve to swell the faecal excretion. Man excretes the bulk of the calcium in the faeces. It is only exceptionally, on very low intakes or under abnormal conditions, that urinary losses predominate. As a rule the calcium content of the diet has but little effect on the blood calcium level, but the rabbit is a notable exception, and it is generally acknowledged that this animal is unsuitable for most investigations on calcium metabolism.

In recent years much work has been done on the calcium requirements of man, and several estimates have been put forward. Probably the best known is that of Sherman,[4] who sets the lowest maintenance requirement of a 70-kg. adult (male or female) at 0.45 gramme of calcium a day. This is a bare minimum, like the lowest figures for protein requirements of Chittenden and Hindhede. It is customary to add to it a margin of safety of 50%. In this country the careful work of Owen[5] gave a slightly higher maintenance value, 0.52 gramme—almost the same as that calculated by Leitch[6] from an impressive array of data. The requirements of children and of pregnant and lactating women are higher than those of adult males and unencumbered females. Thus the League of Nations' estimate[7] allows a child 1 gramme daily and the expectant or nursing mother 1.5 grammes. Lactation imposes a very heavy drain of calcium, and some workers believe that it is not possible for a freely lactating woman to remain in positive calcium balance and that she must draw on her reserves (Mitchell[1]). Figures used for the assessment of requirements of populations are therefore higher than those for adults. For the population of the United States, little differing from ours in age and sex distribution, Stiebeling[8] used the value of 0.6 gramme, or, with the 50% margin of safety, 0.9 gramme. For the whole population of England and Wales Crawford and Broadley[9] have calculated from the B.M.A. minimum diets a figure of 0.7 gramme (or 1 gramme if the more generous standard of the League of Nations is used); and Leitch's[6] estimate is 0.76 gramme.

How do results of our dietary surveys compare with these estimates? The best-known is that of Sir John Orr.[10] It shows that the poorest 10% of the population, half of whom are children under 14, get only 0.37 gramme calcium daily; a further 20%, or nine million people, again including many children, only 0.52 gramme; and the next 20% only just touch the bare minimum of 0.61 gramme. These disturbing findings are amply confirmed in other surveys—for example, the comprehensive one of Crawford and Broadley[9] or that of Potts,[11] who reported that the average daily consumption of calcium in sixty-three families in Yorkshire with four to six children was only 0.37–0.43 gramme a head. There is, in general, a marked correlation between the intake of milk and of calcium, and reports from various distressed areas show how appallingly low is the consumption of milk by the poor population.[12] Gaunt and his co-workers[13] fed to rats an exact replica of a poor human dietary (the Peterhead diet), and showed that the performance of the animals was subnormal but that it could be greatly improved by the addition of calcium and phosphorus. Here the experiments of Sherman and his pupils[14] are of interest. They studied the effects of increasing the calcium content of a diet which had supported "normal" nutrition through forty-three generations of rats. An increase from the original 0.2

to 0.35% of calcium by the addition to the diet of calcium carbonate was followed by a more efficient utilization of the food, better growth, earlier maturity, several indications of higher adult vitality, a longer period between the attainment of maturity and the average length of adult life. Further increases to 0.64 and 0.8% produced a higher level of nutritional well-being throughout life, and the authors concluded that "the level of calcium intake most conducive to optimal well-being is significantly higher than that required for normal growth and maintenance." Whether the same is true of man is not known, but excellent health and performance have certainly been observed on calcium intakes very much higher than those of the population of the British mainland. In the Island of Lewis, where the maternal "efficiency" is high and teeth are excellent, the daily calcium intake is 1.12 grammes per head.[15] The virile population of Finland takes 25% of its caloric intake as milk and milk products,[16] and its calcium supply must be of the same order as in the Island of Lewis. The athletes competing in the last Olympic games at Berlin took, according to Berg,[17] from 2.0 to 3.5 grammes of calcium daily.

It appears reasonably certain that the calcium intake of the population of this island as a whole is inadequate, and unless some measures are taken the position will deteriorate further owing to war conditions. Cheese is now, and is likely to be, in short supply. There was a temporary shortage of liquid milk last winter, and, though the dairy cow has been given precedence over all other stock in matters of rationing, it is impossible to predict how much foodstuff will be available and to forecast the position next winter. Similarly, imports of dry and condensed milk may be curtailed by other demands on shipping, though every effort should be made to bring to this country and sell cheaply the largest possible quantities of this most important protective food. The increasing home production of green vegetables should help to improve the calcium supply, but greens get short towards the end of winter. The force of circumstance lends support to the Government's decision to fortify bread with calcium. This measure is nutritionally sound, should help to increase the supply for those who need it most, and has much to commend it as an emergency step in wartime, provided it is not misused as a political placebo. There should be no need for such an expedient in peacetime, and we are entitled to hope that post-war reconstruction will put an end to the evil of malnutrition and bring a healthy and complete diet within the reach of all. The idea of adding calcium salts to the diet is not new, and has been carried out with good results in India by Aykroyd,[18] and has also been sponsored recently by Mitchell.[1] The amount and the nature of the calcium salt to be added to bread are still not settled. The decision rests presumably on the outcome of experiments at present in progress, and the results will certainly be awaited with interest.

The situation regarding calcium requirements and metabolism, as summed up here, is sharply at variance with views put forward in an article which appeared recently in this *Journal*.[19] Dr. R. A. McCance and Miss Isabella Leitch, both eminent students of mineral metabolism, explain in our present issue (pp. 276, 291) why the evidence presented in that paper is likely to carry but little weight. Their evidence is also supported by Dr. J. Douglas Robertson (p. 292). No more need be said here than that it was fitting that a statement of experimental results and an opinion on them, however unorthodox, should have been given the freedom of publication, and that it was no less fitting that this should be put in its proper scientific perspective. Seen thus, against the background of accumulated experience, the utterance of Harris and his colleagues is not likely to affect or alter our present views on the calcium requirements of man or on the deficiency of this element in the present British diet.

CHEMOPROPHYLAXIS OF GAS GANGRENE

We suggested only three weeks ago[20] that the experimental method had gone far enough in studying the treatment of gas gangrene, and that the need of the moment is for data obtained in the clinical field. Of treatment this remains true, but the results described by Dr. Frank Hawking in our present issue (p. 263) show that something of importance remained to be discovered about how to prevent infection of this kind. They are not the first, but perhaps they are the most striking illustration hitherto of what may be achieved by the timely local application of sulphonamide compounds. This is a form of chemotherapy—it should rather be termed chemoprophylaxis—which has been almost entirely neglected until recent times, for reasons which are not far to seek. Until it became known how these compounds act on bacteria there was little reason for supposing that they would have a local action; indeed, Continental authorities maintained views about their mode of action with which the idea of any local and direct effect on bacteria was incompatible. Domagk himself, and other German writers, have consistently denied that there is any direct effect on bacteria of a kind demonstrable *in vitro*; in their view the co-operation of the living body as a whole is necessary, and they seem almost to regard "true chemotherapy" as involving some mystery which can never finally be probed. Levaditi and other French workers have produced, among other ingenious red herrings, the idea that sulphanilamide is converted in the tissues into a different and more active compound, and described experiments in which introduction of the drug by some distant route was more effective than its injection directly into the peritoneal cavity, which was the site of infection. In the atmosphere created by repeated proclamations of this kind there was no encouragement to employ or even to think of sulphanilamide as a local antiseptic. Some enterprising clinicians had either escaped from or were unaware of this mephitic atmosphere, and applied sulphanilamide locally with good results before the work of Fildes and Woods[21] finally gave both systemic and local sulphonamide chemotherapy a completely rational basis. We now know that sulphonamide compounds act directly

[19] Harris, Ireland, and James. *British Medical Journal*, 1941, 1, 49.
[20] *British Medical Journal*, February 1, p. 166.
[21] *Brit. J. exp. Path.*, 1940, 21, 67, 74.

on bacteria by arresting a particular process in their metabolism; wherever these compounds exist in adequate concentration—what is adequate depending on available nutriment—the growth of susceptible bacteria must stop. Local application is therefore reasonable; whether it succeeds may depend on various local conditions and can best be decided by practical trial.

Hawking used the method devised by Legroux: muscles are exposed and crushed, the drug is then introduced in powder form, and a piece of material soaked in culture is placed in the wound, which is then sutured. In animals surviving three days the wound was reopened, the material removed, and more drug applied. In these experiments the large inoculum of bacteria so applied to damaged tissue produced an infection which was almost invariably fatal within twenty-four hours in untreated controls. Among the treated not only was life much prolonged but there were many survivors. In view of the enormous inoculum used, these results appear more striking than any previously obtained with systemic treatment, and a comparison of the two methods in these experiments decidedly favours local application, although it may be questioned whether intraperitoneal sulphathiazole gives the systemic its best chance. It is interesting that this experiment reverses the routes employed by Levaditi and Vaisman[22] in an experiment already quoted, and leads to exactly the opposite conclusion. The details of these results demand careful study, complicated as they are by the use of three drugs and three species of bacteria. Against infection by *Cl. welchii* sulphathiazole is the most effective, with sulphanilamide running it close; a mixture of the two was tried in a smaller number of animals and may perhaps be better than either. Sulphapyridine, on the other hand, is decidedly inferior to either. The order of merit is the same against *Cl. oedematiens*, but *Cl. septique*, although well controlled by sulphathiazole, is almost entirely uninfluenced by sulphanilamide. These differences are due only in part to degrees of specific activity: a study of the fate of each drug in the tissues showed, as would be expected from their differing solubility, that sulphanilamide attained a high concentration but disappeared rapidly; sulphapyridine persisted for ten days, but never attained a concentration of 50 mg. per 100 c.cm. at all; whereas sulphathiazole, having evidently an optimum degree of solubility for this purpose, persisted for four days in a concentration of over 100 mg. per 100 c.cm. Trials were also made of some other sulphonamide compounds, and of proflavine, which also proved capable of arresting the spread of infection. In future studies of this kind, whether experimental or clinical, acridine compounds still have a claim to consideration.

In interpreting these very favourable results it must be remembered that the drug was introduced before the bacteria. They are examples of pure prophylaxis; when treatment was delayed for two hours its efficacy was greatly reduced, and six hours' delay robbed it of all effect. By this time bacteria had doubtless invaded the muscle deeply and thus escaped from the area in which a high concentration of the drug is attained. It may be asked in view of this why local treatment with sulphanilamide has the effect with which it has recently been credited on wound infections which have existed for days or weeks. The probable answer is that in persistent suppuration most of the bacteria are in the fluid contents of the wound and only superficially situated in surrounding tissue, and therefore more accessible than in an acute and spreading infection. However these experiments may be interpreted, they place the chemoprophylaxis of gas gangrene on a footing which it previously lacked. To obtain clinical confirmation, as Hawking points out, will demand the comparison of this with other methods in a very large number of cases, and it may be long before results have accumulated on an adequate scale. To those not in a position to conduct such a study the sulphonamide pack may forthwith be commended as a promising method of immediate wound treatment.

INFLUENZA

As everyone knows, influenza is now abroad. For obvious reasons, epidemiological events have been awaited this winter with particular gravity. The enigmatic character of influenza accentuates the mood, because, whatever the logician may say, the coincidence of the last great war and the most deadly pandemic of influenza in recorded history affects the imagination, and, to our profession at least, the grimness rather than the gaiety of urban life has been impressive these past six months. It is too early yet to be sure that the present epidemic will not be an important cause of mortality, but not too soon to permit one to believe that a major epidemiological disaster is unlikely. In the first place, the age distribution of deaths ascribed to influenza has shown no tendency to pass from the normal type in which a large proportion of the victims are over 65 years of age, to the pandemic type in which those of younger age formed a larger proportion. A sudden change of age distribution was a dramatic feature of the great pandemic. In the next place, although the weekly totals of deaths in the 126 great towns were still increasing in the first week of February (the figures were, for four weeks ending with that mentioned, 99, 120, 176, and 261), and may be expected to increase further, the increase between the last two weeks is much less than in 1929—a bad year in which the first three weeks of the epidemic had figures almost identical with those of this year (99, 122, 179). The following figure was 321, and in that year the epidemic was well under way earlier in the season. Available figures of both hospital admissions and deaths in the London area suggest that the maximum of illness may already be behind us, and the maximum of deaths very near and much lower than that of 1929, even when allowance is made for evacuation.

No prudent man dogmatizes about influenza: it is not even true that when the spring flowers are in bloom all danger is over until autumn. Apart from the great pandemic, there have been severe epidemics in late spring and early summer, but none since 1918. In last year's epidemic deaths numbered 94 (in the great towns) in the first week of the year and 417 in the fourth week; there was then a decline to 353, followed by a sharp increase to 514; and the actual maximum, 629, was in the eighth week. In 1938–9 the first rise was a week earlier, from 89 in the week ending December 31, 1938, to 144 in the following week; as in the following year, there was decline and a secondary elevation—indeed two secondary elevations—but in the worst week there were only 285 deaths. We may go no further than to suggest that on the available evidence it seems unlikely that we shall suffer more this winter than last. Having regard to the

many good reasons for believing that opportunities for disseminating droplet infections are greater now than a year ago, this is a pleasant inference. It does not authorize the least relaxation of our endeavours to disperse the population.

THE SPINAL VEINS AND METASTASES

Recent work on the spinal veins suggests a possible explanation of certain modes of spread of malignant disease. By injection experiments Batson[1] has been able to show that there is a free passage by way of the spinal veins from the pelvic veins up to the cranium, and without recourse to the inferior vena cava. In human cadavers the dorsal vein of the penis was injected with diluted vermilion (Weber's artists' water colours), which could be easily seen, and which, from its crude sulphide of mercury, was also radio-opaque. The injection material spread through the prostatic venous plexus, the sacral and lumbar spinal veins. Thence, without entering the inferior vena cava, the injection material progressed in some experiments up the spinal canal to the base of the skull. Many intercostal veins were filled, as well as the veins of the bony pelvis. The experiments were repeated on living *Macacus rhesus* with colloidal thorium dioxide. *X*-ray examination showed that the injection material passed from the deep dorsal vein of the penis into the pelvis, and ascended the trunk by means of the inferior vena cava; but when the monkey's abdomen was compressed some of the thorotrast passed into the spinal veins and could be followed along them past the zone of compression into the thoracic spinal and lower intercostal veins. These experiments confirm the oft-repeated observation that spinal pressure is raised by abdominal compression. In coughing, straining, and other procedures that raise intra-abdominal pressure blood may be squeezed out of the abdominal veins into the spinal veins. It is well known that malignant tumours may spread by metastasis from the prostate and other pelvic and abdominal organs to the spine and cranium without any evidence, in the form of pulmonary metastases, that they have passed through the caval system and the lungs. Batson's observations provide an anatomical explanation of this phenomenon. In explanation of certain aberrant metastases from breast carcinoma Batson records that material injected into a breast vein of adult female cadavers may spread to the clavicle, intercostal veins, the head of the humerus, the cervical vertebrae, the transverse and superior longitudinal cranial venous sinuses, as well as to the azygos vein and the superior caval system. In some of these experiments the skin around the site of injection becomes flushed with vermilion, and the flush gradually extends past the middle line, even to the skin of the other breast. On the basis of this spread of injected material in the subpapillary venous plexus of the skin, Batson suggests that Handley's lymphatic permeation theory might be again studied with profit. It appears that there is a vast intercommunicating system of veins of which the spinal veins are the main channels. These veins for the most part lack effective valves, and are the site of frequent reversals of flow. They are thin-walled vessels and may be difficult to identify when empty of blood, but at operation may be of alarming size. They are a storage lake as well as a pathway of drainage. They provide a ready vehicle for neoplastic (and pyogenic) metastases. Batson suggests that these veins should be called the vertebral veins, and that they are of sufficient importance to be regarded, along with the caval, pulmonary, and portal systems, as one of the important venous systems of the body.

COMPARATIVE PSYCHOLOGY

We have been warned often enough that to argue from mice to men is full of fallacies, and nowhere more than in that domain where the superior organization of man is most definite—namely, the mental. Perhaps it is this caution that has deterred workers in this country from experiment in animal psychology. Whatever the reason, we have to go abroad, and especially to the U.S.A., for experimental studies in animal "psychology," which have flourished there under the stimulus of the pre-eminently American psychological system, Watson's behaviourism. Another approach to animal psychology, that of Pavlov, has been increasingly employed in a number of centres in the U.S.A. also, while it is doubtful whether a single laboratory has existed here for this purpose. Comparative psychology in this country has been practically confined to the observational method, employed, for example, on animals at a zoo. Let us hope that the war may give us as a people a greater interest in the uses of science as a means of social amelioration rather than of destruction; and that some of the increased wealth that Mr. Keynes paradoxically promises us after the war may be devoted even to such remote and apparently academic studies as experimental animal psychology.

These reflections are prompted by a contemplation of the *Journal of Comparative Psychology*, and of the copiousness of the output in this field in the U.S.A. Not that such studies always repay the labour spent on them. The experiment may amount to nothing more than a demonstration that what happens in humans has its parallel, or at any rate its analogue, in animals. For example, two papers on "regression" by L. I. O'Kelly[1] show that under the influence of pain an animal may revert to a mode of behaviour previously learned, although less effective for the task in hand than a method more newly acquired. This is consoling to those who have been a little disturbed by the readiness with which the concept of "regression" has been dragged in, among psychologists, to describe certain modes of behaviour which, while not "adult," were not such as ever had been seen on land or sea. But the fact that dissolution of habit does not always follow evolution probably depends partly on the complicated foundations of the structure of human habit. It is therefore comforting to find that a regressive piece of behaviour in the literal sense can be demonstrated experimentally. When all has been said, however, there is to the clinician an air of unreality about experimental work of this kind, perhaps because it is nearer the physiological than the psychological level. The affective side is absent, and the complicated business of social relationships, of which human behaviour in all but its simplest form is essentially a part, has usually to be left out. Nowhere does this strike the observer more forcibly than in Pavlovian experiments on the production of "neurosis" in dogs. But even here there is a satisfaction in demonstrating that pathological signs of behaviour can arise, not from lesions, but from a conflict of impulses in the cerebrum. The piece of work that has prompted these remarks suffers, alas! from other defects than this—defects primarily of simple failure of analysis. The fact that an animal which has learned two ways of getting at food drops one of these when it finds the method painful, and reverts to the previously learned one, seems not to be regression in the sense of regression as known in human psychopathology, but surprisingly sensible—not in the common sense, but in Starling's sense of the "wisdom of the body." The animal chooses not so much a regressive as a different path.

ZINC PEROXIDE FOR WAR WOUNDS

We drew attention last year[1] to the use of zinc peroxide as an application to certain types of infected wound. The originator and most persistent advocate of this treatment is Meleney, who first adopted it for a characteristic slowly spreading gangrene of the skin, of which he gave the first full clinical description. The infection in these cases, which usually develops in connexion with an operation wound of the chest or abdomen, is due to a microaerophilic streptococcus, and zinc peroxide is said to restrain the growth of this organism by continuously liberating oxygen. Later Meleney advocated the same treatment for infection by other streptococci and by anaerobic bacteria generally; indeed, the only common wound invaders said to be exempt from its action are staphylococci and coliform bacilli. Treatment with zinc peroxide is also strongly recommended by B. S. Freeman[2] for necrosing cancers and ulcers following irradiation of malignant growths. In many of his thirty-five cases the region involved was the mouth, and bacteriological study revealed mixed infections in which streptococci and anaerobic Gram-negative bacilli (*F. fusiformis* "*B. necrophorus*") predominated. Such bacteria disappeared in consequence of the treatment, anaerobes being the first to go; the clinical effects were rapid abolition of fetor and diminution of pain, contributing greatly to the patient's comfort. The technique of application is evidently important. Zinc peroxide powder is sterilized by dry heat and made into a thick paste with sterile distilled water; every crevice in the wound is then filled with this paste by a syringe or tube. Refilling is necessary several times a day for a lesion within the mouth, but an external wound can be dressed and left untouched for as long as two days; the dressings, which are additional to filling of the cavity with paste, are gauze soaked in the paste and several layers of gauze permeated with vaseline to prevent evaporation. The steps taken to ensure persistent contact between the antiseptic and every part of the infected surface probably have much to do with the success of this treatment. When other antiseptics are used it is often thought to be enough to apply a wet dressing which merely rests on the more superficial parts of the wound, leaving other parts untouched; whereas spraying, irrigation, or the method here advocated for zinc peroxide, can alone secure thorough and universal contact. A drawback to the use of zinc peroxide is the variable activity of different samples. The only make found by Meleney to be consistently active is not pure zinc peroxide, but a mixture of four different zinc salts, which suggests that oxygen liberation is not the whole explanation of its effect; the zinc ion itself may take part. If therapeutically active zinc peroxide is now available in this country, there may well be a field for its use in the treatment of some types of infection in war wounds.

INFERTILITY IN THE MALE

Considerable progress has been made during the last decade in the investigation of the infertile male. This divides itself naturally into two parts: the clinical examination and the semen analysis. Later, when the results of these two examinations are correlated, each will be found to throw light on the other—the medical history and the clinical examination explaining the semen findings, and the semen analysis suggesting the need for further investigation in order to discover the cause of any anomalies or deficiencies that may have been found to be present. A comparatively recent additional method of examination is by testicular biopsy. In 1913 Huhner advocated testicular aspiration as a diagnostic measure in cases of azoospermia. Although useful, aspiration of the testes provides far less reliable and complete knowledge than does biopsy, which has now completely superseded it. In the *Journal of the American Medical Association* of October 26, 1940, Dr. C. W. Charny gives an interesting paper on this subject. The technique of testicular biopsy is simple and can be performed in the consulting-room if measures for a strict aseptic technique are available. The whole operation can be carried out under local anaesthesia, although some pain may be felt on incising the tunica albuginea. This incision should be just enough to allow of a small bead of testicular tissue being extruded. This is cut off with curved iridectomy scissors, and submitted to microscopical examination. It is not generally necessary to suture the incision, but only the wound in the scrotal wall. Testicular biopsy gives direct evidence of the condition of the tubules. It allows, therefore, of differentiation between azoospermia due to blockage in the genital tract and to failure of spermatogenesis. What is equally valuable is the information that it provides concerning the results of treatment and for prognosis. When performed before and after treatment it yields the most direct evidence of the efficiency of the therapeutic agent employed. Since treatment has not made the progress that has been made in diagnosis, it is necessary to have some means of gauging the efficiency of the various therapeutic agents that are being tried.

In the same number of the journal appear articles on the diagnosis and treatment of male sterility and on the nature of human infertility, by A. R. Kreutzmann, S. R. Meaker, and S. N. Vose. The first-named author divides sterility in the male into two categories: urological and endocrinological. The disability may be either congenital or acquired. In the urological group the commonest cause of infertility is a blockage in the genital tract—usually in the epididymal canal—due to a previous attack of gonorrhoea. In the endocrine group the commonest cause is hypoplasia of the testes, due probably to a pituitary deficiency. Many of the latter cases prove difficult to explain, since outwardly the patients appear to be normal healthy men, and we have no laboratory tests by means of which we can diagnose minor degrees of pituitary dysfunction. Treatment of these cases is very difficult. Indeed, it must be confessed that the only satisfactory results obtained from endocrine therapy are those in which the infertility is due to hypothyroidism. Kreutzmann has obtained no satisfactory results from the use of testosterone propionate. Like other workers, he lays emphasis on the quality of the spermatozoa found in the semen rather than on their number. At one time it was believed that if the spermatozoon count was below sixty million per cubic centimetre of semen the man could, for all practical purposes, be considered sterile. It is now known that conception has followed from impregnation with semen with no more than three million per cubic centimetre. All investigators, however, confirm Moench's view that the number of abnormal spermatozoa should not exceed 25%.

We regret to announce the death of Emeritus Professor William Bulloch, M.D., F.R.S., consulting bacteriologist to the London Hospital.

The Red Cross and St. John Fund for the Sick and Wounded in the War now stands at £4,356,000.

CHARLES WHITE, AND THE GROWTH OF PROVINCIAL MEDICAL EDUCATION

PROF. BURGESS'S HUNTERIAN ORATION

The Hunterian Oration was delivered by Prof. A. H. BURGESS of Manchester before the Royal College of Surgeons of England, meeting at the house of the Royal Society of Medicine on February 13. Sir Hugh Lett presided.

Prof. Burgess mentioned that this was the eighty-first oration, and he was the first orator to be entirely a provincial surgeon—that is, one who had not received his medical education in London and who had not practised in London at any time. In the first part of his oration he spoke of his distinguished fellow citizen Charles White, F.R.S., who was born in 1728, the same year as John Hunter, whose fellow student and lifelong friend he was. White was also the founder of the Manchester Royal Infirmary and a pioneer in the prevention and treatment of puerperal fever. After thirty-eight years' service on the staff of the infirmary, White resigned owing to a disagreement with the board, and in the same year he founded the Manchester Lying-in Charity, the precursor of the present St. Mary's Hospitals for Women and Children, and for twenty-one years served on its staff under the singular title of "man-midwife extraordinary." In 1803 a severe attack of ophthalmia destroyed the sight of his left eye, but he continued to practise and even to operate until 1812, when a similar attack left him totally blind, and he died in 1813.

White's chief literary production was his treatise *On the Management of Pregnant and Lying-in Women*, first published in 1773, and dedicated to John Hunter, a treatise which embodied twenty-seven years of midwifery practice. His description of the lying-in conditions of those days, especially of how the unfortunate woman was almost hermetically sealed against any breath of fresh air, was a graphic piece of writing. One respect in which White was a pioneer was postural drainage. The credit for what was known as Fowler's position should really go to him. He also marvellously anticipated the essentials of sepsis and its prevention. He claimed indeed that of the large number of lying-in women whom he had attended he had not lost one from puerperal fever, though he qualified this statement later by making it referable to such cases as he had himself delivered throughout. A quarter of a century after White's death there was a serious fall from grace in the hygiene of childbirth, largely due to French teaching; the methods of White and his followers were abandoned and puerperal fever again became rife even in Manchester Lying-in Hospital, which White himself had founded.

A Pioneer in Prevention of Puerperal Fever

The claim so persistently made by Continental writers that the knowledge of the prevention and cure of puerperal fever originated with Semmelweiss in Vienna in the middle of the nineteenth century ignored the patient labours of White and of British obstetricians. Prof. Burgess showed how by successive stages spread over several years Semmelweiss arrived at the identical views and practice advocated by White eighty years earlier. The only point not specifically mentioned by White but stressed by Semmelweiss was the fatal part played by the examining finger stained with cadaveric material when students went straight from the dissection room to the lying-in case, but as Manchester at that time had no medical school the explanation of the omission was obvious. All honour to Semmelweiss for his courageous advocacy, in the face of strong opposition, of measures to diminish the appalling risks of childbirth, but they represented merely the reapplication of principles enunciated by White.

White was a most original general surgeon, and read many papers on surgical topics to the Royal Society. In 1762 he published a volume on the use of the sponge in stopping haemorrhage. He used dried sponge largely as a dressing, and seemed to have anticipated by over a century and a half the principle of the modern Winnett Orr treatment of acute osteomyelitis. Stone in the bladder was common in Yorkshire in White's time, and many cases were admitted to Manchester Royal Infirmary, where White soon acquired a reputation as a lithotomist. He was also a naturalist and was styled the father of anthropometry, which was true so far as the living subject was concerned. He was the first to discover that the forearm of the European was shorter as compared with the upper arm than the forearm of the negro, and that the negro forearm was shorter in comparison than that of the ape.

Beginnings of Provincial Medical Schools

The first course of medical lectures in the Provinces was delivered in 1783 at the house of the Manchester Literary and Philosophical Society by Charles White and his son Thomas, and four years later these two at their house in King Street started the first provincial classes, confined to medical students, with lectures in anatomy and physiology. Down to the early part of the nineteenth century anyone from the Provinces desiring to obtain a qualification was obliged to attend hospital practice in London before being allowed to sit for the licentiateship of the Society of Apothecaries or the membership of the Royal College of Surgeons. In 1814 Joseph Jordan, the father of provincial medical education, started a school of anatomy in Manchester, and in 1817 his lectures were recognized by the Society of Apothecaries, the first recognition of provincial medical instruction by any licensing authority in this country. In those days it was difficult to obtain bodies for dissection, and Jordan had to rely on "resurrectionists," which led to an infuriated mob assaulting his premises. A select committee on the subject was appointed by the House of Commons, and upon its report was founded the Anatomy Act of 1832, permitting the unclaimed bodies of persons dying in workhouses to be used for dissection. Jordan's school was closed in 1834, and its students transferred to a school founded by Thomas Turner, the first complete school of medicine to be established in the Provinces, later to be incorporated with Owen's College, the first constituent college of the newly created Victoria University. The power to confer medical and surgical degrees was not granted, however, until three years later, and then only in the face of the fiercest opposition from the Royal College of Surgeons and generally from the London medical schools.

Between 1824 and 1834 the medical schools of Manchester, Birmingham, Sheffield, Leeds, Bristol, Newcastle-upon-Tyne, and Liverpool were founded, also those of York and Hull, which were closed respectively in 1859 and 1870. The orator briefly sketched the famous controversy of one hundred years ago, in which Thomas Wakley of the *Lancet* took such a prominent part, in the fight for the recognition of the provincial medical schools. Looking back on that controversy, he said, one was left with the impression that the members of the Council of the Royal College of Surgeons at that period displayed an undue regard to self-interest and a narrowness of vision, happily quite foreign to the Council of these days, when the claims of the London and provincial schools were considered equitably and impartially and the representatives of each met in the utmost good fellowship. That the earliest provincial students were at any rate not in the rear of their London counterparts was suggested by some early pass-lists which Prof. Burgess showed.

Hunter and Lister

Although his oration was on the provincial surgeon, Prof. Burgess concluded with a tribute to the two greatest British surgeons, both of whom must be accounted metropolitan:

"John Hunter's indisputable right to fame immortal rests upon many factors, among them his unique knowledge of anatomy, both human and comparative, his persistent advocacy that structure is but the ultimate expression of function, his emphatic insistence upon the experimental method of investigation, and, as a crowning glory, the foundation of our superb Hunterian Museum, second to none elsewhere. No such mani-

WOUND-HEALING AND TISSUE-REPAIR

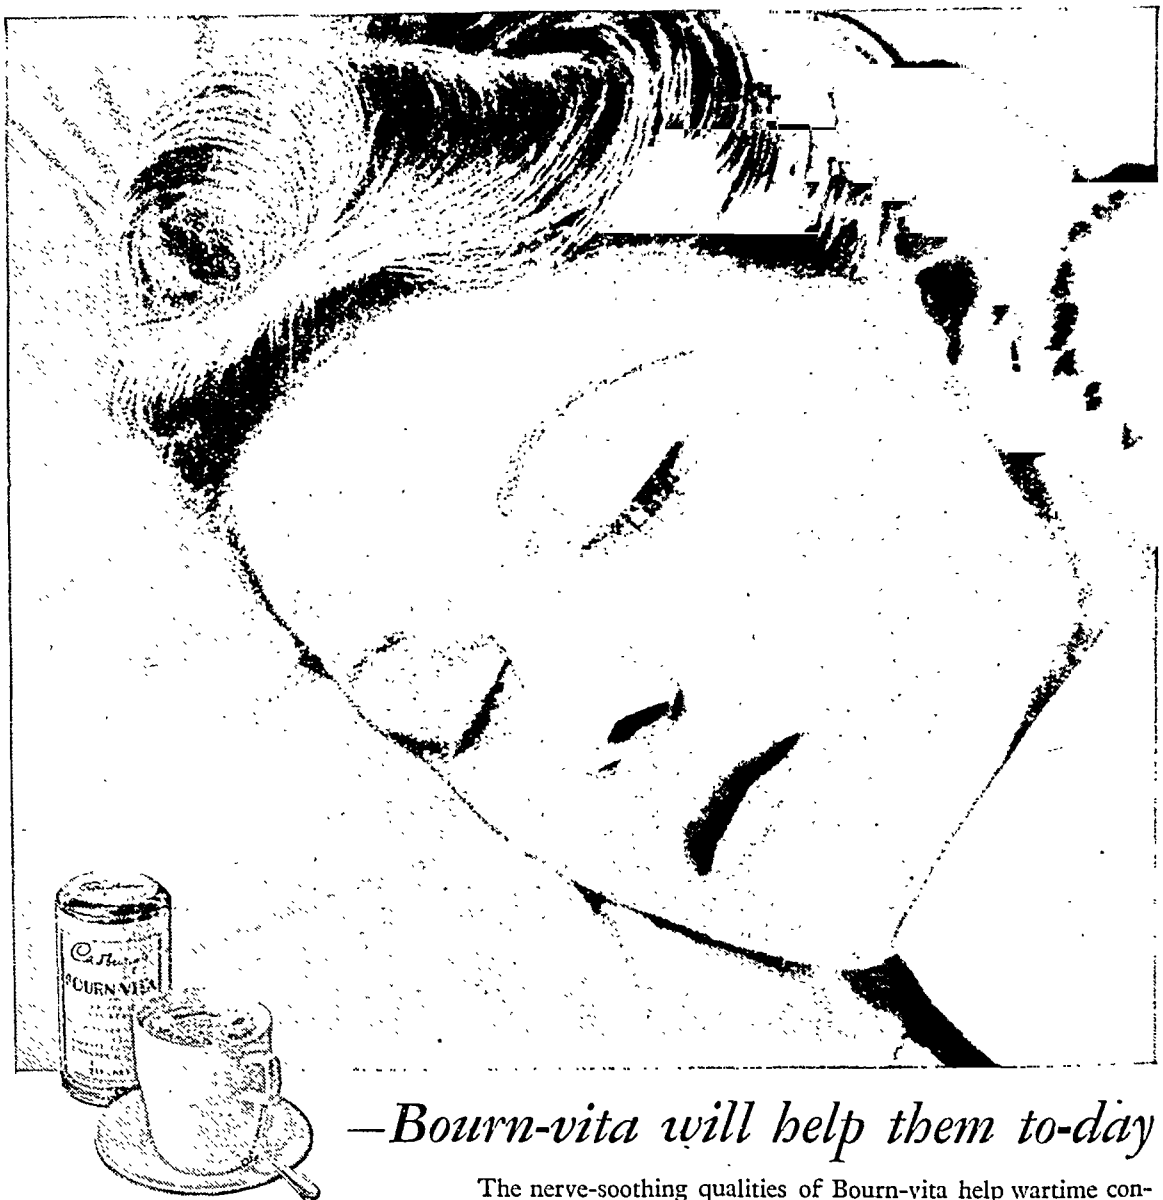
A New Therapeutic Agent

The healing virtues of Allantoin have been known for some years, but it is only recently that its unique property of cell-proliferation has been considered of potential value in modern therapy. Clinical research has shown that Allantoin is a powerful stimulant of epithelial growth, its local application causing rapid and healthy granulation in damaged tissue.

Moreover, it is significant that Allantoin, whether administered per os or parenterally, stimulates leucocytosis and increases the number of neutrophil cells.

Thus for the healing of chronic purulent wounds and, in fact, for all conditions where it is desirable to stimulate the growth of healthy tissue and combat infection, there is abundant evidence that Allantoin is likely to prove a most valuable chemotherapeutic agent.

Successful results have been recorded of its local application in the form of solution and ointment; internal lesions have also responded favourably following its administration.



The Research Laboratories of Genatosan Limited have devised a new method for the large scale production of Allantoin, and are now in a position to offer this substance in a high state of purity to the medical profession.

ALLANTOIN

GENATOSAN LIMITED, LOUGHBOROUGH, LEICS.

Convalescents must have sleep . . .

—Bourn-vita will help them to-day

The nerve-soothing qualities of Bourn-vita help wartime convalescents to get the most out of the sleep they need so much. The Vitamin B, phosphorus and calcium in Bourn-vita are all valuable nerve foods, and help to induce a restful, *natural* sleep. This nourishing food-drink, prepared by Cadburys, is especially light and digestible.

Cadburys BOURN-VITA

FOR DEEP, RESTORING SLEEP

fest memento of fame aids our remembrance of the other of Britain's two greatest surgeons. . . . Hunter founded a school, but Lister marks an epoch. Were the surgical era to be divided into two periods only, those in the minds of the great majority of surgeons would undoubtedly be pre- and post-Lister."

SHELTER PROGRESS

LONDON REGIONAL COMMISSIONER'S PROGRAMME

At the Tavistock Clinic on February 15 Alderman Charles Key, M.P., Regional Commissioner for London with special charge of the shelter problem, gave an address on that subject, taking the place of Miss Ellen Wilkinson, who had been announced to speak. Dr. Edward G. Glover was in the chair.

Alderman KEY said that the first problem which had to be dealt with was overcrowding. This had been tackled by the provision of new shelters. By the end of January the public shelters and the domestic shelters provided by the local authorities were sufficient to accommodate 80% of the population of the regional area, which was roughly coterminous with the metropolitan police area, or 92% of the (smaller) London County Council area; but, of course, they were not geographically distributed in such a way as to make them evenly available to the people. According to a census taken at the beginning of January, in the public shelters in the Council area, where there was provision for 19% of the people, only 4% were taking advantage of it, and in the domestic shelters, where there was provision for 74% of the people, only 14%.

Medical Arrangements

Eighteen local authorities in the London area had already appointed an additional medical officer of health for shelter work only. In four cases a resident shelter doctor had been appointed; in other cases whole-time doctors were appointed to be responsible for more than one shelter. On nightly visits to shelters 270 doctors were employed, and about the same number were on call. In practically all the 154 large shelters —that is, shelters accommodating 500 or over—medical aid posts had been installed, including sick bay, isolation bunks, and the necessary provisions. Of the eighty Tube stations seventy-four had been fitted with aid posts. Masks to the number of 200,000 to counter droplet infection were available, half of which had been distributed to the aid posts, the other half being held in reserve in case of an epidemic. An advisory committee of medical officers of health had been set up, and held regular meetings at which medical officers from different parts of the region attended and discussed their problems. Another small committee of medical officers and bacteriologists had been appointed to assist in dealing with shelter diseases; this committee had been fortunate enough to secure the co-operation of Dr. Gordon of Harvard University. A staff of about fifteen medical officers, transferred from their ordinary work at the Ministry of Health or other Government Department, were engaged in interviewing local medical officers and in seeing that the shelters were up to standard. Finally, he reported from the medical expert concerned that while a limited number of individuals using the shelters were known to be lousy, no evidence had yet been forthcoming to indicate any increase in the louse population.

With regard to welfare work, Alderman Key desired to see in each local government area in the metropolis, or outside of it if the shelter population in the large public shelters exceeded 10,000, a welfare officer appointed to organize and control the activities of the multitude of voluntary bodies which made their way into the shelters. While he did not want to discourage voluntary organization, there was a danger that some shelters were receiving "a surfeit of social solicitude," while others were starved in this respect. On the subject of feeding, he mentioned that Lord Woolton had agreed to give up his control of canteen arrangements and to pass it over to the Regional Commissioner. Bunks had been installed for 420,000 people, and were still being put in at the rate of 60,000 to 70,000 a week. Within a few days every one of the eighty Tube stations would have its complement. Closet accommodation had been provided in the proportion of about one to every twenty-five persons. Wherever possible the authorities were encouraged to change over to water-borne sanitation, but in the Tubes this was impossible. All the Tube stations being below sewer level, compressed-air ejection plants had been or would be installed. He was giving active encouragement to experiments in electrical heating, particularly convector heating, and he had induced the Treasury to sanction expenditure for that purpose.

Good General Health of Shelterers

Dr. R. P. GARROW, medical officer of health for Hornsey, who opened the discussion, said that in one Tube station in his borough the maximum capacity was 1,500 sleeping places, and in September it held 2,000 people nightly, but the regular night population was now only 600 or 700, so that the problem of overcrowding was settling itself. The predicted shelter diseases had been absent, and he had had only one case of a supposedly verminous person reported to him, and even that person turned out on investigation not to be verminous. A medical officer with oversight of four large shelters in the City of London said that the health of the people in the shelters was better than it would have been in their own homes. A fault of the medical aid posts was the absence of sleeping accommodation for the staff who were there all night. One speaker from Kensington said that at the five Tube stations in that borough cases of infectious disease had been discovered, but they had been removed, the premises disinfected, alternative shelter accommodation found for contacts, and there had been no spread. A Hampstead medical officer urged the appointment of more shelter marshals, who had a better opportunity of detecting physical or psychological disorders than the medical officer on a cursory inspection.

Alderman KEY said that people had an idea that Tube stations were the safest, yet the two greatest disasters so far had been at Tube stations. At certain of these stations a well-directed bomb might mean that the shelterers were drowned in London sewage. Safety lay not in concentration in large underground shelters but in dispersal in small ones. The Anderson shelter had proved surprisingly efficient. A disadvantage was the noise, but this would be minimized in a new pattern with a special reinforcement. With regard to welfare, he thought there was danger in too many entertainments and canteens, because the large shelters would be made over-attractive, and thus create a problem of public health. He was asked by a member of the audience where were the bad shelters, and declared that there were now no bad ones, though some were not good. The standard of shelter now provided was far better than was the case four or five months ago.

IN THE PROVINCES

Lord Horder, who has now toured Merseyside, Manchester, Liverpool, Bristol, Birmingham, and Coventry, has stated that the best shelter policy, judged by health and safety standards, is dispersal of the population, which can best be achieved by providing domestic shelters. The provision of such shelters, which is Birmingham's policy, is held up by shortage of labour.

G. Williot (*Thèse de Paris*, 1940, No. 342), who records eighteen cases in adults aged from 22 to 68, one of which is original, states that after a sudden or progressive onset ileo-ileal intussusception proceeds with more or less violent paroxysms until there is complete intestinal obstruction. Pain is the most important sign owing to its constancy and intensity. Its principal character is the occurrence of more or less frequent crises, which may be separated from one another by painless intervals ranging from several hours to several months. The attacks of pain are very often accompanied by digestive disturbance, such as vomiting, alternating diarrhoea and constipation, and melaena. Intestinal splashing, which is an important sign of obstruction of the small intestine, will be often found during an acute attack and is an indication for operation. The presence of an abdominal swelling in the hypogastrium or round the umbilicus is of great diagnostic assistance, but is unfortunately not constant.

Reports of Societies

CHEMOTHERAPY AND WOUND INFECTION

At the meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on February 11, a discussion took place on "Chemotherapy and Wound Infection." Sir WILLIAM WILLCOX, who presided, said that when nearly six years ago Domagk discovered dyes which inhibited or prevented the development of streptococcal septicaemia—a discovery followed by the work of Colebrook, Buttle, O'Meara, and many others—it was one of the greatest events in the history of medical chemistry, ranking with the discovery of salvarsan in 1909. These new drugs acted in collaboration with the body forces to control infection, having in reality—to use a word very much in vogue thirty years ago—an opsonic action. He urged the need for systematic observation of small groups of cases and for close collaboration with the laboratory.

New Antiseptics for Old

Colonel LEONARD COLEBROOK said that one aspect of wound pathology upon which stress was laid by Sir Almroth Wright in the last war was that every wound produced in the tissues was a honeycomb of dead spaces—spaces between muscle bundles and in the subcutaneous tissue—which inevitably became filled with serous fluid, an extremely good culture medium for certain pathogens, the commonest of which were staphylococci and streptococci. However carefully the surgeons sewed up and bandaged a wound it was often impossible completely to obliterate all dead spaces, and in such spaces there was opportunity for organisms to multiply until they overcame the leucocytes. Until recently there was no means of changing that congenial culture medium into an uncongenial one; the old antiseptics were mostly "quenched," to use Wright's term, and there was nothing which would remain for any considerable number of hours in the wound and be active in its bactericidal properties. But the coming of the sulphonamides had changed the picture. If haemolytic streptococci were planted in the dead spaces sulphanilamide would frequently kill them off completely, even without the co-operation of the leucocytes, which was not essential to the action of sulphanilamide. With staphylococci the position was less certain; it could only be ascertained by clinical control combined with bacteriological observation. By the early application of one of these compounds a large number of cases of gas gangrene, though probably not all, might be prevented. It might be hoped to prolong the safe period for surgical intervention—for complete surgical débridement. He referred in this connexion to the work of Tréfouël and Nitti of the Pasteur Institute, who had been quick to appreciate at the beginning of the war that owing to aerial bombardment there might be a great hold-up in the evacuation of wounded, and sought for some means of staying bacterial growth so that the surgeon could perform his operation later on. Experimenting with animals infected with *Cl. welchii*, they had been able to save a large number by local chemotherapy combined only with surgery to the extent of removing a foreign body whereby the infection was conveyed.

Local chemotherapy might also do much to remedy the present unsatisfactory position with regard to burns. A large number even of the less severe and extensive burns went septic sooner or later, and the sepsis increased the amount of tissue damage and delayed healing. The best hope of avoiding infection in burns was by using one of these compounds—he did not know at the moment whether it was best to employ it in the form of powder or in one of the pastes now being prepared. It might even be that ultimately sulphanilamide would not prove the best agent, but that some other substance like penicillin would take the field.

With regard to local chemotherapy of established infections, his colleagues Purdie and Fry were the first to report the application in streptococcal infections of the surface of the skin; but, unfortunately from the scientific point of view, the dramatic results obtained were spoilt by the fact that the drug was also given by the mouth in order to get the maximum therapeutic effect. Recently with Major A. E. Francis and with the co-operation of Sir Harold Gillies and his colleagues it had been possible to test out the value of this procedure in superficial wounds infected with the streptococcus, and it appeared that in the great majority of them much could be done by clearing up haemolytic streptococci within a very few days, but this work was only at its beginning. Colonel Colebrook ended with a word of caution. These treatments were likely to lend themselves to all kinds of abuse and misdirected effort. There would be a great spate of proprietary preparations, and it was important to make a critical approach, checking clinical impressions by measurements and bacteriological observations.

Benefit of Local Chemotherapy

Mr. EMLYN LEWIS spoke on the application of sulphanilamide powder to wounds and burns, saying, however, that, unfortunately for critical assessment, sulphapyridine had also been given by mouth in a number of the cases. Only sufficient powder was used to cover the wound, and after the application the wound was lightly packed with plain or vaseline gauze, or, where suitable, primary suture of the wound was performed, the powder being applied in the depths of the wound. No ill effects had been noted from this procedure, and as a rule it had not been found necessary to inspect the dressings until the fifth day, and even then it was very often only curiosity which led to this being done. The appearance of the wound was generally satisfactory. There was perhaps a slight discharge on the surface, the examination of which occasionally revealed the presence of organisms, but this did not seem to make any difference to the subsequent course of the case. His colleagues at the base hospitals who saw most of these cases after treatment reported that they were not grossly septic, and certainly their reappearance at the out-patient department, even after large punctured wounds, was much sooner than would be expected in the ordinary course of treatment. Three cases of gas gangrene were encountered; two of them received sulphapyridine by mouth and sulphanilamide was applied locally. Both recovered with suitable surgical treatment and administration of serum. In the third case, a large through-and-through wound of the thigh, gas gangrene was found at operation twelve hours after injury. The wound contained a good deal of debris, including a piece of trouser, and there were typical changes in the abductor longus and crureus. A wide surgical excision was performed, and very liberal quantities of sulphanilamide powder applied, and on recovering from the immediate operation the patient was given sulphapyridine 4 grammes four-hourly for forty-eight hours. At no time was he given any anti-gas serum, and his progress was very satisfactory. On the fifth day when the wound was examined there was no odour, the wound looked healthy, and there was no oedema of the surrounding tissues.

The use of the powder in the primary treatment of second- and third-degree burns occurring on the face, forearm, and hands had been most encouraging. The dressings were usually inspected on the fifth day, when further insufflation of powder was performed. In one severe case of burn, within five days of the sulphanilamide application, the haemolytic streptococci had disappeared, and although staphylococci and diphtheroid bacilli were present a skin graft took successfully.

Comparison of the New Compounds

Prof. A. FLEMING said that it was often assumed that the drug of choice for the streptococcal infection was sulphanilamide, for the pneumococcal sulphapyridine, and for the staphylococcal sulphathiazole. It would be truer to say that sulphanilamide was strong enough to deal with the streptococcal infection; sulphapyridine was rather stronger and able to deal also with the pneumococcal but not with the staphylococcal; while sulphathiazole was still stronger and able to deal with all three. He showed an experiment with an agar plate across which in streaks organisms had been planted, with sulphapyridine applied on the one side and sulphathiazole on the other, and as measured by the distance over which the growth was inhibited there was a definite advantage to the sulphathiazole. This was possibly a useful indication of the

power of the drug to diffuse in the body. The bacteriostatic power of the blood was only one of the things which had to be taken into account; others were rate of absorption and excretion, toxicity, and solubility, which last might well enter into the local application.

Certain substances inhibited the action of these compounds: these included large masses of bacteria, certain peptones and chemicals, and also pus fluid, which in dilutions of 1% still hindered to some extent the effect of the sulphanilamide.

On the subject of penicillin, which he first described in 1929, and which had hitherto been used only for isolating bacteria in the laboratory, it appeared that, weight for weight, it was four times as powerful as sulphathiazole and twenty times as powerful as sulphapyridine, which would make it about one hundred times as potent as sulphanilamide. It had the advantage also of not being inhibited by pus fluids or large numbers of organisms, as the other preparations were. Prof. Fleming thought that if the chemists were able to isolate and manufacture it on a large scale it might replace the sulphonamides. He added a few words in conclusion on the combined use of immunological and chemotherapeutic measures. The great advantage of combining serum with sulphapyridine in experimental gas gangrene had been demonstrated. The very small amount of immunity given by a single dose of vaccine might turn the scale.

Mr. R. MOWLEM described certain work carried out at a unit of the maxillo-facial service of the E.M.S. Burns and extensive lacerations were the chief cause of tissue loss calling for grafting. Patients ordinarily could not reach this specialized unit until a considerable time after their injury, when they were already heavily infected. The method, a variant of that of Colebrook, was as follows:

Ordinary agents, such as saline, sodium sulphate, eusol, or peroxide, were used to create a degree of cleanliness in the wound. After two or three days, when the area was reasonably clean, the powder was applied daily beneath a layer of tulle gras and saline. Only a few patients showed a sterile culture after three or four days of this treatment, but this was not a deterrent to grafting. On the morning of operation the patient was given 2 grammes of sulphanilamide by mouth two hours before being taken to the theatre. On the operating table he was given 5 c.cm. of soluseptasine. The granulations were excised, bleeding controlled, and the whole surface fairly heavily coated with powder, gently massaged into a paste with the serum in the wound. The whole area was next completely covered by the graft, and the usual pressure dressings applied and maintained for seven days. On returning to the ward the compound was given at the rate of 1 gramme four-hourly for thirty hours.

The series was too small to give any value to figures, but it numbered about 40 cases, and so far there had been only one failure. There had been no evidence of local cellulitis or systemic infection. The presence of the layer of the compound beneath the graft did not jeopardize the "take."

Dr. F. HAWKING described an experiment with guinea-pigs which was undertaken to see whether the application of sulphanilamide compound would prevent the development of gas gangrene in an experimental wound. [An account of this work is given by him at pp. 263–8 of to-day's *Journal*.]

Dr. C. A. GREEN contributed a short paper on the action of sulphanilamide therapy on antibody production, and described a long series of experiments on rabbits. Only a brief summary of his conclusions can be given here. They were that the effect of prontosil on the antistreptolysin O response to streptococcal infection in rabbits had been the subject of the investigation. No evidence of inhibition or stimulation of antibody response was obtained. The serum of non-immune rabbits under prontosil treatment had no neutralizing action on streptolysin O, nor were the antihaemolysin O titres of immune rabbits increased by the treatment. The observation, it was considered, might throw some light on the disappointing result of these compounds in the treatment of acute rheumatism as reported by some workers. If the delayed and precipitous rise in antistreptolysin O titre after haemolytic streptococcal infection of the throat was part of the rheumatic process, then prontosil therapy would neither prevent nor reduce the antibody response. On the other hand, the prophylactic use of prontosil in preventing throat infection and thereby eliminating the most common stimulus for increase in antistreptolysin O titre should be of benefit.

Major A. E. FRANCIS described in detail certain results of the procedure of treating wounds locally by the insufflation of sulphanilamide powder. The series consisted of 47 cases with 77 wounds infected with haemolytic streptococci, of which 62 wounds were infected with Group A streptococci, 3 wounds with Group C, 3 with Group D, and 3 with Group G, with six wounds infected with streptococci of undetermined type. In 31 wounds in Group A the streptococci disappeared with local therapy only; in 8 sulphanilamide was given orally as well as locally, and these also remained free; 1 case remained free after oral therapy only; 15 wounds became reinfected or resisted treatment. The 3 wounds in Group C responded satisfactorily to local or combined treatment, but the 3 in Group D resisted local therapy. In the cases infected with Group G streptococci one cleared up under local treatment only, one under oral treatment, and one under combined. The presence of much exudate, pus, sloughs, or deep crevices and pockets prevented wounds from being freed of haemolytic streptococci by the local application of sulphanilamide. The powder must be applied directly to the wound, not over tulle gras or other dressings. It was essential to place moist saline gauze over the wound, which should be covered with a layer of jaconet to retain moisture. Clinicians sometimes objected to the treatment because of the macerated appearance of the skin owing to the continued retention of moisture. If the jaconet were left off for a day or two, however, the normal appearance would be restored.

Dr. WALLESTEIN, who was prevented from developing his subject owing to the time having expired, briefly referred to work now proceeding in the laboratories on new compounds which would shortly be available for the treatment of wounds. One, of which he showed the chemical constitution, was a derivative of trypan blue linked to two sulphonamide groups.

PSYCHOLOGICAL ASPECTS OF DEAFNESS

At the meeting of the Section of Otology of the Royal Society of Medicine on February 7, with Mr. LIONEL COLLEDGE in the chair, the discussion was on "Psychological Aspects of Deafness."

Prof. HUGO FREY of Vienna said that the deaf were not a uniform group. On the one hand there were those suffering from congenital deafness or deafness acquired early in life, and on the other those known as the deafened, whose disability made its appearance in later years. Deaf-mutes formed a separate community, almost a distinct variety of *Homo sapiens*, and an interesting question in studying their psychology was to inquire into their conception of a world without acoustics. The uneducated deaf often appeared queer and not easy to handle. The educated were quite different, being careful and diligent and having great powers of concentration. It was difficult to see why in some cases the absence of hearing should not affect the patient's mentality at all, while in others it led to serious consequences. Such mental anomalies were not the consequence of the deafness, but of some other factors, one of which might be the impossibility for the deaf-mute of discharging his emotions by speech. Most deaf-mutes were from the outset not quite normal people, showing abnormalities of the central nervous system in addition to the congenital hearing defect.

Not all the deafened showed a depressive state of mind or lack of poise. As a rule the deafened overestimated the extent of their disability. There were physiological and psychological reasons for this tendency, but mainly it was due to their greatly exaggerated idea of the personal and social consequences of their defect. There were numerous occasions in daily life when normal people did not hear what they were meant to hear because the speaker was badly articulating or could not adapt his voice to the acoustic conditions. A proof of the frequency of insufficient hearing amongst normal people was the fact that all languages had their popular phrases inviting the speaker to repeat what he had said. But normal people did not mind such failures in hearing, whereas the deafened took them as a further proof of their defect and adopted a more pessimistic attitude to their situation. Occupational difficulties sometimes presented

themselves, but, on the other hand, many occupations could be undertaken successfully by the deafened. Prof. Frey thought that the depression was again insufficiently explained by the degree of isolation and withdrawal from social life which the deafened state entailed. The intellectual life of the present time, broadcasting notwithstanding, depended more on the visual sense than the acoustic; science, politics, news of every kind were conveyed mainly not by the spoken word but by the printed word reinforced by illustration. The higher the standard of culture the more important was the eye and the less, relatively, the ear. Any sense of isolation related only to the more trivial affairs of daily life, and hearing aids and lip-reading could alleviate this disability. One reason for the depression might be found in the reluctance to admit deafness and the attempt to dissimulate it, the habit of not asking for the repetition of words not understood, and the disinclination to use hearing aids.

Many years of observation had suggested an explanation for this exaggerated psychological reaction—namely, that the idea had gone deeply into the subconsciousness of these persons that they were "not right," that the inviolable integrity of their body and its organs had in some manner been impaired, and the psychic shock was increased by the thought of the future progress of the defect and its consequences. With this feeling of reduced somatic integrity and of personal inferiority, the deafened did not consider himself a complete person any longer, and felt himself excluded from the company of the normal. Many of the most depressed cases belonged to the group of otosclerotics. Yet ordinary people, although they might find it a little trouble to converse with the deafened, did not regard them as incomplete persons. The deaf person was often made a comic figure on the stage and in fiction, which suggested that deafness in the eyes of the public was not a very deep defect or of a kind to justify the thoughtful attitude shown to the blind. These reactions of the deafened person to his defect might be overcome by psychological efforts, sometimes spontaneous, at others requiring psychotherapeutic guidance. Only the neurotic deaf believed that the hearing people were the eternally happy ones. The fact that the condition was relieved by the application of mental energy and effort seemed to be the best proof of its neurotic origin and character. Finally, he pleaded that the deaf should receive not sentimental pity but an understanding of their difficulties and inhibitions.

Adjustment of the Personality to Deafness

Dr. A. B. STOKES said that deafness and its psychological associations presented many of the typical problems of psychosomatic medicine. In its basic psychological features there was no difference between deafness and any other sensory, motor, or visceral disturbance. The underlying factor mainly determining the psychological response was the personality make-up. The burden of an organically determined deafness was something to which the personality had to adjust, and the adjustment was of varying kind according to the personality. As shown by behaviour, the adjustment might be within normal limits or might be pathological, which latter could be described in terms of psychiatric categories—for example, paranoid, depressive, or anxiety states. An attempt to understand and explain in terms of psychopathological theory stood or fell by the validity of the particular theories employed. The need for personality studies, including the factor of genetic constitution, required emphasis. Under conditions of stress functional deafness might occur where there were hysterical components in the personality. This might represent a functional addition to a greater or lesser organic deficiency or a functional persistence of a transitory organic disturbance. Again the fundamental factor was the personality. Where the personality make-up was as yet immature, as in children, organic deafness might interfere with its maturation, and considerable disturbance of behaviour result. None the less, even here the constitutional genetic factor would remain as a determinant of the type of behaviour response.

MRS. IRENE R. EWING said that the psychological effects of deafness depended upon many active and reactive factors in addition to the deafness itself—the health and age, the environment and experience, the social attitude and disposition towards difficulties, the intelligence and readiness to acquire new habits, the nature of the work and interests of the patient, and his resourcefulness and sense of humour. Certain psychological problems arising from deafness might be solved by taking into account the otologist's diagnosis together with the results of pure-tone tests of hearing and tests of hearing for speech. The results of these tests showed the extent to which a deaf patient could be enabled to hear speech in all the circumstances of his daily life and the extent to which hearing could be aided by lip-reading, also how far a patient was likely to retain or lose normal speech habits. An analysis of the case histories of typical patients who had attended the clinic for the deaf at Manchester University had been made under four heads: (1) influence upon the patient's manner of thinking (that is, how far the deafness set a limit to the range of his thoughts and interests); (2) capacity to follow the spoken word; (3) ability to talk intelligibly and audibly; (4) employability. All the available evidence combined to show that the most serious psychological extent of deafness was the extent to which it restricted speech experience in each particular case. From this limitation arose all the familiar symptoms of unhappy mental life, uncertainty of action, and distrust of self often seen in deaf patients.

General Discussion

Mr. RITCHIE RODGER said that one of the difficulties with otosclerotics was in learning lip-reading. The child of 4 or 5 learned very easily if he was intelligent, but only a few mature adults ever attained proficiency.

Mr. W. M. MOLLISON said that large numbers of people became deaf after school-leaving age, and it was a pity that there were no arrangements for them to continue treatment after leaving school. Many children left school with a bilateral suppuration of the ears which would lead presently to a high degree of deafness, and there was no machinery for getting them to persevere with the treatment. He had seen a large number of recruits with discharges from the ear who had had no treatment since leaving school.

Mr. F. W. WATKYN THOMAS said that it was most important that the deafened person should be made to realize that his inability to hear conversation might be due to the fault of the other conversationalists. One of the first things he explained to such deaf people was that others perhaps did not speak properly.

Mr. A. W. G. EWING (Manchester University Clinic for the Deaf) said that a feature of the report published by the Board of Education on this subject just before the war was an entirely new scheme of classification of children with defective hearing. The hard core of the problem was the children who were so deaf as not to have talked normally, but there were other groups with lesser defects, and some of these children could remain in a normal school. Then there were children who could be educated to much more normal standards than had been the case in the past, simply fitting a hearing aid and teaching lip-reading. Deaf children were not a homogeneous group; as a whole they were not lacking in practical ability, but when tests of educational attainment were applied to them serious retardation was evident. Children who had had no opportunity to hear speech at all were two years behind at the age of 7, and by the time they reached the age of 15 their mental age was far behind because of the extent to which mental development depended upon the hearing of speech.

The second meeting of the Davyhulme Military Hospital Medical Society was held on February 13, with Colonel R. Errington in the chair. Sixty members and visitors were present and Lieut.-Colonel W. E. Underwood gave an address on gunshot wounds in the field. Further meetings, which will be announced in our Diary of Societies) have been fixed for February 27, March 13, March 27, and April 10, at 3 p.m. Medical men and women in any of the Services (including civilian) will be welcomed.

Mr. H. G. Lawrence, the Minister of Health of the Union of South Africa, recently opened the new Nigel Hospital, which has been built at a cost of £80,000 at Dunotton, Johannesburg.

Correspondence

Optimum Calcium Requirement

SIR,—In your issue of January 11 (p. 49) a paper by Dr. I Harris and Messrs. J. T. Ireland and G. V. James is published in which the conclusions are drawn that "with a high degree of certainty it can be affirmed that the calcium intake under the present dietary regime is ample" and that there is no indication for increasing it. In addition the suggestions are made that high calcium intake may be a contributing cause of arteriosclerosis and that it seriously increases the work of the kidney. These conclusions and suggestions are so unusual and so important, if established, that the evidence requires examination.

The conclusion that the dietary intake of calcium is adequate is based first on data for serum calcium in fifty-one hospital cases. Since these agree, so far as they go, with many other published findings and do not contribute to the later argument, they need not be discussed. The other evidence submitted is that of a series of metabolism studies on adult hospital patients, the absence of clinically detectable "lesions" in such persons, and the deduction, from inquiries regarding the habitual diet of patients, that their calcium intake is never below 0.45 gramme daily and in many instances is "four or five times greater" (presumably between 2 grammes and 2.75 grammes daily). The information refers only to adult hospital cases, and no account is taken of children or pregnant and nursing women.

The first, generally accepted, estimate of the calcium requirement for maintenance of adults was that of Sherman, derived from his metabolism studies, and given as 0.45 gramme daily for a man or, with a "margin of safety," 0.68 gramme. I have elsewhere reviewed the published results of calcium metabolism studies up to 1936, and from the data collected deduced an average adult requirement of about 0.55 gramme daily. The literature has been more recently reviewed by Mitchell, and his estimate for an average woman, neither pregnant nor lactating, would be about 0.54 gramme daily, and for a man up to 0.68 gramme daily for a weight of 70 kg. The requirement for equilibrium deduced by Harris from his metabolism experiments is "between 0.390 gramme and 0.579 gramme daily." He will, therefore, presumably not question the lowest accepted estimate of 0.45 gramme daily as the approximate average maintenance requirement of an adult.

When the requirement of a group of people or a whole population is estimated, the needs of children and of pregnant and nursing women must be taken into account. Stiebeling, using Sherman's estimates of requirements, calculated the average requirement of the American population to be 0.9 gramme daily, and the age and sex distribution of the American population can population is not greatly different from ours. Other estimates are those of Crawford and Broadley for the whole population of England and Wales of 0.70 gramme daily, calculated from the B.M.A. minimum diets, and 1.00 calculated from the League of Nations Technical Commission optimum diets; those of Potts, also calculated from the League of Nations diets, for different groups of households in Yorkshire, all exceeding 1 gramme daily; and my estimate of 0.765 gramme daily for the whole population. In view of these estimates, the standard requirement of 0.6 gramme daily used in *Food, Health and Income* must be regarded as conservative. Yet it is shown there that from the dietary surveys analysed the poorest 10% of the population, including 4.5 million people, of whom half are children under 14 years of age, have on the average only 0.37 gramme; the second group of 9 million, of whom about one-third probably are children, only 0.52 gramme; and the third group of 9 million, with about 2 million children, 0.61 gramme. Since the requirement of these three groups, including about 80% of the children of the country and a large proportion of the pregnant and nursing women, is greater than the average requirement of the whole population, the conclusion that half are subsisting on sup-optimal calcium intake, using a conservative standard, seems justified. The dietary survey data are amply supported by later surveys of Crawford and Broadley, Fry and Myers, Potts, Widdowson, and others. These surveys, carefully made and analysed, also indicate that high dietary intakes of 2 grammes and over must be so uncommon as to form a negligible part of the dietary history of the country.

The failure to find obvious clinical lesions attributable to calcium deficiency is not surprising. It is at least as difficult to diagnose sub-optimal calcium intake clinically as to diagnose deficiency of vitamins in any but the gross manifestations. The main effect of sub-optimal calcium intake in experimental animals, and probably in the human population, is restriction of growth or of milk yield to fit the intake. Long-continued deficiency in adults, it has been suggested (cf. Owen *et al.*), may produce senile osteoporosis, evident on x-ray examination.

The contention that there is danger to the population from increasing the calcium intake is based, first, on the calcium balances with intakes between the equilibrium level and 2.712 grammes daily. These show percentage absorptions and retentions of calcium which are so extremely high and so unlike those recorded in a much greater number of observations on normal adults that the conclusion that they are abnormal can scarcely be avoided. The results of an experiment on two rabbits can hardly be regarded as sufficient to support the suggestion that high calcium intake is a cause of arteriosclerosis. Calcium metabolism in the rabbit is known to differ from that of other mammals, especially in the ease with which its plasma calcium may be raised by dietary means. But even in rabbits attempts to produce calcification of soft tissues by increasing the calcium intake have not always been successful, and other experimental procedures have produced positive results. The inference for clinical medicine of such experiments remains obscure. Further, the statement that according to the Registrar-General's returns arteriosclerosis is "more prevalent among the affluent class" does not appear to be in accordance with the facts. The Decennial Supplement on Occupational Mortality (1931), which, so far as we know, is the only one which distinguishes between classes, indicates that the proportionate mortality at ages over 65 from cerebral vascular lesions and arteriosclerosis together, and both the standardized mortality ratio between ages 35 and 65 and the proportionate mortality at ages above 65 of both men and women from arteriosclerosis (without cerebral vascular lesion), increase to a maximum for Classes 4 and 5—that is, mainly unskilled occupations, the least affluent part of the population and that with the lowest calcium intake.

Harris and his co-workers also quote a formula for calculating the work of the kidney and estimate that increasing the calcium intake may increase the work of the kidney by over fourteen times. Using the same formula we have calculated that the effect on the work of the kidney of increasing the urinary excretion of calcium from the least to the highest figure in the balances recorded by Harris is of the order of 1 in 700. The estimates of Borsook and Winegarden also show that excretion of calcium normally accounts for less than 1 in 1,000 of the total work of concentration, and less than 1 in 700 of the total work performed by the kidney. An increase in urinary excretion to several times that at maintenance intake (if this were possible in normal subjects on a normal diet) would make an entirely insignificant contribution to total kidney work.

Hence, although from the results of their metabolism studies and clinical observations the writers may consider it advisable for certain adults to avoid a high calcium intake, they have produced no evidence that deficiency does not exist in the general population, nor any of danger to normal subjects from such calcium intakes as are considered desirable. They have in no way cast doubt on the accepted standards of requirements or the wisdom of improving the diets of the poor to those standards.—I am, etc.,

ISABELLA LEITCH.

The Rowett Research Institute,
Aberdeenshire, Feb. 1.

SIR,—In a recent paper by Dr. Isaac Harris *et al.* (January 11, p. 49) on calcium requirement unorthodox and conflicting statements have been made, the accuracy of which warrants a careful inquiry in view of the importance that may be attached to their findings and interpretations at the present time. It is proposed to deal with their paper under various headings.

1. Calcium Balance Studies.—A comparison of the calcium intake and output is a recognized method of determining the calcium metabolism of the body. In normal people about 76% of the total calcium is excreted in the faeces and only 24% by the kidneys. Dr. Harris and his colleagues have reported results where the calcium excretion was greater in the urine than in the faeces. The calcinuria varied from 53 to 73% of the total calcium excreted, with an average figure of 64%. There is one conclusion, assuming the collection of the specimens was accurate, that the cases studied were not normal healthy subjects.

2. Minimum Calcium Requirement.—It has been established by Sherman and his co-workers that the minimum or maintenance calcium requirement is 0.45 gramme daily. On what grounds do Dr. Harris and his colleagues state, "the minimum calcium requirement is probably lower than" 0.45 gramme daily? It must be remembered that calcium balance studies, on which data the minimum calcium requirement was based, are carried out in hospitals with carefully prepared balanced diets and under ideal experimental conditions. It is more than probable that diets taken at home are not balanced, with the result that a too acid or too alkaline food mixture promotes increased excretion and decreased absorption respectively. The figure of 0.45 gramme daily is a conservative minimum when considered in the light of home-feeding and not too high, as Dr. Harris *et al.* state.

3. Optimum Calcium Requirement.—Dr. Harris *et al.* state, "We may take it that the calcium intake covering optimum requirements is one with neither a negative nor a positive balance." That statement is wrong. Many years ago Sherman took great pains to point out the importance of differentiating between minimum (or maintenance) on the one hand, and optimum (or ideal) calcium requirement on the other. He stressed that 0.45 gramme calcium daily was the minimum of actual need and not the normal allowance. In children the optimum requirement is 1.0 gramme daily, and this results in the retention of 0.01 gramme of calcium per kilogramme of body weight each day. In the adult the intake may with safety fall to 0.70 gramme daily. There is not the space to quote in detail work proving the importance, particularly in children, of having more than the minimum intake of calcium. Failure to do this adversely affects growth, weight, maturity, powers of reproduction, onset of senescence, and, so very important, the health of the next generation.

4. Evidence of Calcium Deficiency.—Dr. Harris *et al.* state, "One of us has been looking for years for cases of calcium insufficiency in an extensive hospital practice . . . but not one case was found. The dental surgeon makes *x*-ray examination of the teeth as a routine; he too was unable to draw attention to one case of calcium insufficiency." It is improbable that Dr. Harris or the dentist will detect calcium shortage (the type met with when people live on calcium-poor diets) clinically or by *x*-raying the teeth. To quote Sherman: "Normal growth does not mean normal development. A calcium-poor condition of the body may coexist throughout much or all of the period of growth with normal increase of height and weight and with every appearance of good health as indicated by physical examination." Marked calcium loss, if it has been of long duration, can eventually be demonstrated by an osteoporosis of the skeleton, but before this occurs evidence may be obtained by a study of the calcium balance. Dr. Harris *et al.* in their table on the calcium balances of so-called normal people studied in Liverpool *demonstrate in fact that there is a calcium insufficiency present.* In normal people an intake of calcium over 1 gramme daily does not result in any further increase of calcium retention. When any further increase does occur it is evidence that there is a calcium-poor condition of the body. In Dr. Harris's cases, as the daily calcium intake increased from 0.824, 1.791, 1.990, 2.566 to 2.712 grammes, so the daily retention increased from 0.265, 0.759, 1.393, 1.735, to 1.980 grammes—evidence in fact that these subjects are in a state of calcium deprivation.

5. Calcium Overdosage.—In support of the dangers of calcium overdosage the authors tabulate experiments on *three rabbits.* No protocols are given of dosage or duration of experiments. They found that a calcium-rich diet in rabbits produced an increased calcium content of the aorta. Such findings are in conflict with the views of Kost, while Emmerich and Loew, Gaunt Irving and Thomson, Orr Thomson and Garry, Coward Kassner and Waller, Evvard Dox and Guernsey, and Sherman and his co-workers showed that animals actually benefited greatly from a high calcium intake. Against this mass of scientific evidence, Dr. Harris *et al.*, after observations on only *three* rabbits, would have us believe that all manner of pathological lesions will arise in human beings if they take too much calcium. As previously stated, however, even if the calcium intake exceeds the optimum of 1.0 gramme daily *no further retention of calcium occurs unless the body through deprivation of that mineral so desires and requires it.*

6. Average Intake of Calcium in the Home.—The large majority of our staple foods contain little or no calcium, so it is quite possible for a dietary to be abundant, nutritious, and varied, yet be calcium-poor. Excluding only milk and cheese, an ordinary diet averages about 0.200 gramme calcium daily. We are assured by Dr. Harris *et al.* that in Liverpool "in a good many instances" the calcium intake daily is 1.80 to 2.25 grammes, so we must assume that these people consume daily two and a half to three pints of milk, or six ounces of cheese or variations thereof. I wonder how many adults now consume these proportions of milk and cheese. Have Dr. Harris *et al.* irrefutable data to support their statement that "a considerable amount of evidence exists that large sections of the population are in the habit of using too much of the type of food which is rich in calcium"? I would like to feel assured that Dr. Harris *et al.* have that data, for the danger exists *not with too much calcium but too little.* But the patients Dr. Harris used for his calcium balance studies present the very opposite features of those having too much calcium in their diets. I would like to emphasize that in order to reach the optimum calcium intake the diet must contain milk and/or cheese, and if these foodstuffs are not available one alternative is to fortify with calcium a staple food such as bread.

The paper by Dr. Harris *et al.* cannot be looked upon as a serious contribution to the literature on calcium metabolism. It is lacking in essential experimental details, there is only one reference to previous work on calcium metabolism, of which there is a wide literature, and its conclusions are not accurate. In wartime the nation's nutrition is a very important factor, and not the least is the danger of calcium lack, which is a problem even in peacetime.

Briefly summarizing the points of this letter:

1. The calcium balance studies of Dr. Harris *et al.* are not those of normal healthy people.
2. The *minimum* calcium requirement is 0.45 gramme daily.
3. The *optimum* or ideal calcium requirement is 1.0 gramme for children and at least 0.7 gramme for adults.
4. Dr. Harris *et al.* have clearly demonstrated by their own results that the people they studied in Liverpool are not getting enough calcium in their diets.
5. No ill can result from overdosage with calcium, as the body reaches its maximum retention on an intake of 1.0 gramme daily, which is the optimum requirement of the body.
6. To reach the safety limits of the body's requirement for calcium a diet needs milk and/or cheese, and failing this then additional calcium must be taken.—I am, etc.,

J. DOUGLAS ROBERTSON.
The Middlesex Hospital, London, W.1, Feb. 17.

Vitamin K in Liver Damage

SIR,—I have read with interest the article by Mr. Michael J. Smyth on exploration of the common bile duct for stone (January 25, p. 111). He states: "A certain proportion of surgeons have always been chary about operating upon jaundiced patients, because of the danger of haemorrhage—not vigorous haemorrhage from any particular arteries but a

continuous steady ooze from the tissues which is apt to be continuous after operation in such cases. This lack of clotting power is due to prothrombin deficiency and can be corrected by giving vitamin K in combination with bile salts by mouth before operation, the bile salts being necessary for the absorption of the vitamin from the intestine." Statements such as these (which are common in the literature) give one a false sense of security in the efficacy of vitamin K. The vitamin undoubtedly has a large range of usefulness, but it is without effect in the presence of liver damage.

"Complete obstruction of the common bile duct is extremely damaging to liver function. The degree of hepatic damage is proportional to the length of time that the bile has been dammed back. It follows that obstructive jaundice should always be relieved at the earliest possible moment. Failure to appreciate this is responsible for many post-operative deaths in spite of good surgical technique. If, in a case of jaundice the bleeding time is prolonged and it fails to respond to vitamin K there is strong evidence of hepatic insufficiency. The only way to deal with these cases is by large plasma or blood transfusions before and after operation to make up for the prothrombin deficiency.

The following case illustrates these points: a patient with a five-weeks history of obstructive jaundice was found at operation to have white bile in the biliary passages and a calculus obstructing the lower end of the common bile duct. The calculus was easily removed and the common bile duct was drained with a Maingot's T-shaped tube. In spite of a week's treatment with kapilon 1 c.cm. daily, bleeding time before operation was still double the normal, and so a pint of blood was given before taking the patient to the theatre. After the operation the patient oozed continuously from the wound and six pints of blood were required to restore the haemoglobin to its pre-operative level. Not until four pints had been introduced did the oozing stop. The patient died ten days after the operation from hepatic failure.—I am, etc.,

Middlesbrough, Feb. 4. R. N. HERSON

Effort Syndrome

SIR,—In reply to Surgeon Captain Lambert Rogers's comments (January 25, p. 134) on my letter (December 28, p. 915) I frankly admit that hyperactivity of the thyroid gland cannot be excluded as a possible aetiological factor either in the two cases quoted by me or indeed in a considerable proportion of the cases described under the generic title of "D.A.H." or "effort syndrome." I regret that this aspect of the matter did not receive the emphasis it merited, all the more so as even in the post-war years (1920–6) the possible rôle of thyrotoxicosis in the aetiology of this syndrome was being increasingly recognized. More particularly perhaps the conception that there might be many degrees of thyrotoxicosis falling short of the clinical entity known as Graves's disease seemed about that time to be coming to the fore. Even so I submit that this in no way invalidates my main thesis as to the importance of the mental or psychological background in the overwhelming majority of these cases. Without in the least depreciating the value of surgical intervention in selected cases it could, one imagines, scarcely be applied as a general procedure in a condition which was so widely prevalent as in the last war. It must be remembered, too, that although in my experience the majority of these cases are unlikely to qualify for military service it is quite conceivable that they may react favourably to a return to normal peacetime conditions, and this without resort to any specific surgical treatment. In the absence of any spectacular increase in the male incidence of Graves's disease during the last twenty years it would rather appear that such spontaneous recovery is the rule rather than the exception. The pitfalls involved in the verbal presentation and still more in the diagnosis of a case on such data are notorious, and these Captain Rogers generously acknowledges, but I imagine that neither of the cases referred to would on actual encounter have suggested themselves as suitable for surgical intervention. It is unfortunate perhaps that a third case quoted in my original letter but excluded owing to exigencies of space presented no signs in the least suggestive of thyrotoxicosis but exhibited in marked degree those abnormal nervous and mental characteristics so typical of these cases.—I am, etc.,

Leeds, Feb. 3. J. E. MIDDLEMISS.

Treatment of Jaw Injuries

SIR,—Squadron-Leader H. E. H. Tracy's letter (January 25, p. 136) must have been written without knowledge of the existing arrangements for the treatment of jaw and facial injuries.

Your readers will no doubt have seen the report of the Army Advisory Committee on Maxillo-Facial Injuries and I can assure them that the vital importance of early treatment is fully recognized. Happily the number of cases has not yet been such as to justify the establishment of special maxillo-facial hospitals over-seas, but a suitably staffed section of a general hospital was set aside for the reception and treatment of maxillo-facial injuries in France and another is actually working in the Middle East.

Early and close co-operation between the surgeon and dental surgeon is regarded as essential, and, before being posted to a field medical unit, each Army dental officer attends a special course of instruction in the treatment of maxillo-facial injuries. These courses are given at the Army Dental Corps School of Instruction and have proved to be of the utmost value particularly as the services of a dental officer are available as far forward as the divisional field ambulances.

In this country all cases, whether Service or civilian, are treated in the special centres set up under the Emergency Medical Service scheme, where again the advantages of grouping and team work have been fully recognized.—I am, etc.,

D. CLEWER, Major-General,
The War Office, Feb. 8. Director, Army Dental Service

Suspected Case of Chronic Meningococcal Septicaemia

SIR,—I was interested to read Dr. A. Graham Porter's clinical memorandum (February 1, p. 158), and would wish to stress the point he makes—namely, that this disease is "probably commoner than is supposed and may become increasingly so because of the high incidence of cerebro-spinal fever which has been maintained throughout the year." In the *Journal of the Royal Army Medical Corps*, July, 1926, I reported a short series of these cases and emphasized the importance of the rash as a diagnostic feature. This rash may be described as a recurrent erythema multiforme distributed sometimes over the whole body but showing a predilection for the limbs. On the forearms and the shins particularly it is characteristic of erythema nodosum. There seems to be no doubt that this rash is a septicaemic manifestation. The organism was recovered from the centre of a nodule in one of my cases, and the intensity of the rash tends to be in proportion to the severity of the fever.

The disease may run a very prolonged course, and in one of my cases persisted for two years and four months, but in those days we did not know of sulphapyridine. It is all the more essential, therefore, to make an early diagnosis and to this end it is important that the association of erythema nodosum with meningococcal infection should be more generally recognized. May I repeat, therefore, what I said in 1926: "Given a case of erythema nodosum, suspect meningococcus infection."—I am, etc.,

J. C. KENNEDY, M.D.,
Feb. 7 Colonel, late R.A.M.C. (ret.); sometime Consulting Physician to the Army.

"Egyptian Tummy"

SIR,—I have read the correspondence in your columns on this malady, and would like to add my comments.

In Alexandria during the last war attacks of diarrhoea and vomiting, called "Gippy tummy," were very common in our camp at Ras el Tin. The temperature in Alexandria is equable, and in my opinion not conducive to causing chills. I admit that sudden chills can predispose to gastro-intestinal disturbances: nevertheless I am certain in my own mind that the so-called "Gippy tummy" among our soldiers in Alexandria was due to food-poisoning infections of the typhoid–dysentery—almonella groups. There were in addition protozoal infections caused by amoebae and intestinal flagellates. These facts were brought to light by the team of workers at the Central Laboratory, Alexandria—namely, Major Fergusson, professor of pathology, Cairo; T. J. Mackie, now

he has easy entry to the household. He would thus have an associated power of action as regards the health and surroundings of the members of the family, and thus he, the family specialist, would come to have a most important individual and national responsibility.

Given proper conditions of time and service, institutional facilities, and easier access to patients, the general practitioner would have particular advantages and functions that would make him not superior or inferior to, more important or less important than any other section of the profession, but a man with special functions indispensable to a complete and effective national service. With this friendly and intimate association of family doctors with all sorts and conditions of the people, this wide outlook and independence of thought, the sum total of their influences, medical, social, economic, and political, using these words in their wider sense, must be great. It would be a calamity to throw away this power for good.—I am, etc.,

Westbury, Wilts, Feb. 12. CHARLES E. S. FLEMMING.

SIR,—There must be many medical men like myself—preoccupied with other matters—to whom the proposal of the B.M.A. to set up a commission to settle our future has come as a shock. I freely concede, of course, the academic distinction of the members proposed for the Commission, but is there one among them whose future is not assured whatever happens to the rest of the profession? Every one of us will, of course, be affected to some extent, but it appears to me that the ones who should have most say in the matter are the ones who have most to lose.

Further, I do not believe that the constitution of the B.M.A. is such as to enable it to deal with a question of this magnitude. Surely it is a question which should be thrashed out on parliamentary lines, and not settled for us by the usual medical oligarchs. In my opinion it is high time that an official "opposition" should be organized. Nowadays if a man disagrees with the official policy of the B.M.A. he expresses his disapproval by ceasing membership; I happen to come from a district in which a large number of medical men have done so. In the absence of an organized opposition there is not much else he can do. But can the B.M.A., which professes to represent the profession, afford to allow these men to disenfranchise themselves in this way merely because they disagree with the opinion of the majority? I am not going to argue here about why they do it: I am merely concerned with the fact that they do, and that there is a growing opposition to B.M.A. methods both within the fold and outside it. I believe that unless the B.M.A. takes cognizance of this fact while there is still time and before irrevocable decisions are taken it will run the risk of disrupting the whole profession, and this Commission is the rock on which it will do it. It will be bad for the profession, but fatal for the B.M.A.

Has the B.M.A. sufficient democratic spirit to acknowledge and rope in the opposition, to organize it and subsidize it, and unite the profession over the heads of party disputants? The B.M.A. might then justly claim to represent the profession and could reconsider this question of the Commission with a better prospect of getting its decisions accepted. Is the B.M.A. unaware of this opposition, or does it wish to ignore it? Dare I suggest that there is an "opposition" organization ready made? No, I do not belong to it.

The grandfatherly leader in the *Journal* of January 4 (p. 19) I find definitely alarming. If the B.M.A. really believes that "the present war found the profession well prepared to play its essential part in the struggle" it is likely to find its self-complacency rudely disturbed when the men now on service return home. The last word has by no means been said on such things as the Protection of Practices Scheme and on the men whose services were indispensable at home. Meanwhile it would appear to be our bounden duty to achieve unity in the profession by common agreement, and not, by ignoring opposition, to put up a semblance of it.—I am, etc.,

C. J. STOCKER,
Glasgow, Feb. 6 Lieutenant-Colonel, I.M.S.

SIR,—Every member of the profession recognizes the necessity for reform and the inevitability of post-war reorganization. This is, however, an extremely complex problem, in which doctors, with their various sectional interests, are not the only affected parties.

It is essential for the profession as a whole to discuss these matters, but whether it is possible or desirable to attempt to formulate a policy to meet political and economic conditions which are at present unknown is a different matter. Certain it is that the method by which this Commission has been chosen is open to grave objection, and that this is a democratic method of ascertaining the views of the rank and file of your members is open to doubt.

When the time is suitable the appointment of a parliamentary commission is inevitable, and to such a commission your Medical Planning Commission will be invited to state its views. If these views, which will represent nothing more than the majority vote of what is for all practical purposes a self-appointed committee of forty members, are presented as the decided policy of the whole profession, then the future of the profession will be gravely compromised.—I am, etc.,

London, W.1, Feb. 8. R. BLAIR GOULD.

SIR,—Dr. Charles R. Gibson's letter (February 1, p. 171) should be read by every home doctor. It is democratic and in tune with the aims for which the Allies are fighting. In this Division we have elected a committee for this purpose whose decisions will be presented to the Division. This *ad hoc* committee is representative of various interests—general practitioners of different ages, medical officers of health, hospital service, group medical practice, extension of national insurance. Documents summarizing some services have been circulated: each member is to set forth briefly his own ideals and the framework of his method of attaining them. The next meeting (to be held on Sunday) has for its subject State Medical Service. This appears to be almost identical with the recommendation by Dr. Gibson.—I am, etc.,

Teddington, Feb. 5. P. W. L. CAMPS.

Academic Status of Radiology

SIR,—In a letter published in your issue of January 25 (p. 133) Dr. Ffrangcon Roberts writes: "No one will deny that the advent of radiology in its twofold purpose has been one of the few great revolutions in medicine. In spite of this radiology has acquired in this country no academic status. It has no College of its own. Of university chairs there are none; of lectureships only one or two. In this respect we are lamentably behind all other great countries."

It is true that there is now no professorship in radiology in this country, but I feel that the rest of the paragraph quoted may give a wrong impression of the academic status of radiology in this country. There are at least fourteen official university lecturers in radiology in the Provinces, Scotland, Wales, and Ireland. In London there are no lecturers in radiology listed in the London University staff, but in the great majority of the medical schools (which rank as official schools of the University) the senior member of the radiological staff ranks as a lecturer, and is recognized by the University as an official teacher of radiology.

It is true, also, that there is no College of Radiology, but there is a Faculty of Radiologists with similar functions. The Faculty grants a higher qualification in radiology, the Fellowship, which is taken by examination and thesis. Some of the examiners for this Fellowship are nominated by the Royal Colleges of Physicians and Surgeons. It is an index of the status which the Faculty, although but recently incorporated, has already achieved, that it is one of the few bodies entitled to nominate a representative on the Medical Planning Commission of the B.M.A.—I am, etc.,

S. COCHRANE SHANKS,
London, W.1, Feb. 10. President, Faculty of Radiologists.

Dry Clothing

SIR,—It is well known that absorption of water by dry clothing produces a remarkable amount of heat. I dealt fully with this subject in "The Science of Ventilation and Open Air Treatment" (Med. Res. Cncl. Spec. Rep. Ser. No. 52, p. 233, 1920). Dr. C. K. Vartan (February 8, p. 219) failed to get the effect because his flannel was not dry. To demonstrate the effect fit a cork, with a hole bored through it, to a small bottle, having passed the bulb of a thermometer, round which the material has been wrapped, through the cork. Warm the

bottle in front of a fire so as to dry the material, the thermometer reading about 130° F. Then remove the bottle from the fire and allow the thermometer to return to room temperature. To effect this quickly the bottle can be cooled in water. Then take out the cork with the thermometer, and suspend it in room air. The material absorbing moisture from the air will now heat up the thermometer about 10° F. Clothes aired in a hot cupboard and put on dry will warm the body by taking up moisture from it, hence the comfort of dry clothes. Pleated cotton-wool, rabbit's fur, sheep's wool, flannel and knitting wool all produced much the same rise in temperature.—I am, etc.,

Chalfont St. Peter, Feb. 13. LEONARD HILL

Naming of New Drugs

SIR,—In view of the editorial on "The Rationalization of the British Drug Industry" which appeared in our issue of December 21, 1940, we feel that we are entitled to draw your attention to the fact that the B.D.H. have ever set their face against the policy adopted by foreign firms, and one has been followed by some British firms, of unnecessarily coining names for their own particular brands of medicinal products the manufacture of which is not their exclusive property. I enclose a copy of a slip entitled "B.D.H. Naming Policy" which was issued to the medical profession just a year ago.—I am, etc.,

CHARLES ALEX. HILL
London, N., Jan. 7. Managing Director, The British Drug Houses Ltd

*** This letter has been withheld from publication until now at the writer's request.—ED. *B.M.J.*

Sales of Papworth Industries

SIR,—Sir Arthur MacNalty in his admirable and sympathetic account of the life and work of Sir Pendrill Varrier-Jones (February 8, p. 221) states that the sales of the Papworth Industries amount to well over £88,000. This must relate to some years past, for the figures for 1940 reached £363,434, while those for the associated factories at Enham amounted to £127,622, so that the whole totalled nearly half a million—a great achievement.—I am, etc.,

London, W., Feb. 17. W. LANGDON-BROWN.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Faculty Board of Medicine has co-opted Sir Walter Langdon-Brown until December 31, 1941. It has also appointed Dr. W. L. H. Duckworth, Prof. H. R. Dean, and Dr. G. S. Graham-Smith to be members of the Appointments Committee of the Faculty for the years 1941 and 1942.

The following candidates have been approved at the examination indicated:

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—*Part I:* M. Altmann, R. D. Caton, A. Elkeles, J. E. Glasgow, Mrs. Grace M. Griffith, M. Halberstaedter, P. C. Phelps.

UNIVERSITY OF MANCHESTER

Dr. R. E. Lane has been appointed Lecturer in Medicine.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council held on February 14, Mr. F. W. Holdsworth, M.Ch., F.R.C.S., was appointed Honorary Lecturer in Orthopaedic Surgery.

Prof. G. A. Clark was appointed representative of the University on the drafting committee to be set up to draft a constitution of the proposed regional committee in connexion with the Regionalization Scheme of the British Hospitals Association and the Nuffield Provincial Hospitals Trust.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Arnott and Erasmus Wilson Demonstrations

The following Arnott and Erasmus Wilson demonstrations of specimens in the museum, open to advanced students and medical practitioners, will be given in the theatre of the College, Lincoln's Inn Fields, W.C.: February 24, Mr. R. Davies-Colley, inflammation of bone: February 28, Dr. A. J. E. Cave, anatomy of the cervical plexus: March 3 and 10, Surgeon Rear-Admiral C. P. G. Wakeley, tumours of the alimentary tract: March 7, Dr. Cave, anatomy of the brachial plexus: March 11, Mr. Davies-Colley, tumours of the breast: March 14, Dr. Cave, innervation of the body wall. All the demonstrations begin at 3 p.m.

At a meeting of the Council of the Royal College of Surgeons of England, held on February 13, with Sir Hugh Lett, Bt., President, in the chair, the Hallett Prize was presented to Mr. J. D. T. Jones of Durham University.

Mr. E. K. Martin of University College Hospital was re-elected a member of the Court of Examiners.

It was reported that Mr. John Hunter and Mr. A. Wilfrid Adams had accepted the invitation of the Council to act as representatives of the College on the Medical Planning Commission.

Mr. Ernest W. Hey Groves was re-elected as the representative of the College on the General Medical Council.

Dr. A. P. Cawadias was appointed Thomas Vicary Lecturer for 1941.

It was decided to recognize the post of second surgical officer at the Royal Gwent Hospital, Newport, under paragraphs 21 and 23 of the F.R.C.S. Regulations.

Diplomas

Diplomas of Membership and Diplomas in Public Health and Medical Radiology were granted to the candidates whose names were printed in the report of the meeting of the Royal College of Physicians of London published in the *Journal* of February 8 (p. 223).

The Services

AWARDS AND MENTIONS IN DISPATCHES

M.B.E. (Military)

Lieut. Robert Elmer Horton, R.A.M.C., has been appointed an M.B.E. (Military Division) for conspicuous gallantry in carrying out hazardous work in a very brave manner.

G.M.

Lieut. John Richard Monks, R.A.M.C., has been awarded the George Medal for conspicuous gallantry in carrying out hazardous work in a very brave manner.

Mentions in Dispatches

Major M. H. Wace, I.M.S., and Captain B. A. Coghlan, E.A.A.M.C., have been mentioned in dispatches for distinguished services in the field in Somaliland.

Corrigendum

In the list of officers whose names have been brought to notice in recognition of distinguished services in connexion with the operations in the field, March to June, 1940, published in the *Journal* of January 4, the initials of Captain O. M. Walker, R.A.M.C., should read Captain D. M. Walker, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Wounded

Temporary Acting Surgeon Lieutenant-Commander Wolsey Cornwall Sloan, R.N.V.R.

ROYAL ARMY MEDICAL CORPS

Lieut. JAMES CUNNINGHAM is included as "Died" in an Army Casualty List published on February 14. He was educated at Glasgow University, where he graduated M.B., Ch.B. in 1925, when he joined the British Medical Association.

Lieut. JAMES IAN MCCONNELL, who was posted as "Missing, believed Prisoner of War" in the *Journal* of June 1, 1940, is

now reported as having died in an Army Casualty List published on February 14. He was educated at Durham University, graduating M.B., B.S. in 1939, and had held the post of house-surgeon at the Royal Victoria Infirmary, Newcastle-upon-Tyne. His home was at Tynemouth, Northumberland.

Wounded

Lieut. James Morton Muir.

Prisoner of War

Lieut.-Colonel Donald McMichael Crawford.
Lieut. Abraham Lemel Karstaedt.
Lieut. Norman Bryan Walker.

DEATHS IN THE SERVICES

Colonel GEORGE DANSEY-BROWNING, C.B.E., died at Sidmouth on February 2, and the following account of his career has been sent by Major-General Sir G. Guise Moores, K.C.B.: George Dansey-Browning was a fine type of Army medical officer, one who gave to the end of his days a full devotion to the soldier and his interests. Born in 1870, he was educated at the Lycée l'Orient, Rennes, and the University of Paris. He was an accomplished French scholar. Dansey-Browning was a student of Westminster Hospital, taking the diplomas of M.R.C.S., L.R.C.P.; he then in 1894 joined the R.A.M.C. by open competition. It is difficult to recall any period of his forty-five years' work for the Army in which he found a respite from his labours. At his homecomings in his early career from India, China (medal), Egypt (medal and Order of Osmanieh), he occupied his leisure and leave in taking the diplomas of D.P.H., D.T.M., and the M.R.C.P. While in Egypt he served on the Sudan sleeping sickness commission During the last war Dansey-Browning was appointed M.O.H., Gibraltar. His investigations were chiefly concerned with diseases incidental to a Mediterranean garrison and those brought in by the varied and shifting population of a great maritime port. For his services he was awarded the C.B.E. and the French medal for epidemics. The war over, he went to India as A.D.M.S. of the Meerut and Lucknow Divisions, and retired in 1922. Then followed an appointment as director of the newly formed Enham Village Centre for disabled soldiers This accomplished, Dansey-Browning elected to take a retired pay billet as medical officer to the R.E. training camp at Longmoor; here he gave up all else in unstinted devotion to the soldier and his family. He formed centres for dealing with the welfare of mother and child with outstanding merit and success. The age limit stepped in and his work at Longmoor ended, but his love of his profession enabled him to carry on in London at the Regent's Park Barracks, and at the oncoming of the new war in 1939 with the Irish Guards Training Battalion. In December last the physical ills that flesh is heir to became manifest and the labourer's task was o'er, though undaunted was the spirit. Dansey's ways were ways of gentleness, with the simple piety of devotion to the sick and needy, and he will be long remembered as a well-tried and beloved physician.

Lieut.-Colonel CHARLES EDWARD PERCY FOWLER, O.B.E., R.A.M.C. (ret.), died after a long illness at Wickham Bishops, Essex, on January 21, aged 74. He was born on January 27, 1866, at Milverton, Somerset, and was educated at Bristol and at St. Mary's Hospital, London, qualifying M.R.C.S., L.R.C.P. in 1889. He was granted the diploma of F.R.C.S. two years later and took the D.P.H. of the University of Cambridge in 1894. He entered the Army as surgeon lieutenant in 1893, became major in 1905, retired in 1914, rejoined for service in August, 1914, and received a brevet lieutenant-colonelcy in 1917. He served as assistant professor of hygiene at the R.A.M. College from 1903 to 1907, as medical officer of health and sanitary officer, Gibraltar, from 1907 to 1912, and then for a year as instructor in the Army School of Sanitation. In 1909 he accompanied a British mission to Fez, Morocco. During the war of 1914–18 he served as A.D.M.S. of the Egyptian Expeditionary Force and subsequently as D.A.D.M.S. at Aldershot.

Surgeon Captain FRANCIS BOLSTER, C.M.G., R.N. (ret.), died at Biggleswade on February 11. He was educated at Trinity College, Dublin, as an undergraduate was resident pupil at Sir Patrick Dun's Hospital, Dublin, and graduated M.B., B.Ch. in 1896, proceeding M.D. in 1905. Entering the Royal Navy soon after qualifying, he became surgeon commander in 1911 and surgeon captain in 1924. He served during the war of 1914–18, and was present at the Battle of Jutland and received the medals and the C.M.G. In 1919 he was awarded the West London triennial medal for heroism on a sinking ship during the Battle of Jutland. He had been a member of the British Medical Association for thirty-four years.

Obituary

JAMES ALLAN, M.D., D.P.H.

Dr. James Allan, who (as recorded in last week's *Journal*) died at his home in Leeds on January 28, was for forty-four years medical superintendent of St. James's Hospital (formerly the Leeds Union Infirmary), a post from which he retired in 1925.

Born in 1853, the son of William Allan, farmer in Birnie, near Elgin, he was a member of the 1870–4 arts class at King's College, Aberdeen, and graduated in medicine, with honours, in 1877, taking his doctorate three years later. After spending nearly two years as house-surgeon and house-physician in the Northern Hospital, Liverpool, he was appointed in 1879 assistant medical superintendent of the Wandsworth and Clapham Union Infirmary. In 1881 he was appointed medical superintendent of the Leeds Union Infirmary. During his long tenure of this office he played an important part in the developments which took place in this institution. Perhaps his most outstanding contribution was the great improvement which he effected in the nursing service. The nursing staff at the time of his appointment numbered nine, and they were untrained. Almost their sole qualification for acceptance as nurses was that they should be able to read and write and understand written directions for the administration of medicines. Some years later the systematic training of nurses was instituted, Dr. Allan himself giving the lectures, and the examinations, both written and *viva voce*, being conducted by Dr. Wardrop Griffith. As a result, the whole status of the nursing staff was raised and the care of the sick poor entered upon a new phase.

In all this work Dr. Allan had a strong supporter in Mr. (now Sir James) Ford, clerk to the Leeds Guardians, with whom he worked in close collaboration during the whole period of his service. As superintendent Dr. Allan's outstanding characteristics were conscientiousness and diligence in the performance of his duties, and he was held in the highest esteem by the members of his committee. Physician and surgeon too, it was only under pressure that he finally agreed to the appointment of a consulting surgeon on the staff. Prior to this he had done most of the operating himself. It was in the post-mortem room, however, that he was really in his element. After a long and arduous day's work in the wards, the operating theatre, and the office, he would regularly start work in the post-mortem room at 10 o'clock at night and carry on into the small hours of the morning—and he expected his residents to attend these seances!

Dr. Allan was elected a member of the Leeds and West Riding Medico-Chirurgical Society in 1881, and he occupied the presidential chair in the 1907–8 session. He was a most regular attendant at its meetings and at those of the Leeds Pathological Club, of which he was an original member and zealous supporter. His connexion with the British Medical Association was a long and honourable one. He was elected a member in 1882 and for twenty-six years (1905–31) he was honorary secretary of the Leeds Division. During most of this time he was also a member of the Representative Body, and in 1920–1 was chairman of the Yorkshire Branch. He married Miss Elizabeth Williams in 1882 and is survived by three daughters. Three of his grandchildren are students of medicine; a fourth is with the Army of the Nile.

Dr. Allan was a man of fine physique and dignified presence. Austere and reserved in demeanour, he was tenacious of his

opinions and a difficult man to move once he had made his mind. With all this he possessed a quiet sense and a critical faculty which on occasion could find witty and even sarcastic utterance. Those who knew him to be his friends retain the memory of an upright fearless man, who faithfully served his profession city of his adoption throughout the active years of He was buried in the churchyard of his native village where he lies with many generations of his forebears.

W. H. C. NEWNHAM, M.A., M.B., M.R.C.S.

We regret to announce the death of Dr William Henry Christopher Newnham, which took place at Clifton on January 11; he was in his eighty-fifth year. For many years Dr. Newnham was one of Bristol's leading medical men. He was born at Wolverhampton, where his father practised for many years. From Wolverhampton Grammar School he went up to Genville and Caius College, Cambridge, in 1874, graduating B.A. and proceeding to M.A., M.B. in 1883. He had obtained the M.R.C.S. diploma in 1880. After leaving Cambridge he became a student at Guy's Hospital, where he held the posts of house-surgeon and resident obstetric officer. His next appointment was resident medical officer at the Evelina Hospital for Children. He went to Bristol as house-surgeon at the Bristol General Hospital in 1887. At the end of three years, having decided to specialize in obstetrics and gynaecology, he was appointed to the post of assistant obstetric physician to the hospital, and on the death of Dr. Aust Lawrence in 1897 he was appointed obstetric physician; retiring under the age limit in 1923. He soon acquired an extensive practice in his specialty, and played a prominent part in the development of the obstetrical and gynaecological department of the Bristol General Hospital.

Dr. Newnham was devoted to his hospital work. He took the greatest interest in his patients, usually visiting them every day. Even after his retirement he frequently came down and did a round of the wards, and was always warmly welcomed by the patients and hospital staff. Dr. Newnham was a former president of the Bristol Medico-Chirurgical Society, a Fellow of the Royal Society of Medicine and a member of the British Medical Association for forty-nine years. His principal relaxation was the theatre and a game of bridge. He married a daughter of the late Mr. William C. Beloe of Clifton, and has two daughters. He suffered a grievous loss when Mrs. Newnham died several years ago from which he never really recovered. Until a few weeks before his death he was very active and took the greatest interest in everything. He will be greatly missed by a large circle of friends in Clifton.

ELIZABETH HURDON, C.B.E., M.D.

The death of Dr. Elizabeth Hurdon, which occurred in January at her home in Exeter, will be mourned by her many friends and colleagues, both in Great Britain and America. She was known as an outstanding personality in the medical profession for her work on the pathology and treatment of cancer in women and her brilliant success as the first director of the Marie Curie Hospital, London.

She was born in Bodmin, Cornwall. *Early in life* she migrated with her family to Canada, where she studied medicine at the University of Toronto, taking her M.D. degree in 1895. She then went to the Johns Hopkins Hospital, Baltimore, where she studied under Sir William Osler, later being appointed assistant to Dr. Howard Kelly in his gynaecological department, gaining thus a very thorough knowledge of pathology and gynaecological surgery. *She settled in private practice* in Baltimore, remaining there until the last war. In 1915 she joined up with the rank of Captain, R.A.M.C., and served in Malta and later in Salonika, where she had the charge of [illegible] beds reserved for cases of dysentery, and was able to [illegible] value of anti-dysenteric serum. Finally she was [illegible] to military hospitals in Greenwich and Woolwich [illegible] being demobilized.

[illegible] the late Dr. Helen Chambers conceived the idea [illegible] a hospital for the clinical research and treatment [illegible] in women. A Cancer Research Committee was [illegible] consisting of the senior gynaecological surgeons of [illegible] Garrett Anderson, the South London, and the [illegible] Hospitals, and those of the gynaecological unit [illegible] Royal Free. A loan of radium was obtained through [illegible] Medical Research Council from the Empire Cancer Campaign and a grant towards the expenses of a director of research. It was not difficult to choose that director. Dr. Elizabeth Hurdon held all the necessary qualifications. She had been an associate in gynaecology at the Johns Hopkins Hospital, she had had a wide experience of team-work in the highest sense under the "Big Four" of the Johns Hopkins Hospital, she was a Fellow of the American Chirurgical Society, and had been a collaborator with Howard Kelly in the publication of two important textbooks. Moreover, she had a knowledge of foreign languages and American and foreign medical literature. The success that followed this choice which soon developed into the founding of the Marie Curie Hospital, would not have been possible had it not been for the enthusiasm of its director. She visited most of the continental and American clinics in which cancer was being treated by radium and x-ray therapy, and together with the Cancer Research Committee elaborated the technique to be followed. But it was especially due to Dr. Hurdon that such a difficult piece of team-work was made possible.

Her loyalty and unfailing good temper, her wide knowledge, her generous advice, and, above all, the scrupulous care insisted upon in the pre- and post-operative care of the patients—these were the factors that made what was a great experiment into a brilliant success. Two years ago she retired from the post of director, receiving from His Majesty the King the Order of Commander of the British Empire. She then devoted herself to the writing of a book on cancer of the uterus, giving the results and experiences of the Marie Curie Hospital, and it is hoped that this much-needed work may shortly be published.

JOHN GILLIES PRIESTLEY, M.C., D.M.

By the death of John Gillies Priestley, which occurred on February 9 at the age of 61 years, the School of Physiology at Oxford has suffered a loss which, at this critical time, it can ill afford. To many his friendship meant much. A man of great personal charm, generous to those in need, and always ready to lay aside his own work to help those who sought his advice or encouragement, he had for many years to face ill-health, and to the end he fought against this with characteristic courage. If he was critical of the work of others he was still more critical of himself, and to those who were his pupils he tried to impart something of that accuracy of observation and careful judgment which distinguished his own researches. With a clear perception of the relationship of physiology to medicine he was largely responsible for initiating a practical course of human physiology in the Honours Course at Oxford.

Priestley was educated at Eton and Christ Church, where he gained an open scholarship in 1898. Whilst reading physiology at Oxford he came under the influence of John Haldane, and the friendship thus begun had a profound influence on his future career. As soon as he had taken his degree he joined Haldane in the investigation which resulted in 1905 in the publication under their joint authorship of the well-known paper on "The Regulation of the Lung Ventilation," which has played so large a part in the development of physiological knowledge. He then completed his medical qualification at St. Bartholomew's, and it was just after this that he suffered a serious illness which was destined to leave him with permanently impaired health, a tragedy indeed to one who had served with distinction at Oxford and had a keen interest in

outdoor sport and big-game shooting. Within a year or two he was back in Oxford, and at once began a series of researches on the part played by the kidney in regulating the composition of the blood. Then the European war broke out. He at once volunteered for service, and, receiving his commission in the R.A.M.C. on September 1, 1914, he served in France and Belgium, gaining the Military Cross and being mentioned in dispatches in 1915. Later on in the war he was recalled to England, and there took part in a valuable investigation into the after-effects of war-gas poisoning. When peace came he returned to Oxford and was appointed Reader in Clinical Physiology. Receiving a scientific grant from the B.M.A. in 1920, he continued to work on various aspects of the physiology of respiration and on the kidney, and no one could have been more fitted than he to be associated with Haldane in preparing the new edition of Haldane's book, *Respiration*, a task to which he devoted an immense amount of care. He was joint author, too, of *Human Physiology, a Practical Course*, which has passed through two editions. Later on he was interested in certain problems of general metabolism and muscular exercise, and undertook a critical examination of methods for ascertaining the output of the human heart, his last paper on this subject being published barely two months before his death.

The Physiological Society owes to him the preparation of a subject index of the first sixty volumes of its journal, and for some years he edited *Physiological Abstracts*, in which he was able to employ his expert knowledge of the international decimal classification of scientific papers.

He leaves a widow and a son, Major Charles Priestley, R.A.

HAROLD SCURFIELD, M.D., C.M., D.P.H.

A familiar figure in the public health world of the first quarter of the century has passed away in the death at Letchworth on February 8 of Dr. Harold Scurfield, formerly medical officer of health for Sheffield.

Scurfield was born at Sunderland in 1863, and was educated at Birkenhead School, from which he went to the University of Edinburgh. He qualified M.B., C.M. in 1885, took the M.D. of Edinburgh four years later, and subsequently the D.P.H.Camb. After holding various appointments in Lancashire he returned to his native Sunderland at the age of 27, where he became medical officer to the Post Office and surgeon and agent to the Admiralty. This was followed in 1896 by his appointment as medical officer of health for Sunderland county borough and port. In 1904 he was appointed medical officer of health for the City of Sheffield, and there he remained until his retirement in 1921. It was an arduous post to fill, in the fifth largest town in England, with a population approaching half a million, and with much overcrowding, the legacy of the rapid development and prosperity of the steel industry which Sheffield had enjoyed and suffered in the nineteenth century. Many improvements were effected during Scurfield's time, and many more have been effected since, and the largely transformed Sheffield of to-day, with a death rate lower than most of the other industrial towns of Yorkshire, owes not a little to his seventeen years' work there. One problem which had always interested him was tuberculosis, especially from the standpoint of preventive measures and administrative control, and he wrote many papers on the subject. At the International Tuberculosis Congress at Rome in 1912 he was rapporteur on the subject of tuberculosis in the British Isles. He was the translator of Prof. E. Nocard's *Les Tuberculoses Animales*, and the author of the volume on *Infant and Child Welfare* in the English Public Health Series in 1919. He also published a number of lectures he had given in Sheffield in 1909 on the report of the Poor Law Commission. These were delivered from the chair of Public Health in Sheffield University, which he held together with his medical officership. From 1910 to 1913 he was examiner in preventive medicine and public health for the University of Oxford. In later years he was to be seen at almost every congress which had to do with sanitation, public health, tuberculosis, and infant welfare, where he reported for one of the medical journals, and occasionally made a brief but always practical contribution to the discussions. When the British Medical Association held its Annual Meeting at Sheffield in 1908 he was vice-president of the Section of Public Health and Forensic Medicine.

In his early days Scurfield was a rugby footballer and had a place in the Edinburgh University XV. Latterly he had lived in retirement at Folkestone. He had been twice married, and by his second wife had four sons and four daughters.

The death of Dr. A. G. HERON, a well-known and respected physician in the Dromara district, Co. Down, was announced on January 1. Dr. Heron was educated at the Royal Belfast Academical Institution, entering upon his medical course at the Queen's College, Belfast, in 1894 with the Lady Packenham Scholarship. He took the B.A. degree of the Royal University of Ireland, and graduated M.B. in 1901. He was a keen rugby player in his university days, was several times chosen for the Ulster side, and in 1901 played for Ireland. Immediately after he qualified he went out to South Africa, where he acted as a civil surgeon in a Field Force, and there he remained for a year before returning to Britain to take up an assistantship in London. Although he was offered a partnership he preferred, two years later, to go back to Ireland, where he established a practice in Dromara and was appointed dispensary doctor for the district. In 1908 Dr. Heron obtained his M.D., and continued his medical studies by taking post-graduate courses in both London and Belfast. In the last war he served in France with the R.A.M.C. in 1917–18.

Dr. HUGH G. WILSON died at Larne Harbour on January 13 after two months' illness. He graduated M.B., Ch.B. at the University of Glasgow in 1912, and with the outbreak of war joined the R.A.M.C., serving with the Royal Irish Rifles from 1914 to 1918. He did not take up general practice, but devoted his time to the sea, making many voyages as ship surgeon. Later he settled in Larne, and when war came in 1939 he volunteered for A.R.P. work, being particularly interested in the organization of the mobile post in his area. In his university days Dr. Wilson was well known as an Irish rugby international, being capped eighteen times. Among his interests in later years was welfare work for ex-Service men.

Dr. ROBERT ALEXANDER MORRIS, J.P., died suddenly at Harrogate on January 25, at the age of 68. From Morpeth Grammar School he went to study medicine at Newcastle-upon-Tyne, taking the English Conjoint diplomas and the M.B., B.S. degrees of Durham in 1894, and proceeding to the M.D. in 1909. At the University of Durham Medical School he won an entrance scholarship, the Gibb scholarship for pathology, and the Dickinson scholarship and gold medal. After serving as resident house-surgeon at the Royal Victoria Infirmary, Newcastle-upon-Tyne, he practised at Bedlington, and then about fifteen years ago went to Harrogate, where he entered into partnership. Dr. Morris was a Justice of the Peace for the County of Northumberland and much interested in golf and Freemasonry. He had been a member of the British Medical Association for forty-one years. In 1935 he recorded in detail jointly with Drs. Sinclair Miller and Thacker Neville in the *British Medical Journal* a case of agranulocytic angina.

Dr. WILLIAM ARTHUR REES, O.B.E., who died suddenly at Swanage on January 29, had been a distinguished student of the Middlesex Hospital, where he won an exhibition and the Broderip scholarship. He graduated M.B. of London University in 1903, took the F.R.C.S. in 1904 and the M.D. in 1906. He was casualty medical officer at the Middlesex Hospital and registrar and pathologist at the Bolingbroke Hospital, Wandsworth, and during the last war temporary Captain R.A.M.C. After settling at Swanage Dr. Rees became honorary medical officer to the local cottage hospital and surgeon to the Dorset Red Cross Children's Hospital. Ll. A. B. writes: As a partner of the late William Arthur Rees for the past twenty-nine years, I wish to pay tribute to one with whom I worked in perfect friendship all the time. He was a partner *par excellence*, a loyal comrade, and a tower of strength to those who had the pleasure of working with him. Possessed

of great clinical acumen. he never forced his [illegible] professional ability on anyone and was always ready to [illegible] any criticism of his cases, or his treatment of [illegible] the greatest respect. I have no doubt that the [illegible] through in France in 1915–18 and the overwork [illegible] three months caused his sudden collapse from [illegible] bosis at the age of 62. His patients were devoted [illegible] he always gave of his best to them.

Dr. CHARLES WILLIAM CHAPMAN died at [illegible] Hants, on January 31 in his ninety-eighth [illegible] trained at Guy's, and qualified L.S.A. and M.R.C.S. [illegible] L.R.C.P. in 1868, M.R.C.P. and M.D Durham [illegible] counted among his personal friends Lord Lister, Sir [illegible] Wilks, Sir Charters Symonds, and Sir James Cr[illegible] In the early days of his career he was attached [illegible] request, to a special unit to fight a cholera outbreak [illegible] After some years of general practice he specialized [illegible] logy, and became attached to the National Hospital [illegible] Diseases of the Heart, of which hospital he was [illegible] years senior physician. One of Dr. Chapman's [illegible] possessions (writes J. E. R.) was a testimonial subscribed [illegible] mostly in coppers—by his out-patients at that hospital [illegible] published three textbooks, the last, *The Heart and Its [illegible]* being produced at the request of E. and S. Livingstone when he was 83 years of age. Some of his old patients had such faith in him that they insisted on his examining them occasionally long after he retired. I know that two patients travelled from London last year for this purpose. He could thus claim to have practised medicine for seventy-four years. He was active in mind and body to the last, and only a few days before his death he dressed and came downstairs as he did every day. He read the *B.M.J.* and the *Lancet* every week to the end, and he was naïvely proud of *his soft arteries*—and they certainly were wonderfully soft for a man of his age. He was a lovable character and a man who had disciplined himself strictly and practised his profession all his life with only the interest of his patients at heart. He is survived by a widow, two sons, and two daughters. One of his sons, Dr. David Chapman, is in practice at Bridlington, Yorks.

By the death of GEORGE HENRY MASSON O.B.E., M.D., F.R.C.P.Ed., the West Indies has been robbed of one of its most brilliant sons. He was a man of outstanding intellectual attainments. In addition to his many academical qualifications he was a linguist of no mean order. He received the O.B.E. in June, 1936. He had been a member of the British Medical Association for sixteen years, and in 1933–4 was president of the Trinidad and Tobago Branch. A student under Sir Robert Philip (writes E. C.), Dr. Masson built up a tuberculosis dispensary scheme in Port of Spain at a time when the majority of cities in Great Britain had barely begun to consider the project. Yet this great work formed only a part of his contribution to public health in the West Indies. But it is not by these achievements alone that he will be remembered. He had one of those rare personalities that inspired a deep sense of affection, as well as respect, in his colleagues. Despite his distinguished record he was modest and unassuming, always prepared to listen to other men's problems and to give advice and help. To those of us, West Indians and Europeans alike, who enjoyed his friendship his death has been a heavy blow.

Nearly 700 applications from fever or tuberculosis nurses have been received in answer to the recent appeal of the Minister of Health. Particulars of nearly 300 of these—250 fever nurses and fifty tuberculosis nurses—have been sent to the medical officer of health of districts known to be in need of their services. Of the remainder, forty applicants are unwilling to work outside their own district, and are not at present needed there. About 200 have proved unsuitable: and the other 150 applications are being sifted rapidly. Still more fever and tuberculosis nurses are wanted, particularly those who are willing to go wherever they are needed. Applications, giving name, address, age, qualifications, and experience of fever or tuberculosis nursing, with particulars and date of certificate, etc., and present employment, if any, should be addressed to the Minister of Health, Whitehall, S.W.1, and the envelopes marked "Fever Nursing."

Medical Notes in Parliament

National Wheatmeal Flour

Mr. LLOYD GEORGE told Sir Ernest Graham-Little on [illegible] 12 that the term "wholemeal" was loosely applied [illegible] made from flour containing between 80% and 100% [illegible] meal berry. Lord Woolton was arranging that a flour, [illegible] as national wheatmeal, milled to standards laid [illegible] by his scientific and technical advisers, would shortly [illegible] available by all controlled flour millers at the same [illegible] as national straight-run flour. It was not Lord Woolton's [illegible] to withhold subsidy from bread made from other [illegible] flours providing the conditions of subsidy were [illegible]

Food Rationing

In the House of Lords on February 18 a debate took place [illegible] provision of essential foods for the civilian population [illegible] the defence Forces. Viscount DAWSON urged that there [illegible] be a nearer equation between the food granted to the [illegible] and to the civilian population than was the case in [illegible] war. There was, he said, no evidence of resulting [illegible] from rationing, though there was a reduction in [illegible] in some cases. He urged that there should be a [illegible] importation of powdered whole milk and powdered [illegible] milk, as well as vegetable protein in the form of powder. He congratulated the Minister on the projected sale of the standard wholemeal loaf and appealed to the people of the [illegible] to realize what they were losing by not gradually [illegible] themselves to eat wholemeal bread. Lord WOOLTON, Minister of Food, replied.

Treasury Grants to Universities

On February 18 Mr. PICKTHORN asked the Chancellor of the Exchequer if he could make a statement on the Treasury grant-in-aid to the universities and colleges during the coming financial year. Sir KINGSLEY WOOD said that the House would recall that, in view of the vital part played by the universities in the life of the community, the importance of maintaining so far as possible the standards of university education, and the essential contribution which the universities were making in a variety of ways towards the national effort, it was decided to maintain the provision for the current year at the same level as that in 1939—namely, £2,149,000. These considerations had lost none of their force, and in spite of the increasing strain on the national finances, the Government, after considering a report from the University Grants Committee, had reached the conclusion that if the universities were to continue their present contribution to the national effort the provision for 1941 must be maintained at the existing level. They earnestly hoped that local authorities would take similar action.

Medical Attendance on Home Guard.—On February 18 Captain MARGESSON said that a private medical practitioner giving free attendance to a Home Guard casualty or casualties, incurred in action with the enemy, would be entitled to call on such Army medical services as were operating in the area to provide any necessary assistance.

Superannuation and Military Service.—The Service Departments are reviewing the question of the superannuation benefits of officers and nurses employed in voluntary hospitals and serving in units of His Majesty's Forces.

Notes in Brief

Proposals have been received by the Ministry of Health from a group of nutrition experts attached to the California Institute of Technology to supply to this country in syrup, powder, and tablet form certain vitamins and other ingredients which, it is claimed, have been proved to bring about improvements in health. They are under consideration with other Departments concerned.

The Ministry of Home Security has issued about 1,250,000 anti-gas helmets for babies, each helmet accompanied by the printed leaflet of instructions.

Out of 53,467 children inoculated in Liverpool during the years 1925 to 1939 inclusive the number of deaths from diphtheria was ten. Statistics of inoculations during 1940 are not yet available, but it is known there were no further deaths among the inoculated children.

Medical News

The annual meeting of the Central Council for District Nursing in London will be held at the County Hall, Westminster Bridge, S.E., at 2 p.m., on Thursday, February 27.

The University Extension and Tutorial Classes Council in co-operation with the Central Association for Mental Welfare proposes, if there is sufficient demand from general practitioners, to hold this year as usual a course of lectures on and clinical instruction in mental deficiency. The course, which will probably be held at Oxford, will include: (1) Lectures on the nature of mental deficiency, its pathology, causation, and classification (Dr. A. F. Tredgold), administrative procedure under the Mental Deficiency Acts, the work of the school medical officer in relation to defectives, and the psychology of defectives. (2) Clinical demonstrations with, it is hoped, a visit to a certified institution. (3) Mental tests of individual children. The registration fee will be 10s. 6d. and the fee for the course £5 15s. 6d. A suggested date is March 24 to April 4, but the course can only be held if the number of applicants justifies it. All who intend taking the course, therefore, should make application at once to the honorary secretary, Miss Evelyn Fox, c/o University Extension Department, University of London, 24, Buckingham Palace Road, S.W.1.

In view of the confusion which has arisen, the Minister of Health has approved the following names as the "proper names" for the purposes of Part I (A) of the Second Schedule of the Therapeutic Substances Regulations, 1931: (1) Anti-typhoid-paratyphoid A, B, and C vaccine. (2) Anti-typhoid-paratyphoid A and B and cholera vaccine. No abbreviation should be made in respect of the latter name.

Dr. A. J. Ireland, now serving with a commission in the R.A.M.C., and formerly in practice at Tunstall, Staffs, was bound over for two years at Chester Assizes on February 17 by Mr. Justice Croom-Johnson. The charge, to which he pleaded guilty, was that of giving false information concerning a birth and making a false statement that a birth had taken place. The trial followed a case at the last Assizes in November, in which his wife Lizzie, also known as Lady Haldon, was sentenced to three years' penal servitude on charges of conspiring and making a false claim about the baby's birth and two charges of bigamy. His commanding officer described Dr. Ireland as an exceptionally eager professional man and a most capable officer, and it would be a great loss to the Army if it were deprived of his services. The judge, passing sentence, said: "I think the public interest will best be served by allowing you to go back and continue your duty. I had in mind to sentence you to a term of imprisonment, but I have been struck by your military record."

According to the *Jewish Chronicle*, typhus is now raging in a forced labour camp recently established by the Nazis for 1,800 homeless Jews at Miechow, near Cracow. The disease is also causing havoc in Dzialoszce in the same district, where many Jews are dying every day from lack of medical aid.

A severe outbreak of plague has recently occurred in Manchuria.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

In this week's issue we print two tables for the third and fourth weeks of January respectively, and so bring epidemiological information more up to date. The outstanding feature of January has been the decline of the measles epidemic and the almost simultaneous rise in the incidence of whooping-cough. Hardly less important is the fall in the notifications of diphtheria, which, though not attended by a like fall in mortality, augurs well for the immediate future. How far recent immunization campaigns are responsible cannot yet be determined with certainty. Scarlet fever continues to increase but fatality remains low. Cerebrospinal fever and influenza deserve more detailed notice.

Cerebrospinal Fever

Notifications of cerebrospinal fever continue to increase, and it is much more prevalent than at the corresponding period last year; but the rate of increase is less steep. In the third week of January the number of administrative areas involved rose from forty-four to forty-six, and in the last week to forty-seven, appearing in five and disappearing from four. The disease was even more widespread in Wales, where eleven out of thirteen areas in the Principality were involved in the third week, but the disease appeared in three—Caernarvon, Cardigan, and Radnor—in the last week. The figures for the two weeks in chronological order for the areas chiefly affected are: Lancaster 59, 58; London 24, 22; West Riding of Yorks 18, 18; Gloucester 14, 9; Glamorgan 14, 19; Warwick 11, 13; Durham 9, 5; Middlesex 9, 2; Stafford 9, 9; Southampton 8, 7; Surrey 8, 11; Worcester 8, 4; Chester 7, 9; Kent 7, 11; Bedford 6, 2; Somerset 6, 3; Monmouth 6, 6. Notifications for the week ending February 8 numbered 345.

Influenza for Week Ending February 8

The return of deaths for the 126 great towns, 261, breaks the sequence of repetitions of the 1929 experience; then 179 was followed by 321. The ratio of 261 and 176 is almost the same as the ratio of 176 to 120, so it is very unlikely that a maximum has yet been reached, but it becomes increasingly improbable that the maximum will be of the order of magnitude of that of 1929 and not unduly optimistic to think that it will not exceed that of 1940. The age distribution of deaths is quite normal—52% over 65 and 10% under 25; the latter proportion is greater than last week, when it was abnormally low; 10% is about the usual figure. The detailed figures for London suggest that the maximum of mortality is near, that it may well be in the now current week, and that the maximum of admissions of cases of influenza, pneumonia, and bronchitis to hospital is already passed. The proportion of total deaths coming from the South-Eastern Area (including London) is still over 50%, and it remains to be seen whether mortality in the North will increase at a faster rate; but the general impression conveyed by this return is favourable.

Total of Influenza Deaths and Deaths in Age Groups in 126 Great Towns for Week Ending February 8

All Ages	A Under 1 year	B 1-5	C 5-15	D 15-25	E 25-35	F 35-45	G 45-55	H 55-65	I 65-75	J 75 and over

Trichiniasis

In view of the recent outbreak of trichiniasis at Wolverhampton, and the occurrence of cases elsewhere, the practitioner should regard this disease, hitherto a rarity in this country, as among the febrile conditions that he may be called upon to diagnose. Prompt diagnosis is important, not, unfortunately, because there is any specific treatment, but because it is an urgent matter to trace all infected pig carcases, since the consumption of inadequately cooked pig muscle is the only way in which the disease is conveyed to man. A practitioner should always inform the Medical Officer of Health of his area immediately he encounters a case, so that the necessary inquiries may be made and the infected carcase traced. The outstanding symptoms are fever, muscular pains, and headache, often accompanied by swelling of the face, and particularly of the eyelids. During the earliest stages of the disease, when the worm embryos are maturing in the small intestine, there may or may not be gastro-intestinal disturbance and abdominal pains. Sometimes there are symptoms referable to involvement of the central nervous system. At the present season such cases may be, and have been, diagnosed as influenza. It is fortunate that a differential blood count will almost always settle any doubts, since a well-marked eosinophilia is present from an early stage of the disease.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY MARCH 1 1941

DEPRESSIVE STATES IN WAR

BY

DESMOND CURRAN, M.B., F.R.C.P., D.P.M.

Temporary Surgeon Captain, R.N.V.R.; Consultant in Psychological Medicine to the Royal Navy; Psychiatrist to St. George's Hospital, London

AND

W. P. MALLINSON, B.M., M.R.C.P.

Temporary Surgeon Lieutenant-Commander, R.N.V.R., Neuro-psychiatric Specialist; late Assistant Medical Officer at the Maudsley Hospital

It is proposed to draw attention to the frequency of depressive states in war and to record the results obtained in an analysis of 88 consecutive cases admitted to the neuro-psychiatric unit of a Royal Naval auxiliary hospital.

The literature on war psychiatry might suggest (1) that the incidence of psychiatric disorders had greatly increased; (2) that this was almost entirely due to a greater incidence of "neurosis" of either anxiety or hysterical type; and (3) that the incidence of depressive illness was comparatively small, scarcely rising above that in the civilian population. Thus in a recently published book, *The Neuroses in War* (1940), which includes a survey of the literature, only a few passing references are made to depressive reactions; their differential diagnosis is not discussed, and even the term "depression" finds no place in the index.

Lewis (1934) has put forward the following definition of depressive illness: "A condition in which the clinical picture is dominated by an unpleasant affect, not transitory, without evidence of schizophrenic disorder (other than slight and subordinate) or organic disorder of the brain, and in which, moreover, the affective change appears primary, and not secondary to other symptoms of ill-health." If this definition is accepted a substantial proportion of psychiatric cases occurring in the Royal Navy must be classed as depressive states. Thus "depression" and "hysteria" as primary diagnoses have during recent months been made with almost exactly the same frequency (13%) in the cases (including the neurological) admitted to this particular neuro-psychiatric unit, whilst in the first part of 1940 the diagnosis of depression was three times as common as that of hysteria (Curran and Mallinson, 1940). However cases of depression may be classified the scarcity of reference to them in the literature is difficult to understand.

It is possible that reluctance to make the diagnosis of depression has arisen from the implication of "psychosis," which to so many suggests an illness of certifiable intensity. Experience in the Navy has confirmed the often-expressed opinion that the incidence of certifiable insanity is not greatly increased as a result of war stress. But it is unusual for psychiatrists to equate "psychosis" with certifiable insanity, although in view of the confusion which has arisen about this term there is much to be said for doing so. Probably most psychiatrists would still class as psychoses certain illnesses which never reached such intensity, and some of them would maintain that there was an essential qualitative as well as quantitative difference between psychosis and neurosis, which it was important to recognize because of the prognostic and therapeutic implications (Ross, 1923; Yellowlees, 1932). Reasons have been given elsewhere (Curran, 1937) why this last view should be regarded as false for cases met with in civilian practice, and it equally finds no confirmation in the naval psychiatric cases arising in this war, which seem quite clearly to form a continuous series.

The cases considered here were classed as depressive states because in all of them the depressive aspect predominated over such anxiety or hysterical features as were present. They ranged from cases of certifiable intensity to quite mild reactions showing excellent insight, a high degree of reactivity to their environment, and no evidence of such "endogenous" symptoms as retardation and self-reproach. Difficulties in making a satisfactory classification of depressive states are inherent in the nature of the material. For here again it is not a question of a sharp distinction between an "endogenous" or mainly constitutional illness and one which is "exogenous" or "purely psychogenic"—between a "manic-depressive" and a "reactive" or "neurotic" depression—but of varying proportions of constitutional predisposition and external stress. The following classification is not, therefore, intended to do more than roughly assess which of these two factors—constitutional predisposition and external stress—seemed to be the more important in the individual case:

1. "Endogenous depressions," which might or might not have been precipitated by external stress, mainly characterized by certain typical symptoms such as retardation, ideas of reference and self-reproach, and a "depressive content."

2. "Reactive depressions," mainly characterized by the dependence of the illness upon traumatic experiences which gave rise to a "topical content," but not showing the typical "endogenous" symptoms mentioned above with the same frequency or intensity.

In making the final decision each case was considered as a whole. Many cases fitted into the above classification well enough; a large number did not. By a strange chance each group was found to contain 44 cases, and of the total 33 were "regulars," 48 reservists, and 7 "hostilities only" recruits.

Method of Classification

It is now proposed to see what emerges from a comparison of the two groups and from an analysis of the findings in this series of depressive states as a whole. In order to do this the material has been summarized in

tabular form (Table I). Considerable distortion must inevitably result from the severance of particular aspects from their total and individual setting, but no other course seemed possible, for clearly we could not give full case records.

TABLE I

	Classification		Returned to Duty	Social Recovery	Reduction of Social Capacity
	Endogenous	Reactive			
No. of cases	44	44	25	40	23 (including 1 suicide)
History					
Average age	34	37.5	32	38	37
Family history of mental disorder	17	12	8	14	7
School record below Standard V	11	7	2	10	6
Bad work record	9	6	5	9	1
Unsatisfactory personality	7	8	5	9	1
History of a previous attack	16	9	5	18	2
Special war stress	8	19	6	14	7

Physical factors	5	18	4	12	7
Symptoms					
Retardation	29	15	11	20	13
Ideas of reference	18	6	6	11	7
Self-reproach	27	9	8	16	12
Depersonalization	9	1	1	6	3
Somatic preoccupations	32	22	13	26	15
"Content" Depressive	37	13	14	23	13
"Content" Topical	4	27	10	13	8
"Content" Mixed	3	4	1	4	2
Anxiety	25	36	14	32	15
Reactivity	14	20	13	19	2
Hysterical prolongation	15	20	7	23	5

Past History

Family History.—Recorded only when a near relation (parent, aunt, uncle, or sibling) had been in a mental hospital, or when more than one such relation had shown unmistakable evidence of psychiatric disorder (e.g., "shell shock," or obvious psychopathy as shown by chronic alcoholism or a bad work record).

Work Record.—Recorded only when this appeared to be definitely unsatisfactory from such objective evidence as frequent changes of job.

Personality.—Recorded only when such features as well-marked hysterical or schizoid "psychopathy" or long-standing anxiety of pathological intensity were present.

Previous Attacks.—Only one patient had a previous attack of sufficient severity to necessitate mental hospital care, and in only four cases was there a history of more than one previous attack.

Special War Stress.—Recorded only when there had been a direct experience of enemy action such as torpedoing, mining, air-bombing, or immersion. The often prolonged and severe hardship and danger to which the majority of these men had been exposed has not been recorded.

Domestic Misfortunes.—All of these men had, of course, been exposed to the complications or disruption of their life entailed by active service. Details of the only factors recorded are as follows: in the endogenous group, 2 broken engagements and 6 deaths (3 mothers, 1 wife, 1 fiancée, 1 child); in the reactive group, 2 deaths (1 wife and 1 child). Justified concern over the health or behaviour of wives, the evacuation of families from bombed areas, and financial difficulties make up the remainder of the factors recorded.

Symptoms

Depression.—In all these cases the clinical picture was persistently dominated by a depressive affect as judged by general behaviour as well as by what the patients actually said.

Retardation.—Recorded only when definite and *objective* evidence of "slowing-up" was present; for complaints of difficulty in concentration and in making decisions were almost universal.

Ideas of Reference.—Recorded only when they went beyond what could reasonably be interpreted as heightened self-consciousness. They were seldom very persistent or intense, and it is probable that the expression of such ideas was often checked by the natural feeling of a disciplined man that such "silliness" should not be encouraged.

Self-reproach.—Care was taken not to record such apparent expressions of self-reproach as "I've let the side down once, and I don't feel I could go back, because I might let it down again," if such statements seemed to depend upon hysterical ("escapist") motives and were more in the nature of rationalizations than genuine beliefs.

Depersonalization.—Recorded only when persistent. It was certainly more prevalent than the figures show; for its expression requires considerable powers of accurate introspection and a lucidity of exposition which many ratings do not possess. Thus it was recorded in 4 out of 13 officer patients, but in only 4 out of 75 ratings.

Somatic Preoccupations.—Recorded only when more than a transient topic of concern.

TABLE II.—*Somatic Preoccupations*

	Endogenous Cases	Reactive Cases
Headache and head sensations	12	10
Gastric complaints	7	4
Visual complaints	5	3
Bowel preoccupations	1	3
Fear of syphilis	2	1
Fear of cancer	2	0
Genital preoccupations	3	1

The remaining somatic complaints were of "weakness," pains in the limbs, and discomfort in the throat and chest. In view of the prevalence of anxiety it is a striking fact that only one patient (an "endogenous" case) complained of cardiac symptoms.

Anxiety.—Recorded only when *objective* signs were definite and pronounced.

"*Reactivity.*"—By this was meant the response to environmental influences such as psychotherapy or occupational therapy, or the daily events in the hospital; not the degree in which the illness was consequent upon external stress.

Content.—An artificial distinction was made between those who were mainly preoccupied with traumatic experiences responsible for their breakdown and those who showed depressive preoccupations of a more generalized type. These were called "topical" and "depressive" contents, and were considered to be characteristic of the reactive and endogenous groups respectively.

"*Hysterical Prolongation.*"—Few patients are eager to return to conditions of danger and discomfort, and consequently the depressive illnesses were often complicated or prolonged by the operation of hysterical (or "escape") mechanisms.

Aetiology

The aetiological factors may be grouped under four headings: (1) constitutional, (2) physical, (3) environmental, and (4) factors related to the personality. The last group may be regarded as the end-results of the previous interaction of constitutional and environmental influences.

1. *Constitutional.*—The importance of a constitutional predisposition is shown by the fact that 29 of the cases (17 endogenous and 12 reactive) gave a family history of mental trouble, while 25 (16 endogenous and 9 reactive) gave a history of previous attacks. A family history of mental illness necessitating mental hospital care was more common amongst the endogenous group (7 cases, as compared with 3 cases in the reactive group).

2. *Physical.*—It will be seen that physical disorders were found in 23 of the patients. It is probable that all of these (except in the cases showing symptomless urinary tuberculosis and albuminuria) had some influence in the causation and prognosis of the depressive reactions. The significance, of course, varied greatly from case to case; in a few (e.g., the cases of concussion and influenza) the physical disorder was a direct precipitating cause of the breakdown. Prognostically, arteriosclerosis and head injury were the most unfavourable of

the physical factors met with, while all three of the cases which were associated with influenza made a complete recovery and returned to duty (Table III).

TABLE III

Physical Factors	Classification		Returned to Duty		
	Endogenous	Reactive			
Influenza	–	3	3	–	3
Arteriosclerosis	1	6	–	–	–
Head injury	–	4	1	–	1
Sea-sickness	1	2	–	1	1
Syphilis (not neuro-)	–	1	–	1	1
Duodenal ulcer	1	–	–	–	–
Alcoholism	1	1	–	–	–
Urinary tuberculosis	–	1	–	1	1
Albuminuria	–	–	–	–	–
Fractured scapula	–	–	–	–	–
Totals	5	18	4	3	7

3. *Environmental.*—The main environmental [illegible] which these men had been subjected were [illegible] home life, representing in the case of many [illegible] removal of a recently earned reward which has been deferred although keenly anticipated, during their careers in the Services; (*b*) bereavement or other domestic misfortunes which [illegible] hard enough to bear in peacetime, were sometimes found to be intolerable under the conditions of separation and limited [illegible] prevailing in wartime; and (*c*) prolonged exposure to danger and discomfort; and in 27 cases (8 endogenous and 19 reactive) personal experience of a naval disaster, such as mining, torpedoing, and air-bombing, often involving the deaths of messmates and friends.

4. *Personality.*—It will be seen (Table I) that in only 15 cases (7 endogenous and 8 reactive) was the personality considered to be unsatisfactory or "psychopathic." Further information about the personalities of these patients is given in Table IV.

TABLE IV

Recorded in Table I

Endogenous Group	Reactive Group
3 hysterical psychopaths 2 schizoid psychopaths (one of them described by a colleague as "a schizoid sour grape") 1 reformed alcoholic 1 chronic hypochondriac	7 hysterical psychopaths 1 constitutional inferior

Not Recorded in Table I

10 excellent personalities 6 conscientious personalities (3 of them also "dull") 12 simple or "dull" personalities (3 of them also conscientious) 6 of a sensitive worrying type	11 excellent personalities 5 conscientious personalities 11 simple or "dull" personalities (5 of them also conscientious) 10 of a sensitive worrying type (5 of them also conscientious)

The majority were worthy, strikingly conscientious, self-disciplined men of a rather dull, unimaginative, plodding type who had previously stood up well to their responsibilities and the demands made upon them by their lives. But they were not men who were highly endowed with initiative and enterprise, and those very qualities which had made them trustworthy workers of a routine type made it difficult for them to adapt themselves to the altered conditions entailed by active service in wartime, away from their homes and the set ways which meant much to them. Moreover, in 18 cases (11 endogenous and 7 reactive) a significant degree of mental backwardness tended to increase their difficulty in adaptation. Finally, the average age of the group was notably high, and, presumably owing to their hard life, ratings are often old for their years.

In Table V the age incidence of these depressive cases is contrasted with that in a parallel series of 63 hysterics.

TABLE V

	No. of Cases	Under 25	25–35	35–45	Over 45	Total Under 35	Total Over 35	Average Age
Depression	88	12.5	25.0	46.5	16.0	37.5	62.5	36
Hysteria ..	63	43.0	27.0	25.5	1.5	70.0	30.0	29

The difference in the categories, as well as in the age incidence, is also informative, for only 7 of the depressive cases were "hostilities only" recruits, compared with 20 "hostilities only" recruits in the hysterical series. Again, 13 of the depressive cases were officers, and only 1 of the hysterics. In summary it seems reasonable to conclude that the depressive cases were for the most part excellent men, who finally broke down not through any deficiency in morale but largely owing to certain deficiencies in adaptability, due to a number of causes—their age, their temperament, and, in quite a high proportion, incipient backwardness or arteriosclerosis.

Results

The results obtained are given in Table VI. It will be seen that approximately 28 % returned to duty and that only 2 % showed on discharge any significant reduction in their previous social capacity, not more than five cases needing further hospital care. When it is considered that the duration of stay hardly ever exceeded three months and that most of the cases were in hospital for a shorter period, these results are very good. Nor can this be wholly attributed to mildness, for the majority showed a reaction which at some time was of considerable severity. The "reactivity" of these cases was therefore a very striking phenomenon.

TABLE VI

	Endogenous	Reactive	Average Duration of Illness (excluding 2 Patients with Illness of 7 Years)
Duty	12	13	4.1 months
Recovery with little or no reduction of social capacity	19	21	6.9 "
Improvement with some reduction of social capacity ..	7	10	6.7 "
Certified	4	0	
Voluntary patient	1	0	
Suicide	1	0	

Prognosis

The aetiological considerations mentioned above may help to explain the prognostic findings. In attempting to assess prognosis each case must of course be studied individually: the remarks which follow can only be regarded as broad generalizations.

The patients who returned to duty tended to show (Table I) those attributes which are associated with adaptability, such as relative youth, intelligence, and, above all, a plastic and resilient temperament. (This last attribute does not lend itself to a tabular record and hence has not been shown.) Thus it is not merely a coincidence that the proportion of officer patients who returned to duty was high (8 out of 13 cases). Indications of stability, such as a steady work record and "conscientious character," had some prognostic value, but were too apt to be combined with that rigidity and deficiency in adaptability already described. Turning to the illness itself, a duration of less than six months (Table VI) and symptoms of relatively mild intensity (especially if following some physical illness such as influenza) were favourable signs, but the most valuable of all seemed to be the degree of rapid "reactivity" that was shown.

Conversely, few returned to duty who had a poor school record or an illness lasting more than six months, especially if of a severe character. It will also be observed that a large number of those who, although unable to return to duty, made a good social recovery showed symptoms of hysterical prolongation; the early appearance of such symptoms makes an ultimate return to duty less likely. They often diminished or disappeared when the man knew he would be invalided.

The family history, special war stress, and domestic misfortune seemed to have less influence upon the prognosis than might have been expected. Nor did the presence of somatic preoccupations appear to make much difference, unless of a gross depressive type (e.g., "testes rotting") or associated with other symptoms indicating an illness of severity.

In the tabular records few differences can be seen between those cases which made a good social recovery and those which did not, with the striking exception of the lack of "reactivity" shown by the latter group. In dealing with war cases, which typically respond so rapidly, persistent unresponsiveness to environmental influences should therefore lead to prognostic reserve. It is sometimes possible, however, from a more detailed knowledge of the individual case, to suspect the reasons for an unsatisfactory social outcome. Thus some active service ratings (or "regulars") find themselves in a psychological impasse: they cannot face a return to duty, while invaliding leads to the termination of their careers. Again, it is embarrassing for a proud man to be invalided from the Service if he has no symptoms to show for it when he goes home. Finally, prolonged illness may occur, just as in peacetime (especially when arteriosclerosis is present).

Treatment

The same general principles must be applied to the treatment of these cases as are employed in all depressive states. They need not be recapitulated: an excellent account will be found in Diethelm's book (1936). Brief mention will only be made here of two aspects.

1. *Continuous Narcosis.*—The onset in these cases had usually been insidious. This is not surprising in view of the type of personality which has been found to be characteristic, and which is perhaps one of the conditions of their development. For individuals lacking the same conscientiousness or of a less robust temperament tend either to succumb to affective reactions at an earlier stage, before the more definite symptoms of depression become manifest, or escape by the development of hysterical illnesses before affective symptoms become manifest at all. Only one patient (the captain of a ship which was sunk by enemy action, not included in this series) has so far come under observation who, previously free from symptoms, developed a profound self-reproachful depression almost overnight after the catastrophe. It can therefore scarcely be expected that continuous narcosis should have the same value as in certain acute reactions of recent origin, like those described by Sargant and Slater (1940) in soldiers after Dunkirk. More restricted claims must be made for its value in depressive states and all results be reviewed in the light of the fact that these cases do very well without it. It would, however, be foolish to deny its value for more recent cases with much anxiety. The same arguments apply to the various forms of "shock therapy," which are further complicated by the possibility of fractures and dementia (Tooth and Blackburn, 1939).

2. *Psychological Treatment.*—The two main ways in which these cases differ from those met with in civilian practice are: (*a*) their "reactivity," and (*b*) the strong incentive that is present to hold back from complete recovery, which with few exceptions means a return to those conditions of stress responsible for the breakdown; for it is unusual to encounter a patient whose illness is totally unconnected, either directly or indirectly, with war service.

The first point—the reactivity—provides ample scope for psychological treatment, meaning by this both psychotherapy and individual psychological management within the framework of a regime of "occupational therapy" organized on the lines recently so well described by Cameron (1940). Skill is required in planning the patient's day according to his needs and capacity, and attention to apparently minor points, such as what patients should be in neighbouring beds, can make an important contribution. Mapother (1936), speaking of the acute anxiety states in the last war, has said that, without glorification as heroes, such patients needed and deserved all the sympathy and reassurance that could be given to them. The same holds true in equal measure for these states of depression. Perhaps the essence of psychotherapy in all affective reactions is to induce the patient to accept and to interpret his symptoms as evidence of illness entailing both restrictions and responsibilities, and those who suppose that the psychotherapy of depressions can be summarized in the formula of "*simple reassurance*" *make a profound mistake.*

The second point—namely, the danger of hysterical developments and prolongations—makes treatment even more difficult. These developments are natural enough in a man who has been severely ill, has rightly been reassured that he has been ill, has interpreted this as in some sense a moral absolution, and knows very well that a full recovery will mean a return to conditions of danger and stress. It is difficult, but most important, to try to judge when a psychobiological reaction of depressive type is being replaced by hysterical manifestations, and to reinforce sympathy with the firmness that is then called for. The dangers of retention in hospital must therefore be balanced against those of a premature discharge, but it is perhaps better to risk the relapse which may follow too rapid a return to duty, or to civilian life after invaliding, than the invalidism that may follow prolonged hospitalization. Nothing can be worse for some patients than uncertainty as to whether they will be invalided or not, and it is well to make as rapid a decision as possible.

Discussion and Conclusions

The facts put forward do not reveal any fundamental and clear-cut distinction between the endogenous and reactive groups, and had it been possible to demonstrate the cases, or even to give full case records, it could have been shown more convincingly that these depressive states formed a continuous series. The point is of some importance, for it is still often supposed that the question, "Is this case of depression of a psychotic or neurotic type?" necessarily permits of a categorical answer with important and definite prognostic and therapeutic implications (the "psychotic" depression being essentially a constitutionally determined reaction which runs its predestined course to ultimate recovery unaffected by any environmental influences, including psychotherapy; the "neurotic" depression, on the other hand, being essentially psychogenic and unlikely to recover without psychotherapeutic intervention). This is not so. Certain cases at each end of the endogenous–exogenous scale do more or less fulfil these criteria; such cases, however, are not separated by a sharp borderline but by a wide borderland. In brief, it is held that the classification adopted possesses meaning only as indicating towards which end of a continuous series (the extreme ends of which certainly differ widely) a given case belongs.

Similarly, there is an indeterminate zone where the question whether a given case should be classed as a depressive state with anxiety features or an anxiety state with depressive features is merely a matter of taste. Such mixed reactions shade off into "pure" anxiety states without any obvious features of depression at all.

A distinction which is justified on clinical and therapeutic grounds can, however, be made between "affective disorders," comprising cases in which either the mental and physical symptoms of anxiety or depression is the main feature, and hysterical reactions, in which "mental and physical symptoms not of organic origin are produced and maintained by motives, never fully conscious, directed at some real or fancied gain to be derived from these symptoms." (M.R.C. Report of Committee on Head Injuries—private information, unpublished.) The symptoms in the affective group are reactions of the whole organism in a way in which hysterical reactions are not. Thus physical symptoms the involuntary accompaniments of emotional disturbance, such as loss of weight and tachycardia, are to

be found. Some of these symptoms may be *biologically* purposive, but they are of a type which cannot be imitated voluntarily, have acquired a certain autonomy of their own which cannot be abruptly terminated by changes in the environment, and, as some might say, are outside the patient's control.

To suppose that all affective reactions (i.e. states of anxiety and depression) are of an "escape" type and *personally* purposive would be both to overvalue psychogenesis and to confuse it with hysteria. It is of course true that the two types of reaction—affective and hysterical—may coexist: the readiness with which a given patient will succumb to or will utilize in a hysterical way the symptoms of an affective disorder will vary. Certainly many patients do so; or are not able or willing to part with an affective reaction—especially the visceral components, which in themselves are not more severe than those experienced by other men who do not succumb. These are, no doubt, the causes of the incapacity produced by many so-called "organ neuroses," such as certain of the "functional dyspepsias" so common in the Services.

On the whole, therefore, it would seem more important to try to determine the presence and assess the intensity of genuine affective symptoms and to contrast this with the presence or absence of hysterical features rather than to contrast neurosis and psychosis. For the treatment of a predominantly affective reaction does differ fundamentally from that of hysteria, as does the type of personality that tends to be affected.

Broadly speaking, it may be said that the better type of individual, with a high sense of duty and morale, if he develops an illness as a result of war stress, will tend to develop an affective reaction. It is significant that many of these men did not report sick but were sent sick. The severity of the total psychobiological reaction to a given stress is presumably dependent mainly upon the constitutional predisposition, and severe depressive illness will only occur in the predisposed. On the other hand, men with a less strict sense of duty and lower morale tend to escape by the development of "pure" hysterical reactions or succumb to "affective" symptoms of relatively minor intensity. Consequently, assessment of the relative proportions of affective and hysterical features is of great importance in determining how much firmness should be shown, the possibility of a good response to semi-disciplinary measures, and whether a man should be kept at duty or not.

The group of cases that have been studied lie towards the depressive end of the scale of affective disorders. The type of personality in which these depressive reactions commonly arise and the constitutional, environmental, and physical factors which contributed to their development have been described. It has been noted that the majority of the patients, although showing symptoms of a constitutional or "endogenous" type, responded rapidly to environmental influences in hospital. This reactivity, although valuable from the point of view of therapy and a rapid recovery by civilian standards, increases the likelihood of relapse on return to active service. It does, however, serve to belie the attitude of therapeutic nihilism which is so often adopted towards patients who are wrongly thought to show a "purely endogenous illness."

Summary

Attention is drawn to the frequency of depressive states in war, which during the latter part of 1940 formed 13% of all admissions to a naval neuro-psychiatric unit.

The results obtained from the analysis of a series of 88 consecutive cases are recorded. No justification for a sharp and clearly cut division into "neurotic" and "psychotic" types could be found.

It is put forward that a more fundamental distinction would be between "affective disorders" (cases in which the mental and physical symptoms of either anxiety or depression, or both combined, are the main features) and hysterical reactions (in which the "escape" element predominates). Consequently it is more valuable to try to determine the presence and assess the intensity of genuine affective symptoms, and to contrast this with the presence or absence of hysterical features, than to contrast neurosis and psychosis. This is because the treatment of a predominantly affective reaction does differ fundamentally from that of hysteria, as does the type of personality that tends to be affected. As has been pointed out, the *proportion of firmness to sympathy should vary in direct* relation to the hysteria that is present in war cases; and, conversely, it is senseless to try to "keep in the firing line" genuine and severe affective states.

It was found in this series of cases that men of a fine type and excellent morale, but who for various reasons were deficient in adaptability, were, as the result of prolonged stress, prone to develop reactions which lay at the depressive end of the affective series. These depressions differed from those met with in civilian life by their rapid reactivity and better outcome. Thus, after a brief period of treatment, 25 patients (29%) were able to return to duty, and only 5 cases (6%) needed further hospital care. The prognosis and treatment of depressive states in wartime are discussed.

GENERAL PRINCIPLES OF TREATMENT OF AIR-RAID CASUALTIES*

BY

PHILIP H. MITCHINER, C.B.E., M.D., M.S., F.R.C.S

I must confess to a feeling of diffidence in dealing with the subject of the treatment of air-raid casualties, as owing to my administrative Army work I have had little opportunity of first-hand experience except during the period I was in Norway. I have, however, discussed the subject very fully with many colleagues from various hospitals who have considerable experience as surgeons under the E.M.S. in London and elsewhere, and am largely indebted to them for what I have to tell you.

Before proceeding to discuss the principles of treatment it is well to consider certain facts arising from experience in air raids on our cities, and the first and most outstanding fact is the small number of casualties compared with what was anticipated. Again, it is noteworthy that though the proportion of killed to wounded (I think seriously wounded only) is high—approximately one to two—the vast majority of those wounded suffer from very slight multiple wounds requiring no skilled surgical intervention, while of the seriously injured many are too ill to be helped by surgical skill. Thus the scope of surgery in air-raid casualties is very limited, though where it is justifiable it is often life-saving.

Head wounds are but seldom met with, though there is a most distressing, and all too frequently not fatal, injury—knocking away of part or even the whole of the face by bomb fragments owing to the victims not having

* A British Medical Association Lecture delivered before the West Somerset Division at Taunton, November 11, 1940.

thrown themselves *ventre à terre*. Therefore, when you hear bombs falling in your neighbourhood, forget your dignity and fall flat!

Principles of First Aid

First aid is performed on the spot by the first-aid squads, and very well they do it, too—with courage and without regard to the danger of falling shrapnel, bombs, and masonry. If I may be permitted one criticism of their work it is a tendency to take too long in carrying out unnecessarily elaborate first aid and bandaging, when it is far better for the victim to be treated quickly and conveyed as rapidly as possible to the warmth and cover of the hospital receiving-room or first-aid post. Arrest of haemorrhage, usually efficiently achieved by a pad and bandage, and the very rough splintage of fractures are all it is desirable to achieve "on the field." Tourniquets are seldom necessary, but if applied the doctor's attention should be drawn to them immediately the patient reaches hospital or a first-aid post.

I would bring the foregoing points especially to the notice of those who give first-aid instruction, and urge that these be impressed on their workers, as also the necessity of undressing victims as little as possible and keeping them warm by wrapping them up in blankets immediately the wound is dressed, thus minimizing exposure and wound shock (collapse). Another point I wish to stress is the necessity for training the squads to work in the dark or by the flickering light of a candle or the uncertain gleam of an electric torch; and, finally, the necessity for being able to do all this in a gas mask.

Reception of Wounded

It is my considered opinion that all cases should go to the reception-room of a hospital and there be seen and sorted by an experienced medical practitioner or surgeon. As stated, many of these cases receive multiple and apparently trivial wounds; and therein lies grave danger, for a cursory examination or an inexperienced eye may pass as superficial a small deeply punctured wound or be deceived by the apparent well-being of a patient with internal injuries, with serious and often fatal results. Lately I have seen two cases illustrative of this. In one of these a patient sent home from a first-aid post with multiple small and apparently superficial wounds died two days later from acute septic meningitis due to a fragment which had penetrated the brain through the left upper eyelid and orbital plate. In the second case a soldier, after bomb injury, walked a mile to the doctor and complained of a sinking feeling, which was attributed to a very natural fright. He was told to walk home, and later was found gasping, pale, and pulseless by the roadside. Subsequent operation revealed rupture of the liver and spleen, the result of blast. Too much stress cannot therefore be laid on the importance of careful but rapid sorting, or triage, as it is now fashionable to term it; and for this to be done efficiently experience and some system of coloured tabs is essential, so as to ensure precedence for cases of haemorrhage, open chest wounds, burns, etc.

Wound shock needs treating early and efficiently, and, though in mild cases warmth, rest, and hot sweet drinks may suffice, the addition of 1/4 to 1/3 grain of morphine is a valuable adjunct, while in all more severe cases blood transfusion, or serum or plasma transfusion in the case of burns or shock without wounds, is beneficial, and is expected by the lay public. Remember to rest such cases after treatment for at least half an hour before evacuation and do not usually give more than one pint of blood. Occasionally in severe cases a second given very slowly may be beneficial: the rate and volume of the pulse are the best guide to its necessity.

Team-work.—Here, as in all things, I wish to emphasize the value of team-work in ensuring the maximum of efficiency in the minimum of time—most essential in the rush of dealing with casualties in air raids, unless a "block" is to be created. Those concerned with stretcher-loading and unloading from ambulances, members of the refreshment department, the clerks, blood and burn and fracture teams, operating theatre staff, etc., must all be trained to work together, and if a particular worker is disgruntled or out of tune with his colleagues replace him (or her) at once.

Treatment of Special Injuries

The injuries met with include many varieties of wounds from bomb fragments and flying glass, crush accidents from falling masonry or burial under ruins, blast injuries, and burns from various sources.

Bomb Wounds.—These if bad lead to fatal results either directly or from their severity, such as in avulsion of an entire limb or evisceration; the majority of the remainder may be very slight and take the form of peppering with multiple small fragments, though of course injuries from medium-sized fragments are met with. It is obviously impossible to excise many small wounds, as the result would for practical purposes be a flayed patient. Such wounds must be more carefully examined to ascertain that no body cavity has been penetrated, and if any doubt exists, that particular wound must be excised and explored; otherwise the whole must be cleaned thoroughly and dressed with acriflavine or crude cod-liver oil ointment. No re-dressing should be carried out for at least ten to fourteen days, when healing will be found to have occurred in most cases. It is advisable to give sulphanilamide as a prophylactic against sepsis for the first four or five days.

Glass wounds may be very severe and deep, and are generally multiple. Sharp fragments will penetrate the skull and traverse the body cavities, doing as much harm to viscera as do bomb fragments.

Fractures are mostly of the open variety, and must be dealt with by free excision of the wound and fixation of the limb either by plaster-of-Paris or suitable traction apparatus. Much has been written about plaster-of-Paris as an immediate dressing. It is generally agreed that the results are good if the patient can be kept under observation for some days where the operation has been performed. Danger lies in infection and oedema under the plaster, causing gangrene of the limb: it is a very real danger, and if the patient is put in plaster this must be bivalved before evacuation. No one can say how long any patient will be in the ambulance, and there is not means to remove plaster on the journey. All fracture cases should be transferred as early as possible to special hospitals. As a general rule, for first aid all lower-limb fractures should be put up in a Thomas splint, and upper-extremity ones treated by Cramer's splinting and binding to the trunk for transport.

Thoracic Wounds.—Open pneumothorax must be closed at the earliest opportunity if death is to be averted. As a first-aid measure a large pad and a tight bandage must be applied at once and the patient be immediately removed to hospital, where very early operation is to be undertaken to cleanse the thoracic cavity and close the chest wall: such steps should precede any attempts at resuscitation. *Haemothorax*, not infrequently seen after blast and crush and through-and-through injuries, is best treated conservatively by rest and morphine, unless cyanosis or restlessness denotes respiratory distress, when aspiration must be performed promptly, and be repeated if necessary. Should subsequent infection ensue operative intervention will be carried out.

Abdominal wounds call for no special comment, save for the reminder that perineal or buttock wounds should be regarded with grave suspicion and the abdominal cavity be opened if any doubt is entertained that it may be perforated.

Treatment of Burns

Burns are common and are usually very severe, so that fatalities are frequent from this cause. Recently there has been great controversy as to the best method of treatment to employ; but, though I may be biased, I still think some form of tanning gives the best results and is most generally applicable. Shock is very severe in these cases, and needs prompt and thorough treatment both as a first-aid and as a resuscitant measure. Inasmuch as haemoconcentration can be demonstrated in these cases, transfusion of plasma or concentrated serum is preferable to whole blood, but the latter should be given if the others are not available. The fluid must be transfused slowly, as there is grave danger of fatal pulmonary oedema (for which reason intravenous saline is absolutely contraindicated), and may be repeated at intervals for the first few days—preferably by the drip method. The procedure is by no means easy in extensively burned patients, as superficial veins are not only hard to find but have a tendency to clot readily. As a first-aid measure tanning should be carried out promptly either by coating with tannafax or by applying a compress soaked in tea to the burnt area without any previous attempt to clean it other than removing charred clothing. It is a generally admitted fact that cases so treated remain fitter and suffer far less subsequent collapse. Hot sweet drinks and morphine should be given and the patient warmly wrapped and, if feasible, left lying quiet for half an hour before being evacuated in the ambulance.

At hospital, after treatment of the shock, scrupulous surgical cleansing of the burn, and, most important, the skin at its edges and six inches beyond, must be carried out promptly under anaesthesia, and all blebs opened and dead skin removed. Morphine alone is seldom sufficient in the rush, and can be supplemented safely by gas-and-oxygen anaesthesia; ether is too prone to cause pulmonary complications, and chloroform is too toxic to the damaged liver cells. Pentothal may be used in slight burns, but it is not always safe in severe ones owing to liver and kidney cell damage. Personally I now use a tannic acid compress, except for face, neck, and perineal burns, in which cases 1% aqueous gentian violet or powdered sulphanilamide is employed. Others, however, tan with silver nitrate and tannic acid, brilliant green, or albumin; while some apply cod-liver oil. Wakeley, Fleming, and Bunyan advocate warm saline-and-hypochlorite baths from the first, and the last-named has made ingenious silk casings to enclose the burnt areas so as to allow of frequent flushing over.

Lately there has been discussion on burns of the hands and fingers, it being claimed that tannic acid dressings cause necrosis and undue deformities. I can only say that in my experience I have not met these disasters. Necrosis subsequent to severe burns is not infrequent in the finger pulp, which often seems normal in appearance at first, and I suspect this may be responsible for the alarm and despondency of some of my colleagues. If this calamity is feared from the use of tannic acid then I suggest 1% aqueous gentian violet or even the saline baths advocated, though these are hard to manage except in a properly equipped hospital.

It will be seen that there is a good choice of methods of dressing burns. I cannot here discuss their merits or demerits; suffice it to say that as much care must be taken in preliminary cleansing as in wound excision; for this is essential if a good result is to be obtained. In any case, owing to the great tendency to sepsis, it is advisable to give sulphanilamide from the first for four or five days, and if the patient is vomiting it can be injected.

Sulphonamides

I may be expected to say something about the use of sulphanilamide and the sulphonamide group of drugs. It is my considered opinion that these drugs in some form—and personally I think prontosil is as good as any, and certainly as cheap—should be given for the first four or five days in all cases of wounds and burns, as it seems that the chances of sepsis supervening are then greatly diminished and its virulence lessened should it occur. The drug can be given by mouth in doses of 2 grammes thrice daily—increased to four-hourly if sepsis appears—and for the first twenty-four hours in warm lemonade or citric acid solution so as to increase the rapidity of its absorption into the blood stream. If this be done there is seldom necessity for intravenous or intramuscular injection of expensive forms of the drugs, such a procedure being reserved for cases with severe vomiting.

Toxic effects must of course be watched for, especially leucopenia, and their appearance calls for prompt cessation of the drug's administration. Local application to wounds in the form of a pack is popular with some surgeons, from 5 to 15 grammes being employed—never more: but only in exceptional cases does this seem likely to have any advantage over prompt oral administration, as the drug has no local action on the wound. As a dressing for burns of the face and perineum powdered prontosil has its advocates and uses: but here again a word of warning is necessary regarding the quantities it is safe to employ for this purpose.

EXPERIMENTAL HUMAN SCURVY

NOTES ON A REMARKABLE STUDY REPORTED BY CRANDON, LUND, AND DILL

BY

F. W. FOX, D.Sc.

(From the Biochemical Department, South African Institute for Medical Research, Johannesburg)

The following summary of an experiment carried out by a group of American investigators throws new light on the functions of vitamin C in human nutrition and on the problem of scurvy. It is of interest to compare and combine the results obtained with those reported by Fox, Dangerfield, Gottlich, and Jokl (1940).

Crandon, Lund, and Dill (1940) asked themselves the question, How long does it take a healthy adult to become scorbutic when fed on a diet otherwise fully adequate but entirely devoid of vitamin C? Crandon set to work to obtain an answer by experimenting on himself. The experiment was very carefully planned at the Medical School, Harvard, and was undertaken in close co-operation with several associated organizations and laboratories. This not only made it possible to carry out an extensive series of observations, but analyses were also duplicated by different observers and other valuable checks on the findings became practicable.

Crandon's Experiment

A normal active adult male placed himself on a vitamin-C-free diet, supplemented by all the other known dietary constituents, for a period of six months. The diet for the last four months consisted of bread, biscuits, cheese,

eggs, beer, black coffee, and a special chocolate; at the same time he received 30,000 I.U. of vitamin A, 132 I.U. of vitamin B_1, 80 µg. of riboflavin fortified by 10 Harris yeast tablets, 50 mg. of nicotinic acid, 5,280 I.U. of vitamin D, and, after the second month, 4 c.cm. of wheat-germ oil. Samples of blood were repeatedly tested in many ways, and numerous other means of investigating the response to the diet were found. The findings in this state of pure vitamin C deficiency—i.e., in the absence of factors such as multiple avitaminoses, infection, growth, or other stress—were as follows:

1. *Physical Findings.*—During the first four months all the physical findings were negative. There was, however, a fall in weight and a slight lowering of the basal metabolic rate, together with a feeling of easy fatigability and slight weakness.

2. *Loss of Weight.*—The subject experienced a gradual and continual loss of weight, which reached a maximum of 27 lb.—i.e., a loss of over 1 lb. a week. This was attributed to the type of diet that had to be employed rather than to the absence of vitamin C. No gain in weight was observed at the conclusion of the experiment when the subject received vitamin C though remaining on the same diet.

3. *Capillary Fragility.*—The Göthlin, Dalldorf, and Rumpel-Leede tests for increased capillary fragility were all negative, even in the presence of frank scurvy. While remarking that it must not be concluded from this that capillary fragility can be excluded as part of the underlying pathology of scurvy, it is pointed out that these tests must be regarded as poor indices of subclinical scurvy, even though in some cases petechiae may be produced which clear up on ascorbic acid therapy.

4. *Blood Chemistry.*—(*a*) The plasma ascorbic acid level rapidly fell and reached zero after forty-one days on the diet, remaining at this level *for thirteen weeks before the first evidence of clinical scurvy was manifest.* (*b*) The vitamin C level in the white cell platelet layer of the centrifuged blood fell gradually from the normal level, but did not reach zero until shortly before the appearance of clinical scurvy. (*c*) In spite of the nature of the diet and the loss of blood (estimated at over 6,000 c.cm. removed for various tests and during the operations) no anaemia developed. (*d*) The white cell count remained between 3,200 and 5,000 per c.mm. during the latter part of the experiment. The slight fall observed was not regarded as significant for this individual. (*e*) During six months of total deficiency and after a month of clinical scurvy the blood complement titre still remained normal.

5. *Resistance to Infection.*—There was almost complete freedom from respiratory infection throughout the experimental period, which included the winter months; in previous winters it had been not uncommon for the subject to suffer from frequent severe upper respiratory infections. This is thought to raise doubt as to whether vitamin C deficiency *per se* is an outstanding factor in lowering the resistance of an adult.

6. *Skin Lesions.*—(*a*) *After 134 days* had elapsed small perifollicular hyperkeratotic papules began to develop over the buttocks and the posterior aspects of the calves; there was also noticeable fragmentation of hairs. Each papule contained an in-growing hair, which could be seen if the hyperkeratotic plug was picked or scraped off, leaving a small slightly bleeding crater. Associated with these papules was a marked dryness of the skin, particularly over the extensor surfaces, and the backs of the hands became decidedly roughened, the pores standing out in exaggerated fashion. It is suggested that these hyperkeratotic papules may be the first signs of vitamin C deficiency. (*b*) *After 161 days* of the diet there appeared for the first time small perifollicular haemorrhages or petechiae over the lower legs. They seemed to occur in greatest numbers after the subject had been standing for some considerable time.

Following the administration of vitamin C all the skin lesions rapidly cleared.

7. *Teeth and Gums.*—(*a*) *At the end of the first five months* of the experiment a competent dentist pronounced the gums to be normal in appearance. (*b*) *Three weeks after the appearance of clinical scurvy* the gums were found to be slightly more boggy than usual, but no other gross changes could be seen. A biopsy of the gingiva was absolutely normal. However, radiographs of the teeth showed occasional interruptions of the lamina dura, and it is suggested that such *x*-ray pictures may be one of the better diagnostic criteria in early scurvy. At no time was there a trace of bleeding on brushing the teeth.

The lack of changes in the gums and teeth during the entire period of this experiment raises the question whether those commonly described as typical of scurvy may not, at least in part, be due to pre-existing or superimposed gingivitis or dental caries, or both. Supporting this hypothesis the fact is recalled that in edentulous scorbutic patients no gingival changes are commonly seen.

8. *Fatigue.*—A feeling of fatigue and weakness was first noticed at about the end of the third month, and became progressive as time went on. Careful tests at the Fatigue Laboratory indicated that after prolonged vitamin C deficiency there was impaired ability to perform *aerobic* work—e.g., walking and running on the treadmill. However, no great change could be found in the capacity for performing *anaerobic* work—e.g., in the muscular activity of the forearm as measured by an ergograph, both for single contraction and for contractions each second to exhaustion. Tests of moderate work (walking at 3.5 miles an hour) and a harder grade of work (a run to exhaustion at a rate of 7 miles an hour) were also employed. In the latter test the subject was able to run for only sixteen seconds when in the scorbutic state, whereas while on the same diet but when receiving daily injections of 1 gramme of ascorbic acid he ran for sixty-six seconds. It is stated that the performance while in the scorbutic state placed him in the category of men in the eighth decade of life, for whom a five-minute walk is maximal work. Another point of considerable theoretical interest was that after a period of aerobic work in the scorbutic state the rate of disappearance of the blood lactate was abnormally slow.

Attention is drawn to the possibility that extreme muscular exertion may deplete the body of the vitamin more rapidly and that scurvy might have appeared much sooner if the experimental subject had been constantly submitted to extreme muscular fatigue. Within twenty-four hours after the administration of ascorbic acid at the conclusion of the experiment a considerable alleviation of weakness and languor was noticed, but it is pointed out that part or even all of this improvement might have been due to suggestion.

9. *Wound Healing.*—These results are of the very greatest interest. (*a*) *At the end of three months* a sizable wound was made in the right mid-back of the subject. Approximately 2 grammes of the sacrospinalis muscle was removed for analysis and found to contain no vitamin C. In spite of this biopsy the wound ten days later showed good healing as compared with a normal control similarly treated but on an abundant supply of ascorbic acid. Moreover, histological study of the experimental subject's wound showed ample intercellular substance and capillary formation. (*b*) *At the end of 182 days*—twenty-one days after the petechiae had become apparent over the lower limbs—a similar wound was again made in the left mid-back. Healing appeared to progress normally, but on the tenth post-operative day a biopsy was made, and it was found that beneath the skin, which appeared well healed, there was no healing of the wound, which was filled with unorganized blood clot. Sections of this wound showed a lack of intercellular substance and capillary formation, as has been found by Wolbach in the wounds of scorbutic guinea-pigs. It was because of this finding that the experiment was discontinued and the subject was given a daily injection of 1 gramme of ascorbic acid though remaining on the same diet. After several days of vitamin therapy another biopsy showed good healing, with ample intercellular substance and capillary formation.

10. All the signs and symptoms of scurvy rapidly disappeared following the intravenous injection of ascorbic acid.

11. *Daily Requirements of Ascorbic Acid.*—After the beginning of treatment with ascorbic acid it was found from urinary excretion tests that from 4 to 6 grammes was required to resaturate this individual. Since the first signs of scurvy

appeared after 132 days of total vitamin C deficiency it was concluded that the maximal daily utilization of this vitamin lies between 30 and 45 mg., though it was suggested that the true requirements may lie somewhat below this figure.

In conclusion the authors express the opinion that the long interval that elapsed before clinical scurvy made its appearance is probably due to the absence of any complicating factors, such as growth, infection, or multiple avitaminosis. They also remark that, apart from being a prerequisite for the formation of intercellular substance, the part which vitamin C plays in the physiology of the human organism remains conjectural; however, certain findings, such as the abnormal blood lactate values obtained after exertion, may serve as leads for further investigation.

Comment and Comparison with our Findings on Native Mine Labourers

The remarkable nature and practical importance of this study will have been appreciated from the foregoing summary. Not only does it illustrate the possibilities now becoming available for isolating the part played by a single vitamin, but the fact that the experimental subject was a healthy human being and not a laboratory animal gives the findings great significance.

Comparing these results with those gained from our own study of native mine labourers, it will be seen that the two are complementary in a very interesting way. We studied for seven months nearly a thousand healthy men on a low but not entirely deficient daily intake of ascorbic acid. The American investigators studied intensively for six months one healthy man on a diet totally devoid of this vitamin. The results of the two studies may be compared and combined as follows:

(*a*) Total deficiency failed to produce clinical symptoms of impaired health over a period of three months, during which time the subject was draining upon his stores of vitamin; in our case a low daily intake gave equally negative results over a period of seven months in individuals who were shown to have very low initial reserves of vitamin.

(*b*) In neither case could any increase in capillary fragility be detected by the usual tests, even when frank scurvy had developed.

(*c*) Determination of the ascorbic acid level of the blood proved of no help in relation to the clinical findings. With total deprivation it rapidly fell to *nil*; with partial deprivation it remained at such low levels that they could be detected only with difficulty. Yet in neither case was there any clinical indication of ill-health.

(*d*) There was no indication that a deficiency of vitamin C leads to the development of anaemia.

(*e*) In both investigations the gums remained healthy throughout.

(*f*) There was no indication that resistance to infection had been diminished by the reduction in the intake of vitamin C.

(*g*) In both experiments gross diminution in the amount of vitamin C provided in the diet revealed no impairment in the healing of wounds. In fact, no less than six months of total deprivation was required to bring about such impairment.

(*h*) This demonstration that deprivation of ascorbic acid, unless extremely severe and prolonged, does not of itself lead to the appearance of scurvy in the absence of precipitating factors supports the conclusion already arrived at by Hess and others. It is also strikingly borne out by our findings, since only twelve out of our large groups contracted the disease, though all were on the same long-continued and low daily intake of vitamin.

(*i*) It will be noted that it took no less than three months of complete deprivation of dietary vitamin C to produce a feeling of languor and incapacity for strenuous work; and even this may well be partly accounted for by the considerable loss of weight associated with the diet used. It is surely of significance here that no similar indications were obtained with our subjects when living for so long on such a low daily intake. Still more significant was our finding that scurvy did not develop either more quickly or more often among those engaged on really strenuous work. While it will be agreed that frank scurvy is characterized by pronounced languor and incapacity for work, both studies appear to indicate that the intermediate stages are not so characterized. Indeed, it seems somewhat curious that modern writers lay so much emphasis on hard work as a predisposing factor in the precipitation of scurvy. This was not the view of the classical students of the disease. Thus Hess (1920) writes: "Lind and others repeatedly emphasize the fact that the indolent and slothful sailor was stricken with scurvy far oftener than the one who was active, and claimed that physical exercise even tended to bring about a cure."

(*j*) Neither study enables us to establish with any certainty what are the daily requirements of ascorbic acid necessary to maintain good health. Arguing on the amount required to saturate the subject at the *conclusion* of the experiment (4 to 6 grammes) the American investigators suggest that the maximal daily utilization must have been between 30 and 45 mg., or possibly lower, since the first symptoms of scurvy appeared after 132 days. However, this estimate cannot be regarded as very satisfactory, since there is no record that the subject was saturated at the start of the experiment; and, indeed, the initial plasma level of only 1 mg. indicates that this was probably not the case.

On the other hand, our own experience indicates that remarkably good health could be maintained on 15 mg. of ascorbic acid, or possibly a little more, daily, and this level is in agreement with that estimated by Kellie and Zilva (1939) using entirely different methods. It seems, too, that the lower estimate is more in accord with everyday experience, since such large numbers of people live on diets that can hardly contain more than this amount, if as much. Taken together, the two investigations lend no support to the assumption, so commonly made, that large amounts of the vitamin would improve the general standard of health, though the *precarious* nature of such meagre supplies is equally clearly demonstrated.

Conclusions

Several other valuable conclusions can be drawn from this study:

1. The observation made by Wiltshire (1919) that in a large proportion of his cases of scurvy the appearance of follicular keratosis provided the first recognizable sign of the scorbutic tendency, and would have enabled a diagnosis to be made before the onset of symptoms, receives striking support. In future more attention should obviously be given to this simple clinical sign.

2. Estimation of the ascorbic acid content of the white cell platelet layer of the centrifuged blood appears to provide us with a reliable method of investigating subclinical scurvy, for it only fell to zero shortly before the appearance of clinical symptoms.

3. The role of ascorbic acid as a prerequisite for the formation of intercellular substance has now been established for the human subject.

4. There are indications that ascorbic acid may be concerned with the rate of disappearance of the blood lactate that accumulates during the performance of physical work.

SERUM CHOLESTEROL AND IRRADIATION SICKNESS

BY

BARBARA E. HOLMES, Ph.D.

(From the Imperial Cancer Research Fund and the Mount Vernon Hospital, Northwood)

The occurrence of sickness and other unfavourable reactions after treatment by *x* rays is no longer a major problem. Careful attention to ventilation, localization of the irradiation, and regulation of the intensity of each dose have very much reduced both the incidence and the severity of *x*-ray sickness. Nevertheless cases do still occur, and no satisfactory or conclusive explanation has yet been offered. They must obviously be of interest to anyone concerned with the general physiological and biochemical effects of irradiation. Symptoms caused by direct irradiation of the stomach or intestines are not under consideration here, and may obviously fall into a quite different category.

The extensive literature on this subject has been reviewed by Rolleston (1930–1), by Colwell and Russ (1924), and by Dodds and Webster (1924). Here it is only necessary to quote Levy-Dorn and Burgheim (1926) and Burgheim (1927). These authors observed in some cases a sharp fall of serum cholesterol after *x*-ray treatment, followed by vomiting. Cases not suffering from unfavourable symptoms showed no fall in serum cholesterol. Burgheim obtained good results by administering cholesterol as a preventive of *x*-ray sickness, and was therefore inclined to consider that a direct relation existed between the low level of serum cholesterol and the symptoms observed. Other authors have been unable to confirm these results.

The following series of cases may to some extent explain this discrepancy. The series is far too small to permit any conclusions to be drawn from it alone (war conditions make it very difficult to obtain further cases), but it may be of value when considered together with the work of Burgheim and of others.

The Present Investigation

The blood sera examined were obtained at the Mount Vernon Hospital, Northwood, with the kind collaboration of Dr. Perkins. Samples of blood were taken by her before irradiation and at the stated intervals afterwards. When it was necessary to keep the samples overnight she drew off the serum and stored it in the ice-chest. It was found that if whole blood is stored there may be a considerable loss of cholesterol.

Irradiation was carried out every day for a given period and the samples here estimated were taken before and after the first two irradiations of such a series. Where no sample was obtained before irradiation the approximate value was assumed to be that obtained in the sample twenty-four hours after irradiation, as these were often found to be the same. This twenty-four-hour sample is also the pre-irradiation sample for the second irradiation.

The method used was that of Leiboff (Peters and van Slyke, 1932). Table I shows that the most usual reaction to the first and often the second irradiation is a considerable rise in serum cholesterol. This rise was stressed by Burgheim, who considered it (personal communication) to be due to cholesterol leaving the tumour after irradiation.

Table II shows that an increase of serum cholesterol did not appear in four cases in which vomiting occurred, but that there was actually a considerable fall. To this extent these figures agree with the result obtained by Burgheim. It will be noticed, however, that there is not necessarily any direct relation between the fall in the serum cholesterol level and the onset of the symptoms. In Case K., for instance, the fall in cholesterol did not occur until after the second irradiation, whereas the vomiting began after the first irradiation, and in Case F. there was still vomiting nearly twenty-four hours after the first irradiation, when the cholesterol value had returned to normal. In Case N. the change was far too small to account for any symptoms; Case W. in Table I, in which no vomiting occurred, showed a slightly greater fall. Other isolated observations—not included in the tables, as they are single estimations and not a series on each case—serve to support the view that there is no direct relation between the serum cholesterol level and the symptoms after irradiation. Thus the serum cholesterol of patients on admission shows very wide variation, being sometimes present in minute traces only. Again, in three cases samples taken shortly after vomiting show normal or even high cholesterol values.

TABLE I

Case	Site	Cholesterol (mg. per 100 c.cm. of serum)			
		Before 1st Irradiation	5 Hours After	Before 2nd Irradiation (24 Hours After 1st)	5 Hours After
P.	Uterus ..	115	200	130	143
C.	Pelvis ..	110	208		
S.	Breast ..	50		50	140
A.	Oesophagus		40	34	59
M.	,,		107	61	160
W.	Breast ..	80	53		53
D.	Vulva ..		86	113	125

TABLE II

Case	Site	Cholesterol (mg. per 100 c.cm. of serum)			
		Before 1st Irradiation	5 Hours After	Before 2nd Irradiation (24 Hours After 1st)	5 Hours After
B.	Uterus ..	100	60 Vomiting		
F.	,,	143	69	140. Vomiting	62 Vomiting
K.	Dorsal spine	200	200 Vomiting		83
N.	Left thigh		67 Slight. vomiting	78	66

In conclusion it can be said, taking these few cases together with those of Burgheim, that in patients liable to *x*-ray sickness there may be a tendency for the serum cholesterol level to fall. Any direct relation between the amount of cholesterol in the serum and the symptoms observed, or any definite time-relation between the two, cannot be substantiated, this probably accounting for the fact that some workers have not confirmed the results of Burgheim. It may well be that some factor concerned with the production of the symptoms tends also to produce a change in metabolism leading to a loss of cholesterol from the blood.

My thanks are due to Dr. Perkins for her kind collaboration and to Dr. Fairchild of the Mount Vernon Hospital for providing us with material.

ABDOMINAL HYPERAESTHESIA IN ARMY DYSPEPTICS

BY

W. G. MILLS, M.B., Ch.B.
Captain, R.A.M.C.

In a leading article in the *Journal* of December 14, 1940 (p. 836), the problem of the disposal of the dyspeptic soldier was discussed, and it was clearly demonstrated that such a man is likely to be a permanent liability to the Army, since a continued light diet is seldom a practical measure on active service. The statement that "it is highly questionable whether men with a prolonged history of organic dyspepsia . . . should be allowed to join the fighting Services" will be endorsed by every unit medical officer; but once a man is enlisted it rests with the medical officer to determine what is a "prolonged history" and what is "organic dyspepsia." The article continues: "The doubtful case should be handled by the expert gastro-enterologist and investigated by every known means at our disposal," which is certainly a counsel of perfection. But the unfortunate M.O. meets "doubtful cases" every morning on his sick parade, ranging from the man who is honestly worried by a slight feeling of distension after his generous midday rations to the true malingerer who "knows all the answers" and is now happily rare. The commonest case to meet is the man who feels it is always worth "trying it on" the new M.O.

It is manifestly impossible for every man complaining of abdominal discomfort to be fully investigated by an expert gastro-enterologist, and in the absence of gross vomiting or definite physical signs the persistent importunity of the patient is the most potent factor in securing the desired period of residency in hospital. Hence it was felt that some test which could be easily applied by the M.O. would be invaluable in sorting out organic disease without it being in any way necessary to establish an exact diagnosis—some way, in fact, to diminish the number of men sent in to military hospitals for radiography, diet, and observation, a process which often takes many weeks.

Technique of the Investigation

The old test of abdominal hyperaesthesia was used and findings correlated with radiography. Thirty cases of dyspepsia admitted for investigation to one ward of a military hospital were examined physically and radiologically. The only common factors were the complaint of dyspepsia and the exhaustion of the patience of the M.O. Service varied from 17 years to 3 months, the age limits were 24 and 53, and symptoms had been present from 5 weeks to 16 years.

After routine oral and abdominal examination the test for hyperaesthesia was conducted with the man's own four-pronged dinner fork; this was drawn down the front of the chest and abdomen, from nipple level to Poupart's ligament, in vertical lines repeated from right to left, the patient being instructed to indicate should he feel anything unusual. This was followed by similar strokes from below upwards, and others horizontally round the abdomen. It was significant that the majority of men appeared profoundly sceptical at first, but were amazed to find themselves calling out spontaneously at the change of sensation experienced; few could describe the phenomenon accurately, but such remarks as "It went sharper," "Like an electric shock," and "A tingling sort of feeling" were common. Especial care was taken throughout to keep the fork at the same angle to the skin when the costal margin was traversed, as the zones of hyperaesthesia were often encountered in this site.

Results

Only 7 out of the 30 patients examined failed to show an area of hyperaesthesia; such a proportion is accounted for by the method of selection, since every one had convinced some M.O. that he had an organic gastric lesion. However, the presence of hyperaesthesia was found to be much more constant than the shape of the area, and it was eventually decided to classify cases purely into upper abdominal and lower abdominal areas, and unilateral or bilateral. The former distinction was invariably obvious, since no area occupied both the hypochondrium and the iliac fossa, and the para-umbilical zone was rarely affected.

TABLE I.—*Site of Hyperaesthesia (30 Cases)*

Supra-umbilical—bilateral	9
" " —right only	11
" " —left only	1
Infra-umbilical—right only	2
" " —left only	0
No hyperaesthesia	7

Radiological investigation was carried out to determine the connexion between hyperaesthesia and the organic condition of the stomach as demonstrable by radiography.

TABLE II.—*Results of Barium Meal Radiography*

A. Without hyperaesthesia (7 cases):	
Normal stomach and duodenum	3
Some degree of gastroptosis	2
Evidence of old duodenal ulceration, probably healed	2
B. Upper abdominal hyperaesthesia (21 cases):	
Duodenal ulcer demonstrable	12
Gastric ulcer demonstrable	2
Spasm suggestive of ulcer	2
Gastroptosis	1
Gastritis present	4

Each of the two cases with hyperaesthesia in the right iliac fossa showed a slight pylorospasm on radiography.

Comment

Fourteen cases of upper abdominal hyperaesthesia had peptic ulceration confirmed by radiography; the hyperaesthetic area was typically situated below the ninth right costal cartilage, with often a similar area of less intensity on the left; the only case with purely left-sided signs showed a gastric ulcer of the lesser curve.

Seven further cases with hyperaesthesia had abnormal radiographs, and taking into consideration the previous history and present symptoms there was enough evidence for reference to medical boards.

Two cases of chronic appendicitis had attention focused upon them by the discovery of hyperaesthesia in the right iliac fossa.

Of 7 cases without hyperaesthesia the radiographs were normal in three and revealed gastroptosis in two; in the other 2 cases, 1 had had an old ulcer but had been symptom-free for over a month, while the final case still had symptoms.

Conclusions

From the varying nature of the lesion which can produce right hypochondrial hyperaesthesia it is evident that no peritoneal involvement is needed for the production of the sign; yet the fact that not one case with hyperaesthesia presented a radiograph that could be classed as normal must be evidence that some organic disturbance of the mucous membrane or musculature is necessary for its production. Whether such a lesion will necessarily be severe enough to justify "boarding" a man out of the fighting Forces is debatable, but we draw the conclusion

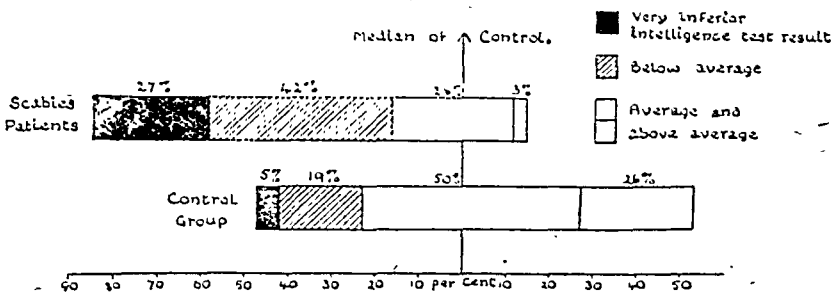
that the presence of upper abdominal hyperaesthesia in an Army dyspeptic is sufficient to warrant hospital investigation.

Summary

Abdominal hyperaesthesia has been tested in 30 Army dyspeptics suspected of peptic ulceration.

Its presence has coincided considerably with abnormal radiological findings.

It is claimed that such a test may give R.A.M.C. officers in charge of troops some clear indication of which dyspeptic cases will require hospital investigation and which may be retained with the unit.



THE INCIDENCE OF SCABIES AND ITS APPARENT DEPENDENCE UPON SUBNORMAL INTELLIGENCE

BY

GEOFFREY A. HODGSON, M.D.

Captain, R.A.M.C.; late Medical Officer, Imperial Chemical Industries Ltd.

Scabies constituted the greatest single cause of incapacity among troops stationed in 1915 in the United Kingdom (*Official History of the Great War*, 1931). It was noted that from 1916 to 1920 the ratio of cases occurring in France to those in the United Kingdom was about 20:18, the observation suggesting that the insanitary conditions of trench warfare were less important as an aetiological factor than is commonly supposed. Recent clinical experience suggested that the man who is most likely to contract scabies is the "dullard" or the mental defective.

Accordingly a preliminary sample of 100 unselected scabietic patients has been examined to assess their intelligence. The results have been compared with those obtained in a control sample of 500 consecutive recruits at a R.A.M.C. depot tested in the same manner. The test employed was the R.E.C.I. progressive matrices (Penrose and Raven, 1936; Raven, 1939), the sets A, B, and C being used, as these give a high degree of differentiation between individuals of average and those of below average intelligence. The validity of each score was confirmed by comparing the marks in each set with the expected "break-up"—i.e., distribution of marks between the three sets. With a possible total score of 36, the middle 50% of the scores in the control group fell between 27 and 32 inclusive, the median being 30; and these scores were considered "average." The 5% scoring 19 or less were termed "very inferior," the 26% scoring between 33 and 36 "above average." The same score standards were adopted in grouping the scabietic patients, of whom only 14% scored above the median of the control group. The table shows the comparison between the groups.

Marks	Control	Scabies	Group
0–19	5%	27%	"Very inferior"
20–26	19%	42%	"Below average"
27–32	50%	28%	"Average"
33–36	26%	3%	"Above average"

Thus it is seen that the scores of 27% of the scabietic patients lie in the "very inferior" group—i.e., low enough to warrant the suspicion of mental defect; while those of another 42% fall below the "average" range; only 3% achieved "above average" scores. The differences are shown diagrammatically below.

Although the investigation of a comparatively small series is inconclusive, the results suggest a close correlation between the incidence of scabies and that of subnormal or defective intelligence.

Discussion

Scabies prophylaxis in the Army includes regular bathing, avoidance of overcrowding in billets, disinfestation of blankets, clothing, and latrines, the inspection of troops, and the treatment of developed cases in isolation. Nevertheless, the high incidence continues. Some cases undoubtedly come from propinquity or from infection acquired at home whilst on leave. Personal uncleanliness predisposes to infection, and a large number of scabietic patients have dirty clothes, dirty skins, and dirty habits. At home stations the majority of troops are within reach of normal sanitary amenities, but some men remain dirty however good the facilities and however strict the discipline. These men are usually of much below average intelligence. Such men may well form a nidus, infecting from time to time their more intelligent fellows. To rid the Army of the mentally defective would go a long way toward ridding it of scabies.

This inquiry is continuing on a larger scale, and venereal disease, pediculosis, and other cutaneous diseases are being investigated similarly.

Summary

100 unselected scabies patients and a control group of 500 consecutive recruits have been submitted to an intelligence test. Scores suggesting subnormal and low-grade intelligence were found in great excess among the scabietic patients.

I wish to thank Lieut.-Colonel P. Dwyer, *M.C.*, R.A.M.C., for giving facilities for the investigation, and the Officer Commanding No. 11 R.A.M.C. Depot and his staff for their assistance in providing the control series. I am indebted to Major G. R. Hargreaves, R.A.M.C., for his kind and helpful collaboration.

J. D. Rolleston (*Clin. J.*, 1940, **69**, 321), who emphasizes the rarity of laryngeal diphtheria in adults, has collected twelve cases in adults aged from 22 to 76, including one of his own in a woman aged 76. Five were in men and seven in women. In five the larynx only was affected, in six the fauces as well, and in one no details were given. Intubation was performed in two, tracheotomy in one, laryngotomy and tracheotomy in one, intubation and tracheotomy in one, and no operation in seven. In five the laryngeal symptoms were confined to loss of voice and a croupy cough, which helps to explain the unusually low mortality in the present series. The death of George Washington at the age of 67—which has been variously attributed to laryngeal diphtheria, Vincent's angina, Ludwig's angina, tuberculosis, pneumonia, and cancer—was most probably due to septic sore throat.

Clinical Memoranda

Effect of Vitamin A on the Secretion of Gastric Juice in Deficient Hydrochloric Acid Production

E. Schiödt (1934, 1935) has called attention to the changes in the digestive tract produced by vitamin deficiency. He says that lack of vitamin A causes atrophy of the gastric mucosa while lack of vitamin B is followed by achlorhydria and lack of vitamin C by gastric ulcer. R. Boller (1936a, 1936b, 1937) found that if 10 drops of vitamin A solution in oil were given an hour before an alcoholic test breakfast the resulting acid values in normal and subacid people were increased. He also observed that cases with symptoms of achlorhydria or insufficient acid production were benefited by giving vitamin A continuously. His observations were confirmed by G. W. (1936).

It seemed desirable to investigate these results with a view to the constructive treatment of inadequate acid production. We therefore studied the effect on the gastric acid of a single

TABLE I

Case No.	Maximal Acid Value without Previous Vitamin Administration		Maximal Acid Value after Previous Vitamin Administration		Result
	Free	Total	Free	Total	
1	2	22	5	24	Positive
2	24	36	45	56	Negative
3	8	16	8	20

8	0	8	0	8	
9	0	10	0	12	
10	8	26	4	12	

dose and of continuous administration of vitamin A. The first part of the investigation was carried out as follows, the results are shown in Table I.

Patients were selected by giving a fractional test breakfast of 20 cg. of pure caffeine in 200 c.cm. of water; those who showed decrease or insufficient production of hydrochloric acid were then given 20 drops of vitamin A solution thirty minutes before the test meal. The solution used was "Virgin," supplied to us by Messrs. Wander Ltd.; it contains 40,000 international units in 20 drops. In only 3 out of 10 cases did this single dose produce an increase of the hydrochloric acid in the gastric juice; but 3 of the negative patients were subsequently treated with continuous dosage, and all of them then lost their symptoms and showed normal acid values after test meals.

We have treated 20 cases of achlorhydria or hypochlorhydria by giving vitamin A for two or three weeks. In 12 cases symptoms improved, weight increased, and the fractional test breakfast showed an increase of total acid and of free hydrochloric acid (Table II). The patients who responded to this treatment were suffering from chronic gastritis, diabetes mellitus, Graves's disease, renal lithiasis, gastroptosis, and neurasthenia. In other words they all had a chronic inflammation of the gastric mucosa or else their deficient acid secretion was secondary to the functional alteration of some other organ. Those who failed to respond were suffering from gastric cancer (1), pernicious anaemia (2), and disorders of bile secretion or excretion (5). In cancer and pernicious anaemia the gastric mucous membrane is so atrophic that no effect could be expected, but the reason for resistance of achlorhydria associated with disorder of the biliary tract is less obvious. We assume that the absorption of vitamin A, a fat-soluble substance, may be influenced by such anomalies in the same way as fat digestion and fat resorption generally.

To test this hypothesis we treated a histamine-anacid patient, suffering from cholelithiasis, with simultaneous administration of 0·5 gramme of sodium taurocholate and vitamin A three times a day for two weeks. Previous administration of vitamin A alone for two weeks had been ineffective. On the combined dosage the test breakfast showed a free-acid figure of 8 and total acid 20. Although conclusions cannot be drawn from one case, it seems justifiable in such cases to exhibit vitamin A together with bile salts.

We were able to follow up 2 cases: No. 8 in Table II was still improved after six months, but the other, which had been treated with taurocholic acid as well as the vitamin, relapsed to complete achlorhydria.

Summary

Moderation or total alleviation of the symptoms of achlorhydria or hypochlorhydria may be obtained by the administration of vitamin A. For private practice this may conveniently be given as four tablets (16,000 I.U.) three times a day for two weeks, then two tablets (8,000 I.U.) thrice a day for a further two weeks, repeating the course after an interval of four weeks.

Test meals show a considerable increase of free acid and total acidity after such treatment, and there is also increase of weight.

Intrathoracic Use of Sulphanilamide in Empyema

The following case seems to be interesting enough to merit publication.

CASE REPORT

On October 28, 1940, I saw a man aged 55 who had acute pleuritic pain and some dullness over the lower lobe of his left lung. The next day the diagnosis of left basal pneumonia and severe pleurisy was established. The evening temperature was 103.8°. During the following week he was very ill, and poisoned, and I suspected that empyema was developing. He absolutely refused, after the second day of his illness, to go on taking sulphapyridine (M & B 693) tablets, as he felt so nauseated, ill, and miserable.

As there was no fall of temperature on the eighth day I explored his chest, but only got some blood. On the eleventh day I again explored, and found stinking pus in the lowest part of his pleural cavity. Aspiration was at once done, and about 9 oz. was drawn off. As the patient was too ill to wait for further aspirations I drained his chest the next day, using the closed method, with the end of the tubing in a bottle of dettol solution. The pus evacuated smelt horribly. Soluseptasine was given intravenously, and his temperature came down to normal for one day, then rose to 100.6°. Prontosil by mouth was not tolerated, so I persisted with soluseptasine injections. His condition was very unsatisfactory: his face was grey and puffy. The discharge was still foul and copious, although the drainage was satisfactory.

Nine days after his operation I crushed six 0.5-gramme tablets of sulphanilamide (prontosil album), suspended them in sterilized water, and injected the drug through the drainage tube. The next day there was a dramatic improvement in his colour and the discharge was much less and not offensive. He had four more similar injections in the next nine days; then the tube was removed and the wound dried. His temperature became normal seven days after the change of treatment.

For local treatment of wounds sulphanilamide is now used extensively, but I have not noticed a record of its use for empyema.

HARRY GABB, M.B., B.Ch.,
Late Surgeon, Royal East Sussex Hospital.

J. Mioni (*Thèse de Paris*, 1940, No. 324) states that acceleration of the sedimentation rate is never a premonitory or initial sign in diseases of the joints. It never precedes the development of clinical manifestations, but as it may accompany these manifestations it enables the organic nature of the symptoms to be affirmed. In the absence of any morbid association the acceleration of the sedimentation rate justifies the suspicion that a patient with painful symptoms is suffering from a highly inflammatory process such as acute articular rheumatism, subacute rheumatism of a chronic and generalized character, spondylose rhizomélique, or gout. The intensity of the sedimentation rate is generally in proportion to the acuteness, intensity, and extent of the inflammatory manifestations, but their clinical expression may have disappeared when the sedimentation rate is still accelerated, thus indicating that the causal process has not yet finished.

Reviews

CLASSIFICATION OF TUMOURS

Debatable Tumours in Human and Animal Pathology. By W. F. Harvey, E. K. Dawson, and J. R. M. Innes. (Pp. 124; illustrated. 10s. 6d. net.) Edinburgh and London: Published for the Cancer Control Organization of Edinburgh and South-East Scotland by Oliver and Boyd.

This is the first of a projected series of memoirs to be published under the auspices of the Cancer Control Organization of Edinburgh and South-East Scotland, and consists of slightly revised versions of papers which originally appeared in the *Edinburgh Medical Journal*. Nine tumour-classes are dealt with under the headings: Seminoma, Granulosa-cell Tumour of the Ovary, "Mixed Tumours" of the Salivary Glands, Melanoma, Lympho-epithelioma, Giant-cell Tumour of Bone, Endothelioma, Lymphosarcoma, and Meningioma. Material from a very large number of tumours has been available, and a determined attempt has been made to discover and define the natural limits of each of the classes selected for study. The result is a series of concise descriptions of the range of tissue abnormalities which, it is thought, must be considered as belonging to each of these several classes.

Reports of prolonged and intensive studies such as these serve at least one useful purpose not contemplated by their authors, for they illustrate the difficulties which beset attempts to reach a completely logical and consistent classification of tumours on the basis of cellular affinities—the basis usually accepted. No better basis is known. But do we always realize what it is that we attempt? Secondary classifications are determined, for instance, by the degree to which tissue-forming, functional, or invasive qualities are actually exhibited in the developed tumour. Our primary object, however, is to group together tumours which have arisen from like cells—that is, from cells which, starting from the fertilized ovum, have followed a similar line of differentiation and, within reasonable limits, to a similar degree. These characters we must deduce from histological examination of the developed tumour, well aware the while that an unknown degree of cell differentiation or of cell dedifferentiation may have taken place at or since this elusive normal cell first took on malignant characters and thus became ancestor of all the tumour cells in the mass before us. Harvey, Dawson, and Innes escape the difficulty, so far as tumours of highly differentiated tissues are concerned, by assuming that in such tissues there is normally present a residuum of embryonal cells from which all cell-replacements come and from which all tumours arise. Such a conception seems of necessity to imply that as a rule much differentiation occurs at or after the time of tumour inception. Most workers have felt impelled to the view that tumours do often arise from highly differentiated normal cells and that quite commonly there is a demonstrable reversion to simpler type, rather than an increased degree of specialization, as such tumours grow and spread.

One of the very disturbing difficulties which arise in classifying tumours according to cellular likenesses is illustrated in the fact that Harvey, Dawson, and Innes feel themselves logically bound to include at least some forms of granulation tissue in their "giant-cell-tumour-of-bone" class and to place in the "melanoma" group conditions which most have regarded as simple malformations. Reflecting on all this one has the uneasy feeling that possibly our efforts at consistent classification are largely vitiated at present by the absence of important information of unknown nature. After all, the characters

we use in the classification of tumours are simply characters which may be exhibited by the corresponding ordinary normal cells when given the right conditions. The characters are no innovations—as witness the difficulty found in deciding, given an isolated cell, whether that cell is malignant or not. Short, perhaps, of tissue-invasive activities, all we really observe are various non-specific manifestations of cell activity. One feels that perhaps real improvement may come only when use can be made of features truly peculiar to the malignant condition itself—that is, to the reason for the malignant condition. Appreciation of the essential unity of the various scrofulous conditions had to await the discovery of the tubercle bacillus, and the essential manifestations of scurvy were not precisely defined until the discovery and identification of "food factors." What is the equivalent in tumours? Are we, indeed, even viewing the problem right? Unfortunately discussion of such general problems falls outside the purpose of the book under review.

It is convenient to have these papers accessible in collected form. They will be consulted by specialists. They are clearly and tersely written, contain an abundance of excellent illustrations, and provide extensive bibliographies. Authors and publishers are to be congratulated.

MEDICAL CHEMISTRY

Exposés Annuels de Biochimie Médicale. Published under the direction of Michel Polonovski. Second series. (Pp. 264. 75 francs.) Paris: Masson et Cie. 1939.

This volume, the second of its kind, comprises a series of twelve addresses on subjects belonging to the domain of medical chemistry, delivered by eminent biochemists at the Faculty of Medicine, Paris. Each is designed to convey to an audience not necessarily well versed in the subject an understanding of the position which has been reached by recent scientific investigation, and also the stages by which the most important advances have been made. Readers will note that the subjects are presented in a vivid and fascinating way, and where some of them are inherently difficult every care has been taken to make them easy to comprehend. Many of the contributors are of world-wide repute, and their names are an assurance of the authoritative nature of their expositions. The opening lecture is by A. Szent-Györgyi, than whom there is no greater expert on the subject of biological oxidations. Discussing the outstanding work of Warburg, Wieland, and Keilin, with an occasional modest reference to the results achieved in his own laboratory, he traces out the progress of the last ten years, which has quite revolutionized our knowledge. A discourse by E. J. Bigwood on objective methods of studying deficiency disorders in respect of vitamins A, C, and D, with special reference to their use in the recognition of subclinical states, is of more direct medical interest. Regarding C-deficiency, both chemical titration methods employing dichlorphenol-indophenol and methods based upon the measurement of capillary resistance receive special attention. Structural organic chemistry plays an important part in the pages devoted to the hormones of the adrenal cortex, but there is also a good deal about biological test methods applied to the study of cortical activity. P. Florence reviews the subject of uric-acid metabolism, a field in which he shows that there are a number of interesting problems awaiting solution.

Other lectures cover such diverse topics as immunochemistry, the chemical constitution of the enzymes, virus proteins, and the biochemistry of magnesium. It is not possible in this brief space to do more than give some idea of the contents, and to add the opinion that for its clear, readable accounts of present-day knowledge in all these spheres the volume is worthy of attention from English readers who are able to procure a copy, particularly as there is nothing quite analogous to this publication in our own language.

SOCIAL APPLIED SCIENCE

The Century of Science, 1840–1940. By F. Sherwood Taylor, Ph.D., M.A., B.Sc. (Pp. 230. 8s. 6d. net.) London and Toronto: William Heinemann, Ltd. 1941.

It is curious that the publishers of *The Century of Science*, by Dr. F. Sherwood Taylor, in their advertisements of the book in the newspaper press and even in their slip accompanying copies sent for review, should mis-state its title as "A Century of Science"; for in this case the definite article is significant. The author deals not with science in general during a period of a hundred years, but with the practical applications of science to domestic, industrial, and social life during the century in which those applications have been revolutionary in their effects upon the habits and beliefs of civilized man. This century, with justice, he takes to be the years 1840 to 1940. The author, not a medical man, has written two previous books—*A Short History of Science* and *The World of Science*, which have been highly praised, and his present volume equally demonstrates that he possesses powers of selection, summarization, ordering, and narration which are exceptional. The earliest science of Egypt and Mesopotamia was applied science. During subsequent years there were philosophers, like Roger Bacon and Francis Bacon in England, who thought of the prime purpose of science as the promotion of man's welfare by the establishment of his domination over Nature. In the seventeenth and eighteenth centuries, particularly in the sixty or seventy years just before 1840, there were important, though tentative, technical scientific applications and the beginnings of mechanization in a few industries; but what Dr. Sherwood Taylor describes as the "precipitate arrival at maturity" of those applications and of that mechanization may truly be said to have occurred about the year 1840. To examine and to delineate these movements is the purpose of this book, and it is admirably accomplished.

In two chapters of the book progress during the hundred years in the spheres of health and of medicine is dealt with. These are entitled "The War Against Dirt" and "Modern Medicine and Public Health Services." There have been issued during recent years a number of publications, some of them quite excellent, covering this ground, or parts of this ground: but for comprehensiveness, accuracy, interest, and effectiveness, Dr. Taylor's chapters will compare favourably with any of them. In these two chapters there are only two words that we could wish away, and we hope the author may delete them in any future edition. On page 130 he writes: "The old methods of diagnosis by questioning the patient and using the senses of sight and touch, aided by a shrewd power of observation, have been steadily supplemented and supplanted." If the last two words are true this surely represents a retreat rather than a welcome advance and indicates one of the dangers of modern medical education and practice. These are by no means the only chapters of the book which have a direct medical interest or application. The others on transport and communications, on the conditions of labour, on the middle-class home, and on the opportunities and use of leisure, all contain points of importance for the practitioner. The last chapter is of a different character. It concerns the changes in belief and habits of thought. If it had been presented frankly as the individual "credo" of the author it would be worthy of the highest respect; and doubtless in one aspect

or another it approximates to the opinions of many to-day. It is not inaccurate, too, to describe thought in 1840 as "traditional" and in 1940 as "rationalistic"; but the chapter is incomplete and imperfect as a statement of the general belief of the people of Great Britain, which can still properly be described broadly as a Christian country.

PSYCHIATRIC ASSESSMENT

Personality and Mental Illness. An Essay in Psychiatric Diagnosis. By John Bowlby. With a Prefatory Note by the late Prof. Edward Mapother. (Pp. 280. 10s. 6d. net.) London: Kegan Paul, Trench, Trubner and Co., Ltd. 1940.

The central fact that this book seeks to establish is that in the absence of certain traits of character and temperament schizophrenia is unlikely to develop. Upon this observation the author bases a slightly polemical re-presentation of the now well-established psychiatric principle that psychiatric assessment should take into account not only the present symptoms but the previous personality of the patient, and he affirms a belief in Kretschmerian typology. He scouts the notion that there is any hard-and-fast or qualitative difference between psychoses and psychoneuroses; and curiously enough explicitly adopts the testimony of authors whose work tends to dispense with the statistical and heredity studies which probably alone could be decisive and who, unlike Dr. Bowlby, pay only lip-service to psychotherapy. Nevertheless, his work on pre-psychotic traits is interesting, although the numbers are too small to be conclusive and controls are lacking. On the self-preservative principle that those who live in glass houses should not throw stones, it would have been wiser if the arguments had been more irrefragable. For example, on the ground that certain traits are never found in personalities with affective disorders, he calls them specific schizoid traits, but takes little notice of the fact that three other traits are never found by him in schizophrenes. One of the marks of a sound theory is that it makes prediction possible, but when a potential schizophrenic, on his reckoning, fails to develop the disorder, the fact is relegated to a footnote. Nearly all the cases listed as "conversion hysterias" and "obsessional neuroses" would be considered to be constitutional depressions by most psychiatrists. Despite these faults, the thesis of the book is worthy of further attention.

THREE "PRACTITIONER" PUBLICATIONS

The "Practitioner Handbooks" continue to make their welcome appearance in attractively designed dust-jackets. *Modern Diagnosis,* edited by Sir Humphry Rolleston and Dr. Alan Moncrieff (Eyre and Spottiswoode (Publishers) Ltd., 12s. 6d. net), is a volume of 286 pages, and is based upon contributions to the *Practitioner* which have been made during the past few years. The article on technique of simple blood examinations and methods for collection of blood, by Dr. C. J. C. Britton, was especially written for the volume under review. The authors follow well-worn paths, and remind readers of much that they have learnt and forgotten, and also of what is new in the market-place. The life of a medical practitioner is one long revision course, and attempts such as this to help him are praiseworthy, but the price of the book seems to us rather high. From the same house comes yet another small volume devoted to surgery in wartime (*Special Surgery in War Time*: Eyre and Spottiswoode (Publishers) Ltd., 6s. net). Its seventy-four pages (unindexed) comprise articles on head injuries by Mr. D. W. C. Northfield; diagnosis and treatment of spinal cord injuries by Dr. Douglas McAlpine; abdominal injuries and wounds by Mr. V. Zachary Cope; chest injuries in modern warfare by Mr. T. Holmes Sellors; and the treatment of burns by Mr. A. B. Wallace. A third volume—which should be of much assistance to medical men—tells the reader what he must do to satisfy the demands of the modern inquisition—the Department of Inland Revenue (*Income Tax for Medical Practitioners*: Eyre and Spottiswoode (Publishers) Ltd., 6s. net). In 147 pages (including index) Mr. A. L. Boydon gives chapter and verse for the solution of all the many income-tax problems that beset a profession which has no great reputation for financial acumen. Some sections will attract more interest than others, and it is possible that many readers will skip the chapter on surtax and hurriedly go on to a later chapter—legal avoidance of tax. There is a misprint on page 30: 31/12/39 in the first column of Assumption 2 should be 31/12/38; and the final comparison of the result of applying the "cash" basis and the "profit and loss account" basis to the same case is misleading because no deduction for depreciation, or replacement, of car is claimed in the former alternative, although £41 is deducted in the "profit and loss" calculation.

Notes on Books

In *My Uncle Frank* Prof. THOMAS BODKIN gives an engaging account of his boyish recollections of Dr. MacMahon, a great character of a type of medical man now extinct. MacMahon was an Irish landed proprietor who did not enter upon the study of medicine until he was 40 years old. It is not surprising, therefore, that examinations presented difficulties. Once qualified, however, his human sympathies, his practical common sense, and his intimate knowledge of the people among whom he lived made him an invaluable asset to the whole neighbourhood, by whom he was greatly beloved. This little book is published at 5s. by Robert Hale, Ltd.

Experimental Physiology, by Dr. GEORGE H. BELL, is the practical classbook used in the Glasgow Medical School and is published in that city by John Smith and Son, Ltd., at 6s. The number of frog experiments is relatively small, and the author has shown great ingenuity in devising a long series of human experiments, most of which can be carried out with very simple apparatus. The course should give the medical student a wide basis of information regarding the manner in which his body functions.

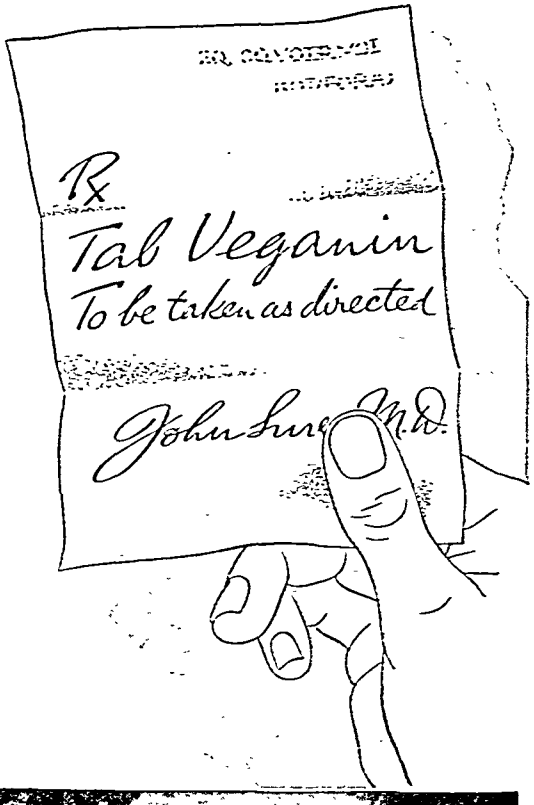
Preparations and Appliances

NON-ADHERENT GAUZE

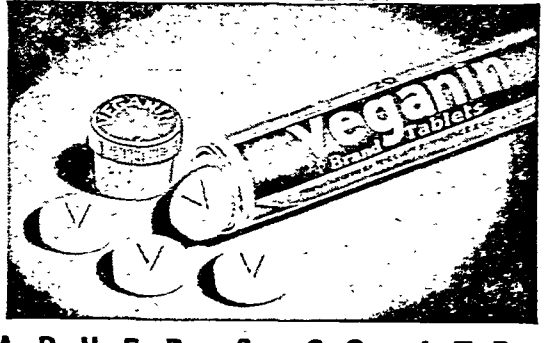
"Nonad Tulle" non-adherent gauze net (Allen and Hanburys Ltd.) consists of squares of wide-mesh gauze which are supplied embedded in a mixture containing 98 parts by weight of soft paraffin, and 1 part each of balsam of Peru and of halibut oil, the latter giving the material a specified vitamin A and D content. A single layer of this gauze is placed on wounds, burns, etc., and covered with dry dressings: it prevents adhesion to the wound surface but enables wound discharges to be absorbed by overlying dressings. The price of a box containing ten pieces 4 in. × 4 in. is 3s. 6d.

PYLUMBRIN (DIODONE)

Pylumbrin (diodone) is a British-made contrast agent manufactured by Messrs. Boots Drug Co., Ltd. It is used for excretion radiography of the renal pelvis, ureters, etc. The chemical name is "diethanolamine salt of 3:5-di-iodo-4-pyridone-N-acetic acid," and diodone is a non-proprietary title agreed upon for preparations of this compound. Pylumbrin has been submitted to extensive clinical trial and the results show that it is well tolerated and gives excellent contrast shadows.



With this prescription—



the Patient—

is assured of relief from pain and its nervous manifestations in a large number of conditions, ranging from simple headache to inoperable carcinoma, with the minimum danger of toxic action.

Veganin brand Tablets disintegrate speedily and are absorbed quickly. They are not habit-forming.

From all points of view, Veganin offers physicians an efficient and safe analgesic therapy.

WILLIAM R. WARNER & CO., LTD.
POWER ROAD CHISWICK LONDON, W. 4.

SOME OF THE PRODUCTS OF

GLAXO LABORATORIES

A PAGE FOR YOUR REFERENCE

PRODUCT	DESCRIPTION	FORM
ANTIVIRIN *Antivirus preparations*	Prepared in jelly and liquid forms from cultures of streptococcus, staphylococcus and other organisms. The jelly is for use from the tube in easily accessible infections; the liquid for irrigation of deeper-seated lesions. In the treatment of boils, sinuses, abscesses, carbuncles, running ear, infected wounds, etc., when direct contact between the lesion and the corresponding virus is obtainable, antivirus therapy is dramatically effective.	*The jellies in long-nozzle or collapsible tubes, the liquid in 20 cc. bottles.*
FLAVOGEL *Acriflavine Jelly*	Flavogel presents acriflavine (1 in 1,000) in a water-soluble jelly base, smooth and soothing in action. Intimate contact between wound and tissue is achieved, with maximum bactericidal effect. For use on all wounds, whether infected or not. Flavogel does not cause pain, and minimises tendency of dressing to stick to the wound.	*1½ oz. tubes, 16 oz. jars.*
GLUCODIN *The reinforced Glucose*	GlucoDin, the original preparation of glucose, vitamin D and calcium glycerophosphate, has long been successful for the prevention and treatment of ketogenic disorders such as travel-sickness and fat-intolerance, and for providing immediate energy without taxing the digestion. GlucoDin replenishes glycogen reserves, supplies the carbohydrate essential to fat metabolism and helps to normalise calcium and phosphorus metabolism.	*1 lb., 3 lb. and 7 lb. tins.*
LEVU-CALCIN *Calcium Levulinate*	A sterile aqueous solution of calcium levulinate for parenteral use in all conditions needing urgent calcium therapy. The solution is stable. It has been used with marked success in pre- and post-operative treatment for preventing haemorrhage; inflammatory and allergic conditions with exudation; and hepatic insufficiency. For intra-venous or intra-muscular injection.	*Boxes of 3 x 10 cc. (10%) 6 x 2 cc. (15%)*
MINADEX *Mineral Vitamin Tonic*	An enjoyable reconstructive tonic, composed of three groups of therapeutic agents. Each fluid ounce contains: Ferr. et Ammon. Cit. Vir. 13½ gr.; Mang. Glycerophosph. 1/25 gr.; Cupr. Sulph. 1/25 gr. Calc. Glycerophosph. 2 gr.; Pot. Glycerophosph. 1/5 gr.; Sod. Glycerophosph. 1/10 gr.; Vitamin A, 18,000 i.u.; Vitamin D, 3,000 i.u.	*6 oz. and 12 oz. bottles, and 80 oz. winchesters.*
OSTERMILK *Successful Infant Food*	The successful dried milk food. The proportions of protein, carbohydrate and fat are carefully adjusted and standardised. The curd is light; extra vitamin D is added in stated quantity; the added iron content is three times that of milk. Ostermilk No. 1 is modified for the first three months. No. 2 full-cream is for the later months.	*16 oz. tins.*
SOLANTOIN *Anti-convulsant*	For the treatment of severe, inveterate, unresponsive epilepsy. Solantoin is the Glaxo preparation of the anti-convulsant sodium diphenylhydantoinate. Non-depressant. To be given alone or with a nightly dose of the usual anti-convulsant. Dose is one to three 0.1 gram tablets daily.	*Bottles of 25, 100 and 500.*
G.L. AMPOULES	The range of potent drugs available in G.L. ampoules covers a wide field. The ampoules have several advantages. They open quickly, cleanly and without splintering. A wide, smooth mouth is left for the entry of the syringe needle, and the ampoule stands firmly on its base. The prices are considerably below those usually prevailing.	*Full list available on request.*

THE MECHANISM OF INFLAMMATION

The sequence of events in an area of inflammation has been described in almost unvarying terms since the days of Cohnheim and Metchnikoff, and it would occur only to the more questioning mind that there may be much yet undiscovered about it. That a whole series of new explanations could be found for the successive stages of the inflammatory process is a development which few people can have expected. Yet this is the outcome of studies which have now been pursued for over ten years by Valy Menkin of Harvard, and anyone who has to write or teach on this subject or to investigate it experimentally from whatever standpoint must take account of his findings and conclusions. They are now conveniently assembled in a book recently published,[1] in which the whole argument is logically set out. Many experimental details upon which the validity of his conclusions may well depend are only to be found in the author's numerous original papers.

The first stage of inflammation is the subject of Menkin's most extensive advances beyond existing knowledge. These consist in showing that in areas of inflammation a hitherto unknown substance is produced which is responsible both for increased capillary permeability and for leucocytic emigration. This substance, which has been named "leukotaxine," can be extracted from inflammatory exudates and purified by a complex process which eventually yields the substance in crystalline form. Since the digestion of serum with trypsin yields a product with identical characters, leukotaxine is considered to be formed by the breakdown of body proteins. It is decidedly not histamine, from which it differs in seven carefully studied properties. Although leukotaxine is locally chemotactic for leucocytes, it does not cause leucocytosis, but inflammatory exudates contain another substance which has this effect: this differs both from leukotaxine in its physical properties and from nucleic acid in the rapidity of its action; hence it would appear to be another product the existence of which has hitherto been unknown. A second very important item in Menkin's redefinition of the inflammatory process is the fibrin barrier. The deposition of fibrin both in tissue spaces and in lymphatics, which walls off the inflamed area and localizes the infection, is considered to be "the primary and basic mechanism of fixation." Its existence is proved in a variety of ways apart from direct demonstration in histological sections: dyes, insoluble particles, and foreign proteins, either injected into the area or reaching it from the blood stream, are found to be retained there. Among other effects this fixation of the elements concerned in the inflammatory process is said to lead to an increased local concentration of antibodies. Strangely enough, although staphylococcal infections become walled off by fibrin in as short a time as one hour, whereas streptococcal lesions may drain freely for as long as forty-five hours, it is not considered that either staphylocoagulase on the one hand or streptococcal fibrinolysin on the other has anything to do with this striking difference. The third major proposition in Menkin's thesis is that the cytology of an inflammatory exudate varies with and depends on its *p*H. With the increasing acidity due to a local accumulation of lactic acid, polynuclears die and are replaced by macrophages, which are not only attracted by but are capable of activity in the more acid medium. These are the three main pillars in what is almost a totally new edifice of theory about the inflammatory process.

Not all these conclusions, or even the observational facts on which they are based, will be unquestioningly accepted—indeed, some have already been contested. That the whole hypothesis is highly mechanistic, whereas some of the alternatives are teleological, is in its favour, but Menkin claims to have demonstrated so many new sequences of cause and effect that he seems almost to have devised experiments with the object of adding to their number. Some of his experiments involve highly artificial conditions: the isolation of leukotaxine, for instance, is a very complex process, although the fact that non-inflammatory fluids do not yield this substance from it is an answer to such criticism. Perhaps the most formidable objection to accepting leukotaxine as the cause of exudation is the fact that capillary permeability may be increased within two minutes of the application of an irritant: is it conceivable that the protein katabolism necessary to produce leukotaxine can complete itself within so short a time? Most of the facts about fixation in an inflamed area appear unassailable, but the observations of J. P. Fox[2] on the concentration of antibodies in inflamed areas are far from convincing; such differences as he found are explicable merely by increased vascularity, and these form the main basis of Menkin's assertion on this point. The proposition that the cytology of an exudate is controlled by its *p*H has been hotly contested by B. Steinberg and A. Dietz,[3] who used different methods of studying this point; it may be added that the general behaviour of macrophages in different kinds of infection, not forgetting their preponderating part in conditions never accompanied by suppuration, does not encourage the idea that acid peculiarly attracts them. Although this may seem to be only playing with words, bacteriologists will have something to say about Menkin's definition and explanation of "invasiveness." *Streptococcus pyogenes* is said to be invasive because it produces little local injury and hence does not stimulate the formation of a fibrin barrier, whereas *Staphylococcus aureus* is rapidly walled off owing to the intensity of the local injury produced. This seems too complete a paradox to contain the whole of the truth. It also needs to be explained what is the real relation between invasiveness and the "spreading factor" of Duran-Reynals; Menkin is inclined to regard them as connected, but it has repeatedly been shown that staphylococci form this substance, a fact with which the rapid

[1] *Dynamics of Inflammation*, by Valy Menkin. New York: The Macmillan Company, 1940.

[2] *J. Immunol.*, 1935, 31, 293.

[3] *Arch. Pathol.*, 1938, 25, 777.

walling-off of staphylococcal lesions seems inconsistent. The concept of localization by a purely mechanical barrier disregards the function of agglutinin, although Menkin grants the localizing effect of this antibody in the immune animal. These are some of the difficulties in the way of accepting all these new propositions as they stand; but however it may come to be regarded in the light of further work, Menkin's study of inflammation represents an exceptional effort to get back to first principles, and should reawaken interest in simple and fundamental questions of cellular behaviour. If there is any truth in his contentions at all we must admit that years of hackneyed repetition have convinced us of comprehension when in fact much was still hidden from us.

PROGRESS IN ELECTRO-ENCEPHALOGRAPHY

A recent contribution from Berlin on human electro-encephalography illustrates the skill of some German scientists in using a long-winded fallacy to make a mystery out of a matter of fact. Kornmüller,[1] for example, assumes that the lobe of the ear is an "indifferent" or reference electrode for the brain. Actually, the ear is in as good anatomical and electrical contact with the brain as any part of the skull; a recording system connected between the ear and another point on the head is as likely to pick up electrical phenomena from the one electrode as from the other. In fact, some of Kornmüller's own records illustrate this clearly. Secondly, he assumes that the size of the deflections in his records depends upon the degree of amplification to which he has set his apparatus, neglecting the fundamental derivation from Ohm's law that the size of the potentials across any pair of electrodes is proportional not only to the electromotive force concerned but also to the resistance between the electrodes. In common speech, if the electrodes are very close together they will tend to be short-circuited and will pick up relatively little of the available voltage. These are both ancient fallacies long ago exposed and acknowledged, yet when wrapped up in a twenty-one-page paper with ten illustrations they encourage Kornmüller to develop an abstruse and illogical theory of the electro-anatomical structure of the brain. In an entirely different class is work recently published in America. Schwartz and Kerr[2] have studied the electrical activity of the brains of twenty-two patients by placing sterile electrodes directly on the cortex during operations. This is a method of investigation used previously only by Foerster and Altenburger in Germany and by Walter in this country. The American workers report much the same findings as the earlier observers. In "normal" cases the rhythms are much the same as those seen with electrodes on the scalp, though of course they are very much larger. In cases of cerebral tumour it is confirmed that the new tissue has no electrical activity at all, whereas the cortex in the neighbourhood is discharging enormous slow waves, the "delta" waves first used by Walter to localize intracranial lesions. When the whole cortex is disturbed, as in hydrocephalus, the direct leads pick up less than the scalp ones, since they are so close together that the large diffuse swings affect both equally.

These observations provide useful objective confirmation of the discoveries made in the last few years in the course of clinical or applied electro-encephalography; this, too, has progressed in technique and trustworthiness. The use of the direct recording ink-writing oscillograph lessens the work of the operator, since indefinitely long records can be taken and no time need be spent in the dark-room deciding whether further exposures are necessary. This means that less time is needed to take a good electro-encephalogram than to take a good *x*-ray picture; if necessary, head injury cases, for example, could be put through at the rate of ten an hour. Regarding the accuracy of the method in cases of cerebral tumour, a report from the Mayo Clinic[3] states that electro-encephalography alone is more trustworthy than clinical examination or air replacement alone (86% accurate as against 81% and 82% respectively). Moreover, in some instances the electro-encephalogram gave the location of the tumour where other methods had failed entirely. This amply confirms Walter's original claim of about 80% accuracy based on several hundred cases, including posterior fossa lesions, which Smith, C. W. P. Walter, and Laidlaw[4] have found to produce definite though less specific changes in the electro-encephalogram. In cerebellar cases the effect may be an indirect one on the occipital cortex by pressure through the tentorium: the signs are much more distinct in children than in adult patients.

These observations show quite clearly that in diagnosing intracranial lesions a very close approach can be made to 100% accuracy without unduly disturbing the patient, provided that all the available methods are used together. Where neurological examination fails—in tumours of the "silent" areas—the electro-encephalogram steps in, and, where the lesion is too deep or too widespread for either, air replacement can be resorted to. There is no reason why every patient should not be given the best chance which well-directed surgery can offer, and the black outlook for intracranial lesions, including injuries, may be lightened not a little by full use of modern methods.

ADRENAL SEX HORMONES

The practical results of recent researches into the hormones of the ovaries, testes, and adrenals are now becoming widely known through the resultant easy availability of oestrogens, androgens, and corticosterone for therapeutic use. But progress in these fields has brought just as much complication as it has simplification. In the early days of the oestrogenic and androgenic hormones there was a natural tendency to assume that the former were characteristically present in women, the latter in men. But it soon became clear that this was not so, for androgenic or masculinizing hormones were found to be excreted by all normal women as well as by men, and the female oestrogenic hormones by men as well as women. From the point of view of hormone excretion the difference between the sexes is quantitative rather than qualitative, males tending to excrete more androgen than oestrogen and females the reverse. It seemed therefore that the gonads of each sex were capable of producing

[3] *Proc. Mayo Clin.*, 1940, **15**, 147.
[4] *Arch. Neurol. Psychiat.*, Chicago, 1940, **43**, 472.

the hormones of both, only the proportions being varied. Fresh complications appeared with the discovery that castrated men frequently continue to excrete sex hormones in the urine, as also do women after oophorectomy. Clearly some independent source of these hormones must be present in the body. There were already good reasons for suspecting the adrenal gland. These hormones all belong to the chemical group of sterols, and the cortex of the adrenal is known to be rich in such sterols. In the rare condition of adrenal cortical tumour the female develops a pronounced degree of masculinization with lowering of the voice, enlargement of the clitoris, and excessive body hair of male distribution. Sufferers from this condition show a relatively enormous excretion of androgenic substances in the urine, and the output of oestrogens may also be very high even in men. Furthermore, among the many substances which have been extracted from the cortex of the adrenal are several of the so-called sex hormones, including progesterone, oestrone, and androgens. These facts all suggested that the adrenal is intimately concerned with sex-hormone production. Callow, Callow, and Emmens[1] have recently been investigating the subject. In a group of eleven eunuchs they found androgen excretion in the urine to be within normal male limits in all, though the average for the group was a little lower than that to be expected in a group of normal males. Similarly in a group of eighteen women who had had their ovaries removed androgen excretion was normal in twelve, though oestrogen output was low in nearly all. It was clearly not possible to investigate sex-hormone excretion in adrenalectomized men, since the operation, even if it were attempted, is incompatible with continued life. The nearest attainable state to it is Addison's disease, and Callow, Callow, and Emmens have therefore studied this. In a series of seven cases they found androgen excretion reduced in only one. Though the extent of the adrenal damage in their cases is unknown, their results do not suggest that androgens are formed solely by the adrenal gland. These authors incline to the view that both adrenals and gonads contribute to sex-hormone production, the adrenals being the major contributor of androgens, the ovary of oestrogens. It is becoming evident, therefore, that the adrenal cortex, besides being essential to life, plays a much more important part in the physiology of sex than was suspected a few years ago.

EPILEPSY

Essential epilepsy remains a mystery, though it is progressively less a mystery than it was. The electroencephalograph is the latest method by which the problem has been illuminated, and Lennox has gone so far as to suggest that epilepsy should be called "cerebral dysrhythmia." But this explosive dysrhythmia is itself an expression of something that still eludes us. The type of rhythm which is characteristic of epilepsy is that which is associated with a localized absence of normal cortical activity. It is therefore the more interesting that sodium diphenyl hydantoinate is found to have an effect on the convulsions themselves without evidently depressing the brain as a whole, as both luminal and bromide do.[2] This suggests that, whereas the effects of the latter depend on inhibition of the spread of the excitatory process, the effects of sodium diphenyl hydantoinate may be on the excitatory process itself at its origin. It has been recorded that patients receiving sodium diphenyl hydantoinate are mentally brighter, and that the effect is reinforced by benzedrine. It is not inconceivable that the new drug works by stimulating the cortex to supply the activity that is lacking to inhibit the "idling rhythm" of epilepsy. This problem does not appear to be answered yet by the work on sodium diphenyl hydantoinate, the literature of which is summarized by Blair.[3] That sodium diphenyl hydantoinate is therapeutically useful seems very likely after making allowance for the never-failing optimism of early reports of results with any new remedy. Sodium diphenyl hydantoinate is found to be capable of reducing still further the incidence of attacks in patients who have been benefited up to a point by bromide or luminal; and, conversely, some cases appear to do better on the latter than on sodium diphenyl hydantoinate. It is said to have no influence on the mental symptoms of epilepsy. The principal disadvantage is the occurrence of toxic symptoms, chiefly of a mental and dermatological kind. At least it can be said that a new effective symptomatic agent has been discovered. It is also worth noting the method by which its efficacy was hit upon. Convulsions were induced in an intact animal by passing an electrical current through the skull, and various drugs were administered to discover which had the greatest anti-convulsant effect. Methodical investigation *in vivo* of this kind, tedious as it may appear, has thus had another success, in a way reminiscent of Foster Kennedy's discovery of the utility of quinine in myotonia. Such researches are painstaking rather than brilliant, but their systematic nature is worthy of commendation; while the possibility of using the intact animal must be welcome to the researcher in pharmacology who wishes, as he must do, to be able to apply the lesson he learns to the clinical field—that is, to the intact human animal—with as much accuracy as he can achieve.

THE MECHANISM OF HEADACHE

Though recognized as one of the commonest symptoms of many grave as well as of several trivial disorders, headache has until lately attracted little attention from the point of view of causation. This state of affairs is attributable to two causes: first, dearth of suitable methods of study, and, secondly, the inertia that from time to time clogs certain aspects of human thought and endeavour—for some of the most fruitful of recent observations have been largely amplifications of those first made by Lennander[4] in 1906 on the sensibility of the cranial cavity. The most recent contribution on this subject is by Ray and Wolff,[5] who have explored exhaustively the sensibility of intracranial and extracranial structures in thirty patients during operations under local anaesthesia: all these patients were co-operative and in a fit state to answer questions intelligently. Of extracranial structures, galea, fascia, muscle, and arteries, and to a less extent the veins, give rise to pain when stimulated in varying ways; the pain is in each instance fairly well localized to the point of stimulation. The periosteum is likewise sensitive to pain, but the substance of the cranial bones is not. The parietal dura is insensitive over the calvarium except along the course of the meningeal arteries and their main branches and the superior longitudinal sinus; the dura over the base of the skull is generally sensitive in the anterior and posterior fossae, though not in the middle fossa. The falx is insensitive to direct stimulation except near the sagittal and superior longitudinal sinuses, but pain is produced by its deflection to one or other side. Pressure on the upper surface of the tentorium cerebelli produces pain behind the ipsilateral eye, but the under surface is less sensitive.

[1] *J. Endocrinol.*, 1940, 2, 38
[2] *Psychiat. Quart.*, 1940, 14, 595, 603, 612.
[3] *J. ment. Sci.*, 1940, 86, 518.
[4] *Mitt. Grenzgeb. Med. Chir.*, 1906, 15, 465.
[5] *Arch. Surg.*, Chicago, 1940, 41, 813.

The pia arachnoid, the substance of the brain, the ependymal lining of the ventricles, and the choroid plexuses are insensitive, but the internal carotid, vertebral, and basilar arteries are sensitive, as are their anterior and middle cerebral, pontine, and posterior inferior cerebellar branches in the proximal few centimetres of their course. Inflation or deflation of a lateral ventricle causes pain probably by traction on the dural sinuses by the insensitive cerebral veins which join them. Inflation of the third ventricle causes pain which is relieved by deflation and which is attributed to traction on the adjacent arteries at the base of the brain. From these observations Ray and Wolff suggest that the headache of cerebral tumour is probably due to traction on the dural sinuses and the arteries at the base of the brain, as is the lumbar puncture headache, and that other headaches arise from dilatation of intra- and extra-cranial arteries. Their observations and conclusions are in general harmony with the suggestion made by Pickering[6] from his observations on the behaviour of different kinds of headache to simple forms of experimental procedure. It is to be noted that no evidence was found to support the idea that headache is often due to raised intracranial pressure. This theory dies hard. It is one which has been so easy to put forward and so attractive for the uncritical to accept that for many years it has held the field without any attempt at verification. But now that all the known facts about headache can be explained without its aid, perhaps it may be abandoned by serious students of the subject. Finally, it is to be pointed out that these new observations emphasize that there is no one cause of headache; many structures may give rise to the pain and they may be stimulated in a variety of ways.

ACTION OF TYPE-SPECIFIC ANTIBODY ON THE PNEUMOCOCCUS

The effectiveness of type-specific serum in the treatment of pneumococcal pneumonia is well established, but the action of the serum on the pneumococcus and on the pulmonary lesion is by no means clearly understood. It has been suggested by a number of observers, including Kline and Winternitz,[7] Wang and Van Allen,[8] and Fox,[9] that anti-pneumococcal immune bodies could not penetrate into the pneumonic lesions produced experimentally in rats. The problem has been reinvestigated by Kempf and Nungester,[10] who, using horse and rabbit antiserum, were unable to demonstrate antibody in the lungs after intravenous injection. They therefore concluded that it was unlikely that antibody could accumulate in the consolidated areas of the lung in sufficient concentration to neutralize the specific polysaccharide present in the alveoli. Nye and Harris,[11] studying human material at necropsy, reached the same conclusion. Opposite results have, however, been obtained by Barry Wood.[12] Experimental lobar pneumonia was produced in white rats by inoculation of encapsulated Type I pneumococci suspended in mucin, the subsequent pneumonia being invariably fatal within five days. The most striking feature of the process of spread was the presence at the advancing margin of what has been termed "the oedema zone" (Robertson *et al.*[13] and Gunn and Nungester[14]). The pneumococci were most numerous in this region, and histological examination of the lungs at intervals of from twelve to thirty-six hours after inoculation showed that the pneumococci spread into normal alveoli principally by way of the oedema zone. The action of type-specific antibody upon the advancing lesion was observed in rats treated from two to eighteen hours after inoculation with pneumococci. At first 6,000 units, contained in 1 c.cm. of concentrated anti-pneumococcal rabbit serum, were injected intravenously, but later it was found that the same result could be obtained with as little as 120 units. Six to eight hours after treatment the margin of the consolidated area had become sharply demarcated, in striking contrast to the irregular haemorrhagic border characteristic of an advancing lesion. Microscopically there was pronounced agglutination of the pneumococci, particularly in the oedema zone, within an hour of treatment, while organisms with swollen capsules were frequently noted. Following the agglutination and swelling of the pneumococci invasion by new alveoli ceased, phagocytosis by polymorphonuclear leucocytes began within six hours, and few, if any, organisms could be found either extracellularly or intracellularly within ninety-six hours of the beginning of treatment. The macrophage reaction became prominent in four days, and at the end of one week extensive clearing of the exudate was noted. It is therefore believed that type-specific immune bodies actually enter consolidated pneumonic areas in the lungs.

HISTAMINASE

Much evidence, as yet hypothetical, suggests that the liberation of histamine or a histamine-like substance in the tissues at the site of an antigen–antibody reaction is the immediate cause of anaphylactic symptoms. Destruction of histamine in the body may in part be brought about by an enzyme called histaminase, found in relatively large amounts in the kidneys and in the wall of the large and small intestine, and in moderate amounts in many other organs.[1] Diamineoxydase[2]—to give it its chemical name—has been prepared commercially (torantil) from the above sources, generally hog's kidney, and has been recommended in the treatment of allergic conditions. It is given orally in enteric-coated tablets and also intramuscularly; each tablet or ampoule is said to be capable of detoxicating a certain number of histamine units. Most communications on the subject deal with its use in allergic dermatoses and in cases of cold allergy. Laymon and Cumming[3] obtained some benefit in cases of urticaria, but they question its value in general. Miller and Piness[4] gave histaminase to twenty-nine patients with urticaria, five with dermatitis, five with asthma, and three with hay-fever. They found that the enzyme failed to give unequivocal evidence that it was in any way responsible for relief or prevention of any of the patients' symptoms, nor did it prevent urticaria after the administration of a pollen or epidermal allergen. Goldberg[5] found it useful in alleviating pruritus, especially in chronic urticaria and when injected. It was first successfully given in cases of cold allergy by Roth and Horton,[6] but Baker[7] in two similar cases used in addition gradual desensitization to cold by immersion of the hands in cold water. Kile and Rusk[8] report a case of cold urticaria in which histaminase was tried without success. Foshay and Hagebusch[9] found that it alleviated the pruritus of serum

sickness, while Roth and Rynearson used it with success in allergic reactions to insulin.[14] Keeney[15] administered it orally to fifteen sufferers from ragweed hay-fever with no effect. It is thus obvious that there is no clear-cut case for histaminase having any beneficial therapeutic effect in allergic diseases, except perhaps in cases of chronic urticaria, but as in this condition long and irregular intermission of symptoms is by no means uncommon any true beneficial result is hard to estimate. These findings are in accord with a recent note by Best and McHenry[16] who draw attention to the fact that when they summarized the work on histaminase in 1931 they pointed out that the presence of the enzyme in various tissues may constitute one of several defence mechanisms of the body for the inactivation of histamine. No suggestion was made that its administration might be a useful form of treatment. In fact, laboratory investigations showed that (1) histamine administered to animals over several weeks or in a single large dose had no effect on the histaminase content of the kidneys; (2) histaminase is inactivated by pepsin in acid solution and trypsin in slightly alkaline solution, so if given orally it is unlikely to survive the action of the proteolytic enzymes of the gastro-intestinal tract; and (3) the intravenous or intramuscular administration of histaminase failed to have any effect upon histamine present in the body or on that given by injection, even using preparations four times as potent as any commercially available.

HEALTH IN ICELAND

Perhaps few countries struggle against greater natural handicaps than Iceland. This remote island in the far north, with its severe climate and poor soil, can, however, show a record of health progress which does great credit to the inhabitants. Almost until the end of last century the child death rate was very high, and epidemics of such diseases as measles, influenza, and whooping-cough were rife. Towards the end of the century, however, a general revival of interest in both secular and spiritual matters brought with it a campaign to improve the health of the people. In the last fifty years the population has increased by about 70%. The Government has taken an active part in health measures, and has built up a comprehensive sanitary code. From being a short and stunted people the Icelanders have now become the tallest of all the Scandinavians, and their resistance to disease has increased considerably. The endemic conditions of leprosy, hydatid disease, and tetanus in young children, for which the island was once notorious, have nearly disappeared. Typhoid has not been completely exterminated, but its end is in sight. Diphtheria, formerly a plague among children, has done little damage since serum treatment and immunization were introduced. The death rate among children is now one of the lowest in the world. Rheumatic fever is rare. Since 1918 influenza has been epidemic for about three months in every other year: in the intervening years the population seem to be almost immune. The most important disease from the public health point of view is tuberculosis: this has made its way over the country like a protracted and difficult epidemic, which all the efforts of the authorities have been unable to check. Since 1933, however, a steady diminution in the incidence of tuberculosis has been recorded. Gonorrhoea is endemic in the towns, but syphilis is very rare and in most cases the infection is imported; soft chancre is unknown. The islanders seem to observe a somewhat large sexual freedom, for the figure for illegitimate children is about 20%; on the other hand, prostitution hardly exists at all. The incidence of certifiable insanity is rather high—3.5 per 1,000—especially as there is next to no post-syphilitic lunacy; the commonest form is manic-depressive insanity. Mental deficiency affects 2 per 1,000 of the population. In spite of rigid control of the consumption of alcohol by the State, it is being increasingly drunk, and causes anxiety to the health authorities. In his recent survey of the health conditions of the island,[1] Dr. Vilmundur Jonsson says that much remains to be done, but that the general standard of fitness may be expected to increase. Greater interest is being taken in sport and mountaineering, more fresh food and vegetables are being consumed, the islanders are drinking more milk, and an interest in health and its maintenance is becoming general. He sees no reason why, if the Icelanders retain political independence and financial stability, the nation should not become permanently one of the healthiest in the world.

ANTI-ALOPECIA FACTOR

Woolley[2] has shown that when young mice were fed on a diet consisting of sucrose, purified casein, salts, cod-liver oil, corn oil, yeast extract, thiamine (aneurin), riboflavin, vitamin B_6, nicotinic acid, pantothenic acid, choline, and *p*-alanine, they ceased to grow after five to six weeks, and quite suddenly all the hair except that on the head, tail, and occasionally the legs fell out. The denuded area gradually became scaly and red, and sores soon developed. Aqueous liver extract restored the mice to normal in three to seven days. The most active part of the extract was that insoluble in 70% alcohol. This fraction did not promote the growth of rats, lacking only the "filtrate factor," which indicates that the "filtrate factor" contains at least two substances—one necessary for the growth of the rat, and one for preventing alopecia in mice. The active substance was not easily adsorbed on norite, nor was it dialysable until treated with barium hydroxide and lead acetate. It is not biotin, nor *p*-aminobenzoic acid. The ether extract of the alcohol-soluble portion of liver extract was inactive: therefore the alopecia factor is not the anti-grey-hair factor. Recent work indicated that the factor might be a phosphoric ester of inositol, and cereal grains known to be good sources of this compound were found to be good sources of the alopecia factor. Phytin, inositol phosphoric acid, and also inositol itself were therefore tested and found to be very potent, the dose of either required to cure severe cases being about 100 mg. per 100 grammes of ration. When the non-dialysable alcohol-insoluble portion of the liver extract was autoclaved with alkali, crystals were obtained which had a melting-point of 214–216° and a carbon content of 39.8%. Inositol obtained from a different source had a melting-point of 215–216°. Thus it seems that in the mouse inositol or some derivative of it acts as an anti-alopecia factor.

The medical profession of this country has heard with deep regret the announcement that Sir Frederick Grant Banting, F.R.S., F.R.C.P., Hon. F.R.C.S., joint discoverer of insulin, and since 1923 Professor of Medical Research in the University of Toronto, has been killed in an aeroplane crash in Trinity Bay, Newfoundland. The flight on which he and two companions lost their lives was made in connexion with Sir Frederick's research work for the war effort.

THE EMERGENCY MEDICAL SERVICE AND THE FUTURE*

BY

JOHN B. HUNTER, *M.C.*, M.Ch., F.R.C.S.

Surgeon, King's College Hospital; Group Officer, E.M.S.

I shall not tax your memory to any great extent, but ask you to return to a very recent time—September, 1938—Munich.

The threatening clouds disappeared and we for a time relaxed, but the memory of those days had left a bitter taste in the mouth, and the medical profession stirred uneasily at the thought of what might have been, and what perhaps was to come. As the months passed no signs could be seen of any attempt to deal with the casualty problem on the part of those in authority. Early in 1939 a meeting of representatives of the staff of the London teaching hospitals was arranged under the title of the Hospitals War Committee. It was decided then to ask the Voluntary Hospitals Committee to combine and meet the Ministry of Health to hear what arrangements were being made in connexion with the medical services if war should break out. As a result of deliberation the Ministry put forward tentatively its Sector scheme whereby twelve members, one from each of the teaching hospitals, should be selected to advise the Ministry on hospital arrangements in the London area in the event of war, and link the teaching hospitals to its casualty scheme.

Planning the E.M.S.

As soon as contact was made with the Ministry it became clear that much work had already been done in relation to dealing with the problem, not in detail but in rough outline. England had been divided into Regions, each independent of the others, so that districts would be able to carry on the functions of life if cut off from the rest of the country; each had its own Commissioner with staffs superintending all services, and, among others, a Hospital Officer to deal with the medical problems. London alone presented a special problem on account of its size and vulnerability from the air, further complicated by the fact that it had so many hospital beds in proportion to those in the Home Counties. A rough census of the beds available, and buildings suitable for use as hospitals, outside London had been made, and although in the majority of instances these numbers were optimistic they formed a foundation on which it was possible to work. Such were the beginnings of a Service.

The Ministry of Health was relying on its Hospital Officers to co-ordinate the arrangements in each region, making use of the County Medical Officers of Health as its agents. The introduction of the Sector system in the London Region complicated the picture, and very naturally the M.O.H.s must have questioned the appearance of these strange creatures, the Group Officers, in their pond, but their good will overcame many difficulties and misunderstandings. As time went on, and especially after the outbreak of war, their assistance and knowledge were placed freely at the disposal of the Group Officers and went very far to make the Emergency Medical Service.

In those months before the war there was a great deal of work to be done: the buildings, institutions, and hospitals outside London that had already been earmarked were visited; and, together with the committees or local authorities in charge, arrangements were made, and schemes drawn up, for their expansion in case of war. Many difficulties were encountered by reason of the fact that these buildings were carrying on their peacetime function, and considerable dislocation of those functions would have taken place if the alterations planned had been put into being before war broke out. In consequence such matters as new theatres, *x*-ray departments, and nursing-staff accommodation remained paper schemes, and with few exceptions were not started before the war. The result was that in September, 1939, when these hospitals were required, staff quarters were short or uncomfortable, and essential services were inadequate. It is difficult to know how this could have been altered, unless the hospitals had been put on a war footing six months or more before war broke out, and remembering the temper of the Government and the people at that time it was not practical politics.

During this period the Group Officers met once a week in London (with officials from the Ministry) and the minutes of those meetings are interesting reading. The whole range of an emergency service was explored, and agreements were come to on every possible point that might arise in connexion with such a scheme. Very early in the discussions it was clear that the number of beds provided would be inadequate if the astronomical figure of casualties given by experts was to be taken as a guide. Those figures we know now, for a variety of reasons, were fortunately too high, but they were figures for which we had to legislate. Existing beds in provisional hospitals were inadequate, and the Ministry decided to put up hutted hospitals, using in most instances the administrative services of existing hospitals or institutions. This was work that did not have to wait, but could be put in hand at once without causing dislocation of existing services. Any delay in the building of such huts was due to administrative difficulties very real in peacetime, but not so readily understood in our present mood. These huts were not ready until after war had broken out, and a second expansion of hutted hospitals was seriously interfered with by difficulties in obtaining suitable material. Arrangements were also made for certain groups of beds, or individual buildings, to be reserved as special centres or hospitals.

The beds provided have been more than adequate for the requirements of the casualty service, but it is fortunate that so many beds were provided, because in the sequel the calls on the E.M.S. were very diverse, and the excess of beds allowed for an expansion in its services—services that were not envisaged in the original scheme.

Equipment and Staff

Other major problems were those of medical supplies and equipment, and the chief of these were surgical instruments and *x*-ray apparatus. As regards the first, lists were prepared and, with the assistance of the Consultant Advisers, approved. The instruments to be provided were for a casualty service, and no attempt was made to provide the more elaborate surgical equipment that is required for civil practice. It must be remembered that for years past surgeons had been using nothing but hand-forged instruments. Hence the surgical instrument makers of the country were unable to provide suddenly large quantities of mass-produced instruments, and considerable difficulties were encountered in obtaining the enormous quantities needed for the E.M.S. at the same time that the requirements, always large, of an expeditionary force had to be met.

The second—the *x*-ray problem—was even more difficult. It became evident early in our discussions that *x*-ray apparatus was very short of requirements for the expanded number of beds, and that it was an essential of any casualty service. It was decided that most hospitals would have to be served with portable machines, as it was not thought possible that fixed machines could be moved out of London in time, even if the necessary technicians for dismantling and reassembling the machines were available. This decision was come to because it was supposed that on the outbreak of war London, being an obvious target, would be bombed at once. In the sequel this was not so, and readjustments had to be made to house fixed sets which became available, not only from manufacture in this country but also from America. By the generosity and patriotism of the voluntary hospitals large amounts of equipment were made available, especially from the London hospitals. There can be no doubt that this equipment made it possible for many emergency hospitals to function on the outbreak of war. Transport also came under review, and here it

* Presidential address (abridged) given to the Section of Surgery of the Royal Society of Medicine, February 5, 1941.

was found that arrangements were already under way not only for transporting casualties from the scene of the incident but also for interhospital evacuation, and this plan is the one in operation to-day.

During the whole of the discussions the question of staffing the emergency hospitals was constantly reviewed: this fell into three categories—medical staff, nursing staff, and lay staff. The lay staff formed two groups: expert lay staff, such as theatre porters and technicians, and ordinary domestic staff and porters; the first clearly had to be provided from the voluntary hospitals, the second was the concern of the local authorities owning the hospitals. Nursing staff was a large problem, and it was quite clear that the staffing of the increased beds would not be done on a peacetime basis, and that even on a reduced scale there would be considerable shortage, as has proved to be the case. In order to help with this problem Sector Matrons were appointed, and a pool of nurses from the various hospitals was made, including the L.C.C. hospitals in London. These nurses were allocated to the emergency hospitals, together with members of the Civil Nursing Reserve, a new body which was to be enrolled as a war-time measure. Outside London the arrangements for nursing were in the hands of the Regional Hospital Officers and the County Medical Officers of Health.

The medical staff requirements were not so easily arranged on paper. Requirements for each hospital differed according to their position geographically and the type of work that was likely to be undertaken. A rule-of-thumb method could be employed for the house-officer type, but not for more senior grades. Every department of medicine had to be catered for in one hospital or another, and an attempt made to co-ordinate the services of each department, without overlapping. Here, then, was the outline of a Service—a new Service to deal with a new problem: the treatment of civilian casualties due to enemy action. Never before in the history of the world had it been considered necessary to cater for such a contingency

A New Problem and a New Service

All the experience of the Ministry of Health had been in peacetime associated with health problems, and its only contact with hospital affairs and those actively engaged with hospital practice had been through its agents, the County Medical Officers. In starting this new Service the Ministry very correctly harnessed it to the existing civil practice, including the voluntary hospital system, but, however much it could rely on these systems, it had to take decisions without previous experience of many of the problems. There was bound to be, there could not help being, a certain rigidity, a bureaucratic tendency to procrastination that to many people appeared unforgivable in such a crisis. The apparent dilatoriness in coming to decisions was in some cases correct, experience and time showing that the requirements suggested were in fact not necessary. The Ministry's difficulties were indeed great, and it was hampered by its very slight knowledge of the very complex problems associated with hospital management. In many respects the schemes were well thought out and well carried through, and I might instance one. Just before the outbreak of war the Ministry came to a financial arrangement with the voluntary hospitals for possible casualty services. A fortnight after war broke out the individual hospitals received their first payment.

When war did eventually come the E.M.S. came into being, the upgrading in the hospitals was at once begun, and staff, both medical and nursing, reported to their hospitals. That the confusion was not greater was really remarkable. The staffs of the London hospitals had uprooted themselves, the old values had disappeared overnight, and they found themselves in strange surroundings, trying to adjust themselves to new conditions. Their clinical work had disappeared and there appeared no immediate prospects of their having any to do. As they looked round their new quarters the scene appeared bleak, and the theatres and wards among which they found themselves rudimentary, with an almost complete absence of those efficient arrangements which had been so much part of their life that they had never stopped to inquire how it had all been done and how many years of planning and forethought, with the expenditure of large sums of money, had gone to produce the ordered effect to which they had been accustomed. After the first shock they started with the greatest good will to reproduce in these new hospitals a replica of the old. The Emergency Medical Service owes a tremendous debt to its medical officers and nursing staffs for the way in which they dealt with this situation: the energy expended was immense and the results dramatic. Criticism there was, but it was chiefly constructive, and difficulties and deficiencies were overcome frequently by the critics themselves. The next few months are known to you all. Instead of civilian casualties there was a lull, and London, instead of being emptied, carried on almost normally; this meant for the medical profession that the civilian sick returned to the out-patient departments of the hospitals and arrangements had to be made for their treatment. Readjustments had to be made, and the Ministry decided to transfer cases requiring treatment into the Sector hospitals. These hospitals were not equipped for peacetime work and the influx of civilian sick meant further improvement in the equipment of all departments. This process had to be a gradual one and still goes on, and the civilian sick continue to be treated in the Sector hospitals.

Certain hospitals throughout the country were earmarked as convoy hospitals, and to these hospitals the Army sick were brought from France, but it was not until the Germans invaded the Low Countries that any wounded were received, and not until the retreat did the E.M.S. have to deal with any large numbers of wounded. With the evacuation of the Channel ports large numbers of casualties were treated and the efficiency of the medical service was tested, and I think we can say that it stood up to that test, and the surgical work done—it was chiefly surgical work—was well done. Any criticism there might be arose from the fact that some medical officers were not aware of the great facilities of the Service, and had the feeling that if a case came into their hospital it was up to them to treat it and see the case through, rather than have it transported to another hospital further afield where there was less crowding or better facilities for special cases.

In August and September air raids on open towns started in earnest and civilian casualties had to be treated, thus fulfilling the original purpose for which the E.M.S. had been created. Despite the fact that in these raids large numbers of hospital beds were put out of action by bombs, no undue strain was ever put on the numbers remaining; more than that, the emergency hospitals were able to continue treating the civilian sick and help to deal with the large population of chronic sick that had been evacuated from damaged hospitals in the target areas.

It might be said that this was as it should be, that it had a year on war footing in which to prepare, but a year is a short time to build up such an edifice. The Army, Navy, and Air Force had had a long time to build up their medical services, and their duties were defined; but, as I have tried to show, the Emergency Medical Service had constantly to take on new duties and adapt itself to fresh calls. Almost every three months some major event determined new duties, but such was its elasticity that it was able to meet them and gradually consolidated its position.

Decentralization of the Urban Sick

There are those who have said that someone, it was never quite stated who, invented the Emergency Medical Service as the beginning of a State Medical Service. I do not think that this is true: in some ways I feel sure that the last thing that the Ministry of Health wanted was to be saddled with any such project. Nevertheless the E.M.S. had not been functioning very long before it became clear that a new conception in the medical service had come into being almost overnight. The idea of decentralizing the treatment of the urban sick was not new, it had been advocated for many years; in fact whenever one of the large London hospitals was due for rebuilding many suggestions would be made for its removal from the old site

further out into the periphery, but only in one case—that of King's College Hospital—did the hospital authorities, before the last war, carry through such a project, and more recently a provincial city has removed its hospital service outside the centre. The reasons that prevented such a movement were, among others, the difficulty of getting patients to consent to go out because their relatives would not be able to visit them and the possible difficulty in connexion with the consulting staffs. These have not proved insurmountable. The patients in the Sector hospitals are still visited by their friends, and the consulting staffs have found that travelling to and from the Sector hospitals has not been so difficult to arrange as was anticipated. It would therefore seem that the principle of keeping a small hospital in the centre of the urban district, with an adequate out-patient department, and transferring the sick to a peripheral hospital situated in a green belt outside has been proved.

We now have something to guide us in the future. In the planning of the whole emergency service mention has been made of the regional system. The Minister of Health has already, in connexion with the Nuffield Trust, seen the increased possibilities that are opened up by this war-time measure. It would be fair to say that in our large cities and towns the sick have been well looked after in the past, but there has been overlapping and reduplication of many services, with consequent waste of money and effort.

In the country districts conditions are not so satisfactory in respect of treatment of the sick. Enlightened and perhaps richer counties have taken advantage of the Hospital Act, which permitted them to set up an adequate hospital service in their areas; others have not been so forward, and adequate facilities in these have had to depend on small voluntary and cottage hospitals that had nothing like sufficient accommodation and could only deal with the fringe of the problem.

The difficulties facing regional control are undoubtedly great, for the regions include several counties and borough councils, so that a new method of control, both provincial and other, will have to be evolved, the county control disappearing, but it would be unthinkable not to make use of the enormous experience of the County Medical Officers and their staffs in any such scheme; the work they have done in the past in the evolution of the present county hospital system has been immense.

The fallacy of all policies connected with medical services is the position of the doctor in the social scheme. We have trained the lay public and ourselves to regard our position in the economic structure as that of a consultant. Some change in this outlook will have to come. Medical men from time to time will have to be given some kind of executive authority and the medical profession will have to be ready and willing to assume that authority, so that medical measures for the improved health of the nation are not left to county hospital committees.

Sketch of a Regional Scheme

Let us for a moment sketch in very broad outline a picture of what such a regional scheme might look like. A series of small hospitals with full out-patient departments in the urban districts; outside these districts in a green belt one or more large central hospitals providing accommodation and facilities for all specialties and dealing only with acute sick on the same pattern as the large voluntary hospitals that we know to-day. Further afield, depending naturally on geographical circumstances, a number of satellite hospitals receiving the more chronic type of cases, such as tuberculosis, those cases known as the chronic sick, and in each region convalescent homes for children and adults. Let us now trace one or two cases typical of the hospital patient of to-day and see how they would fit into such a scheme. A patient with gall-stones or cancer would seek advice at an out-patient department and be seen by the appropriate consultant, who would advise hospital treatment. The case would be admitted centrally and transferred to the large acute hospital to one of the consultant's beds in that hospital. After investigation and appropriate treatment the patient would be sent for convalescence, or, if inoperable, to his own home or the satellite hospital for the chronic sick. With another, a patient with tuberculosis, the same procedure would be adopted; he too would be sent for investigation and treatment to the larger hospital or direct to the satellite sanatorium. The acute case would be dealt with at the urban hospital, but the patient would be transferred to the periphery as soon as he was fit to travel.

At this point someone will say, "But this is a State Medical Service," and at once sinister thoughts creep in about the curtailment of that liberty for which we are supposed to be fighting. I would say that this was a State service, a proper State service, but it would be no more than what the Emergency Medical Service is attempting to do to-day with a free medical profession. Such a scheme has to be harnessed to finance, and it is here that the profession becomes nervous, believing that money means not so much control as interference. This need not be so. In the past the medical schools have been given large grants of money through their universities, but there has been no interference with the way individual schools have carried on their affairs. That the money granted should be spent in a proper manner is all the control that has been asked or granted, the school authorities being allowed to carry on their activities as they thought proper; no doubt the presence of these grants does mean that a broad general plan is followed, but that is not interference. In such a regional scheme as has been outlined some similar system of linking the financial problem might well obtain. It has already been suggested that the voluntary hospitals might have their resources pooled under a Hospitals Corporation, on lines like those of the British Broadcasting Corporation. The suggestion might go further by pooling all money that to-day goes to the hospital services, under a National Medical Corporation, or some such body.

Surgeons of the Future

In such a scheme as this surgery will play a large part, and the surgeons of to-day should be stirring and asking themselves how they stand; they are particularly fitted for such a task. Their minds are not warped by the destruction that is going on among the nations to-day; they are continuing their work of healing, and when peace comes they will not have to wrench their professional minds back from destructive to constructive effort in the way other walks of life will have to do. It is right, then, we should ask ourselves how we can improve the surgery of the future in any reconstruction that takes place. Many more surgeons will be required if the surgical work of the nation is to be properly done. It would seem to some that the haphazard ways of the present might be improved on, that we should ask ourselves what constitutes a surgeon. Is a surgeon a man who goes out into a country district and calls himself a surgeon, or is he a man who takes a higher qualification in surgery? Broadly speaking, neither: the first may fail from lack of knowledge, the second from lack of judgment. He should be a man who in the opinion of his teachers has enough knowledge and experience to undertake surgery, who has served an apprenticeship in surgery. The carpenter and the cabinet-maker work in the same medium, yet the one requires a different apprenticeship from the other, and we expect a more finished class of work from the latter.

We must ask ourselves, then, if these surgeons of the future should not have more experience under recognized teachers after their final surgical examination, and whether such men going out into the country under such a scheme should not be responsible for the regional surgery of the future, perhaps chosen by a committee of the College of Surgeons. In this connexion I should like to make one observation about the teaching of surgery. As one sees more and more of surgery one never ceases to be astonished at the recuperative and healing power of the human body. We are seeing this almost daily in war casualties: men and women with wounds that seem as though they must kill, or cripple the patient for life, recovering almost full function. We as surgeons have to inflict wounds on

patients. We should see to it that we do not take advantage of this astonishing phenomenon of human recovery, but that we recognize it humbly as an aid to our art, and that we teach our assistants to treat it in the same way, so that when they leave us they go out with judgment and gentleness as good surgeons.

At this moment, waiting as we do on the edge of a volcano, waiting for the church bells to ring out not war and peace but war and destruction, it may seem difficult to turn our minds to the future, but we all desire that that future should be better than the past, and we must see that whatever reconstruction takes place the individual character of British surgery is maintained for [illegible] character which is one of its greatest possessions.

CANCER RESEARCH IN WARTIME

REPORT OF EMPIRE CANCER CAMPAIGN

The seventeenth annual report of the British Empire Cancer Campaign, which was presented and adopted at the annual meeting, seems to have exceeded [illegible] wartime attenuation, and its (nearly) three hundred pages are filled with information from forty or more research departments at home and overseas. Appeals on behalf of the Campaign ceased on the outbreak of war, and cancer research, so far as it can be kept going is financed out of capital funds. Thanks to this policy, all the more important investigations have been continued and [illegible] able work is being done.

Carcinogenesis

Several of the research centres make reference to investigations on carcinogenic substances. In one experiment undertaken in the department of experimental pathology of the University of Leeds the morphology of one hundred and sixty tumours induced by carcinogenic hydrocarbons in the subcutaneous tissues of mice has been investigated. As was to be expected, sarcomata preponderated, but twenty-three examples were found of adenocarcinomata, nine of them unassociated with other types of growths. These tumours occurred only at the site of injection of the hydrocarbon, and from their histological appearance were directly to be attributed to its action. Such an occurrence has not previously been described. At the Chester Beatty Research Institute of the Royal Cancer Hospital evidence has been obtained which confirmed the theory that extracts of some human livers produce sarcoma in mice. Eleven such tumours have been obtained with four different groups of extracts.

A report from the Oxford University Research Centre of the Campaign summarizes the present position of the role of irritation in carcinogenesis by classifying skin irritants into five categories: (1) chemical (namely, the highly specific hydrocarbons); (2) physical, including such agents as x rays and ultra-violet light; (3) anti-carcinogenic irritants, such as mustard gas and croton oil; (4) co-carcinogenic irritants, such as croton oil, which, though not in themselves carcinogenic, augment the tumour-producing action of carcinogens; and (5) non-specific irritants, including the great majority of skin irritants.

At other research centres, notably Leeds, the part which heredity may play in cancer, both in man and in animals, continues to be studied. A Yorkshire inquiry, which took cognizance of over 400 family groups, has not so far—it is still incomplete—revealed any striking evidence to suggest that heredity plays an important part in breast cancer in women. On the other hand, some work from Holland is quoted, relating to 660 family groups, in which it has been found that the female relatives of women with breast cancer suffer from this disease very much more frequently than do the rest of the female population. It is pointed out that, although it has been known for some time that heredity can influence the incidence of breast cancer in mice, this should not be applied too closely to the problem in man, because the conditions of mating necessary to demonstrate the effect in mice—for example, very close inbreeding, necessitating brother–sister mating—never obtain in any civilized community.

Clinical Research

A large section of the report is taken up with an account of the work of the Clinical Research Committee, which was started by the Campaign three years ago. By the co-operation of a large number of individuals the cancer cases registered at all or nearly all the London hospitals have been taken and tabulated, with a view to bringing out age and sex distribution, incidence of carcinoma of the breast in parous and non-parous women, effect of treatment, and innumerable other points. The results should prove of great value when sufficient time has elapsed, because here is a pool of unselected cases, registered by comparable stages as recorded at the time of examination, and showing the proportion unsuitable for treatment when first seen.

It would be as well to describe fully the basis of the method in these successive annual reports, for it is assumed that the reader of this report is familiar with the method of recording and tabulation first described in the report for 1939. Moreover, in the general summary, which gives the site of the cancer in the 7,872 cases that have been coded and states that 2,915 are still living, there is no indication of the survival time. In several of the dissected tables, such as those concerning the family history of breast cancer, the relation of breast cancer to the number of children and miscarriages, and also to lactation, the high percentage of cases in which it has to be admitted that the particulars were not stated makes it impossible to draw any useful conclusions from the figures. It is hoped to eliminate these statistical errors in future by a more detailed questionary. The analyses in this report relate to breast cases and to mouth cases. With regard to the latter, which accounted for 6 % of the total number of cases registered, it is shown that carcinoma of mouth and pharynx is predominantly a male disease, and that the incidence is very low up to the age of 50.

Much other work is referred to, including experiments in radiation, dosage measurement, and neutron research. At St Bartholomew's Hospital the million-volt x-ray apparatus has been running at the full since February, 1939, and over 150 patients have been treated without mishap. Under the auspices of the Radium Beam Therapy Research the construction has begun of a pressure-insulated electrostatic generator and x-ray tube which is planned to reach an output of two million volts.

The Duke of Gloucester's Tribute

At the annual meeting of the Campaign Lord Hailsham, the Chairman of Grand Council, read a speech by the Duke of Gloucester, the President, who was prevented by military duties from attending. His Royal Highness said how glad he was to learn that neither the difficulty of ensuring the adequate provision of funds which cancer research required nor the direction of the efforts of skilled research workers into other channels had prevented admirable progress being made both in London and in provincial centres. The list of grants made to research centres by the Campaign at headquarters alone amounted to over £34,000 for 1941, or £2,000 more than last year.

C. C. Ling, S. S. Taur, P. C. Heuer, and S. Y. Yang (*Chinese med. J.*, 1940, **57**, 11) performed 110 sternal punctures and an equal number of blood cultures on typhoid and paratyphoid patients and found that, as compared with blood culture, sternal puncture yielded a distinctly higher percentage of positive results, and, owing to the heavier infection in the bone marrow than in the blood, culture gave a more rapid and abundant growth.

CIVILIAN MORALE: MEDICAL ASPECTS

A meeting of the Paddington Medical Society was held on February 11, when Dr. A. BALDIE gave an address on some medical aspects of civilian morale and crime in wartime.

Dealing first with crime, Dr. Baldie said that in spite of new wartime offences and of the opportunities for looting and disorder which black-out and raid conditions presented, there had been less crime during the past winter. Crimes of violence in particular had diminished, owing to the inhibition of social activity as a result of air raids. The evacuation of large numbers of children seemed to have lessened juvenile delinquency, although the occurrence of child neuroses was more noticeable among the children who had been evacuated than among those who remained in the cities. Another factor to be considered was the drafting of large numbers of young persons of both sexes from civilian into Service life, a factor which at present had led to a reduction in sexual and other offences, though ultimately the effect might be the other way. Kleptomania was more prevalent than the reported proceedings in police courts might lead the public to believe.

Turning to a wider field, Dr. Baldie said that doctors were faced at present with many problems of group and communal life, the solution of which depended upon the application of medical and ancillary sciences; these were problems touching on nutrition, adequacy of rest, personal and social hygiene, and occupational efficiency. Such matters as sanitation and medical inspection lost a great deal of their value so long as people in industry were wrongly placed, had insufficient hours of sleep, and had to travel long distances to work. Mass anxiety was one social danger which could be avoided if it could be foreseen, or controlled if it occurred. Among the defences against such anxiety a return to religious belief might be one of the most effective for some people. The influences of ideologies of one kind or another had been somewhat demoded by the war. No doubt education in the fullest sense of the term was called for if the people were to have an understanding and appreciation of what was at stake. The stoic endurance of Londoners during the period of intensive air bombardment was a matter for pride. Dr. Baldie gave an analysis of mass anxiety, its successive phases, its possible development into panic, and its remote effects, such as the persistence of the hiding and shelter habit. There were many who were immune from the habit of going underground, though perhaps in some cases this was due to a previous claustrophobia, but there were others who at the first alarm resorted to the shelters, persistently returning there in spite of a series of quiet nights, and suggested the attitude of the escapist whose only use for life was to avoid it.

In all these conditions where there was an aggregation of people in small spaces in various conditions of emotional tension the doctor had the opportunity of serving his patients by persuasion and suggestion as well as by more peremptory action. It was important that he and all those who had to deal with groups should understand the nature and significance of habit and behaviour in an abnormal environment, and particularly the morbid reactions of one individual upon another. Such understanding might prevent in many cases months and years of neurotic disability. It was well to remember, too, that even acute panic reactions were not major diseases and did not require removal beyond the range of immediate danger. The value of activity as an antidote to fear had been confirmed in practice. Fear and pessimism were more likely to affect those who were doing nothing.

Finally, there was the need for right leadership. Dr. Baldie gave a long list of qualities desirable in a leader: physical health and fitness, intellectual and technical ability, integrity (corresponding closely to what the psychologist meant by integration), alertness and attention, and ease and quickness of response, a sense of justice, a capacity for sympathetic imagination, resoluteness, equanimity, a sense of humour, and a concise and effective philosophy which could be expressed in a few sentences. If there was any one defect from which the vast organization of civil defence suffered it was not in the incapacity of its leaders, but in the fact that owing to the swiftness with which it had to be brought into being many of the leaders had so far not found their *métier*.

In the discussion Dr. Baldie further explained his reference to the defensive value of religious belief. He was concerned that the strong suggestive value inherent in such belief should be available for the comfort and security of those who could possess it. No doctor, of course, would insist that his patients must be religious, but to some people the comforts of religion were very real.

Dr. G. DE SWIET, from the chair, differed a little from Dr. Baldie in his conception of leader. In his view the leader must be the embodiment of average characteristics, with a good deal of greed, conceit, and verbosity. Not a little of the strength of this country, he said, was due to the fact that owing to the constitution of our people the question of leadership was not so essential as it was in some other countries, and change of leadership did not entail revolution.

MOBILE HOSPITAL FOR FREE FRENCH FORCES

One of the exciting escapes from France last summer was that of the Hadfield-Spears Ambulance Unit. It disappeared when the Germans occupied the country, but the members, though minus their equipment, turned up in England, followed their French comrades to camp, and resumed the care of the men they had been in France to serve. At General de Gaulle's training camp the unit has been running a hospital and canteen, and two other canteens for the Free French Forces in London have been under its control.

The unit has now got together a complete ambulant hospital for service in Africa. It can be unpacked and set up ready for work within three or four hours. It is loaded on a fleet of thirty-three vehicles, twelve of which are heavy lorries, eight smaller ones, six water trucks, five saloon cars, and one lorry for *x*-ray outfit with dark-room and all equipment, and another for sterilizing apparatus. One hundred patients can be looked after at one time—fifty in beds and fifty on stretchers. The personnel consists of Mrs. Spears (wife of Brigadier-General E. L. Spears, and known to a wide circle of readers as Mary Borden) and her second-in-command, eight fully qualified hospital nurses, eight V.A.D. drivers, and fifteen French orderlies. Fifteen members of the Friends Ambulance Unit, who will drive the heavy lorries, are also attached, as well as seventeen members of the American Field Service. All these men are trained in first aid, and most of them are also fully qualified mechanics. The medical staff is French, and will probably be supplemented from the French forces in the field. It includes a surgeon and a radiologist. A laboratory worker and a chemist have also been recruited.

When unloaded the hospital will consist of five tent wards, each holding twenty beds (or stretchers), with a separate tent for infectious cases, an operation tent large enough to take two operating tables, and tents for staff and for storage. Two generating plants are carried, one for the operation tent and the other for the *x*-ray unit. There is also a well-stocked pharmacy and a laboratory with microscope and sufficient equipment for ordinary work. The equipment further comprises an oil-burning field kitchen, easy and simple to manage, a disinfestor for clothing, and the usual appurtenances of a hospital—ward screens, crutches, splints, ether inhalers, complete mastoid, dental, and ophthalmological sets, an outfit for cranial surgery, as well as the usual surgical instruments, with bandages and dressings. Supplies, including car spares, are available for six months; in other words, should the hospital be cut off from communications for six months it would be able to function completely. The only commodity it does not carry is food, which will be supplied by the French Army.

The organizers have kept the hospital on French lines as much as possible. The staff will have their own uniform and badge, and when in uniform will also wear the badge of the Free French Forces.

AWARDS FOR GALLANTRY IN CIVIL DEFENCE

The award of the George Medal to Dr W S W[illegible] medical officer of health and school medical [illegible] West Bromwich, and to Miss E. G. Thomas, [illegible] West Bromwich and District General Hospital, [illegible] in a *Supplement* to the *London Gazette* dated [illegible]

Dr. WILLIAM STANLEY WALTON and Miss EVELYN [illegible] THOMAS: "Enemy bombing started large fires [illegible] near the West Bromwich and District General Hospital. Dr Walton, who was in the control room, left to [illegible] survey of the work of the casualty services. He [illegible] tinguishing incendiary bombs and then saw the [illegible] which appeared to him to be proceeding [illegible] Hospital. He went there immediately and [illegible] hospital laundry, immediately opposite to the [illegible] was in flames, together with other buildings [illegible] to the hospital, and while he was discussing with Miss [illegible] the matron, the advisability of evacuating [illegible] bomb fell which demolished the hospital laundry. [illegible] the matron were blown in different directions. He [illegible] decided that the hospital should be evacuated. Dr W[illegible] and Miss Thomas undoubtedly provided the leader[illegible] initiative which was a very great factor in the [illegible] carrying out of this difficult and dangerous task. [illegible] made many journeys to the first-aid post and to the [illegible] department to put in train the arrangements for the [illegible] of ambulances, and showed a complete disregard [illegible] personal safety. Miss Thomas herself very coolly [illegible] the nursing arrangements and the removal of the [illegible] ready for evacuation, and set a splendid example [illegible] nursing staff. During all this time the hospital was [illegible] to constant attack."

Local News

ENGLAND AND WALES

Tuberculosis in Wales

Dr. Powell, principal medical officer to the Welsh National Memorial Association, discussing in his latest report the effects of the war on the care and control of tuberculosis in Wales states that many of the patients who were sent home at the beginning of hostilities were most reluctant to return when admissions were resumed. Facilities for the surgical treatment of pulmonary tuberculosis have been drastically reduced. "It was estimated some little time ago," he continues, "that it would take nine months at the then rate of operating to cope with the cases already in residence at Sully, and in the meantime new cases suitable for surgical treatment are presenting themselves in increasing numbers." The number of contacts examined, always fewer "per 100 deaths from tuberculosis" than in the country as a whole, owing largely to conditions peculiar to Wales, have been even fewer in the past year. That this is due "partly to the pressure of other work" can readily be believed, but it is a pity that Dr Powell should provide those responsible for circumstances which render adequate contact examination impracticable with the justification that the decline is also due "partly to the difference of opinion which exists at present in tuberculosis circles as to the real value of indiscriminate contact examinations." That institutional treatment of pulmonary tuberculosis is unsatisfactory is shown by the fact that of 1,750 sputum-positive patients (45% of whom stayed over six months) not more than 3% were discharged as quiescent (patients who stayed less than one month were not included in these figures).

Lord Sankey on Hospital Co-ordination

At the annual meeting at Oxford of the Berks, Bucks, and Oxon Regional Hospitals Council, Lord Sankey, who expressed his good wishes for the regionalization of hospital services, one of the objects of the Nuffield Provincial Hospitals Trust, recalled his chairmanship of the Commission set up by the British Hospitals Association, which reported in 1937. The Commission, he said, at once saw the necessity for co-ordination not only between the voluntary hospitals themselves but between the State and municipal system of hospitals and the voluntary system. A whole chapter of its report was devoted to the relations between voluntary and council hospitals. It had recommended that regional hospital councils should consider the desirability of including representation of local authorities and that the Ministry of Health should be entitled to appoint representatives. There was always a question between the State and the voluntary system in this respect that the voluntary system had more freedom and elasticity. It was able to make more experiments and to do things which a State service was prevented from doing by those rigid rules quite rightly imposed by Government departments. For years these two great services had been running on parallel lines, and the scheme which the Nuffield Trust was now engaged in furthering was to unite them, a process which called for mutual tolerance, understanding, and forbearance. He hoped that in the region whose council he was addressing they would be able to "stable their horses together" and all would work successfully for the end they desired to see accomplished. He concluded with a tribute to Lord Nuffield, who, not content with serving his own age, "has extended the dominion of his bounty to heal the sick and relieve the sufferings of generations yet to come."

INDIA

Tuberculosis Work in India

The second All-India Tuberculosis Conference was held in New Delhi at the end of 1939, and the *Transactions*, a volume of more than 200 pages, has now been received. The conference took place under the auspices of the Tuberculosis Association of India, whose medical commissioner, Dr. C. Frimodt-Moeller, was chairman of the various sessions. Several of the sessions were attended by the Vicereine, the Marchioness of Linlithgow, who gave a description of the Papworth Settlement, with which her father, the late Sir Frederick Milner, was prominently associated. She begged those concerned in India to keep the colony idea in view, and to start colonies in a small way wherever possible. Several speakers in the discussions said that village settlements on the Papworth model would be the ideal after-care system for India, and the Tuberculosis Association was urged to see if they could not be established in a few selected centres. Dr. Frimodt-Moeller said that by force of circumstances the chief measure in the Indian campaign was a well-thought-out scheme of control of tuberculosis by organized home treatment. He agreed that this scheme was not the ideal one, for in the West it was known that the death rate from tuberculosis had declined most markedly in those countries in which there existed the greatest facilities for institutional treatment: but it was out of all question to create in India institutional treatment to the extent that this had been done in Western countries. A system of home treatment must be organized whereby thousands of patients would be able to get in their homes some benefit from the modern specialized treatment of the disease, and some preventive measures would be introduced against further spread. The papers and discussions printed in these *Transactions* cover a wide range, including causative factors, physical examinations, diagnosis, collapse therapy (the subject of several papers and some interesting discussions), the virtue of institutional and home treatment, and the direction of propaganda and education. It was mentioned in one paper, by Dr. A. C. Ukil of the All-India Institute of Hygiene and Public Health, Calcutta, that one million lives were lost in India annually owing to tuberculosis. He said that in view of this toll and of the shortage of beds for tuberculous patients the enforcement of the provisions of the Indian Health Acts for notification, disinfection, and segregation could hardly be expected at present, but a great deal might be done towards home segregation by tactful and sympathetic medical officers and health visitors. Evidently India is now very tuberculosis-conscious, but the fear was expressed that unless State aid is forthcoming the campaign in India would die a natural death when the wave of enthusiasm subsided.

Correspondence

Sulphathiazole Snuff for Diphtheria Carriers

SIR,—In the article by Drs. M. E. Delafield and Edith Straker and Prof. W. W. C. Topley on antiseptic snuff (February 1, p. 145) it was suggested that in view of its action on diphtheroids, sulphathiazole snuff might prove effective in the treatment of nasal carriers of the diphtheria bacillus.

A child developed diphtheria after being in hospital for two weeks. A search was made for a carrier. It was discovered that the nasal swabs from two nurses contained the diphtheria bacillus. In the case of Nurse A. a profuse growth was obtained. In the case of Nurse B. only a few bacilli were found and the swab was negative when repeated. Both nurses were given a sulphathiazole snuff. Following the suggestions in the article referred to above, the proportion of sulphathiazole was increased to 30 parts with 70 parts of magnesium carbonate, and the snuff given more frequently. Progress was as follows:

Nurse A.—Schick test negative. First day, snuff taken two-hourly. Some stinging in the nose and watering of the eyes in the evening. Second day, nasal swabs negative (taken 10 a.m.). Snuff taken six times (approximately three-hourly). No discomfort. Third day, nasal swabs taken before any snuff had been taken proved negative. Snuff taken four times. No discomfort. Fourth day, nasal swabs negative. Snuff taken four times. Fifth day, no further snuff taken. Seventh day, nasal swabs negative. Twelfth day, nasal swabs negative. Presumed free from infection.

Nurse B.—Snuff taken as above for three days. All nasal swabs negative. Seventh day, nasal swabs negative. Presumed free from infection.

Nurse B. can hardly be considered to have been a carrier. The rapid way in which Nurse A. was freed from infection suggests that the method is worthy of a thorough trial.

We are indebted to Miss Lucy Wills for her help and suggestions.—We are, etc.,

A. M. M. PAYNE,
Senior Resident Medical Officer.
GLADYS M. AUCHINLECK,
Resident Pathologist.

Royal Free Hospital,
London, W.C.1, Feb. 18.

Chemoprophylaxis of Anaerobic Infections

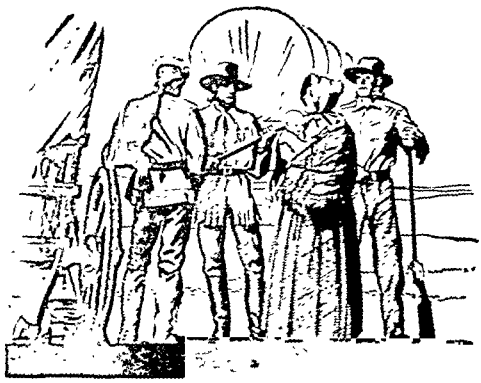
SIR,—In Dr. Frank Hawking's valuable study of chemoprophylaxis in anaerobic infections (February 22, p. 263) there is one subsidiary point which deserves more attention than he himself gives it. Having described in detail the prophylactic action of sulphathiazole and other sulphonamide compounds, he briefly mentions similar experiments with proflavine. Apparently the application of 1% or even 0.1% proflavine will "certainly prevent" infection under the conditions of these experiments, a fact noteworthy enough in itself. But further than this, whereas after successful application of sulphathiazole films from the wound made on the third day "invariably demonstrated great numbers of Clostridia," wounds treated with proflavine and opened on the third day showed "only small numbers of bacilli."

I do not wish to place undue emphasis on his very brief description of what may have been an experiment in only a few animals, but as this record stands it suggests that proflavine is not merely the equal of sulphathiazole for preventing infection by Clostridia but actually superior to it. Yet he apparently discounts these results and regards them as unworthy of further attention, only for the reason that acridine compounds gave "mediocre results in the last war." This is a form of reasoning which I cannot follow: the results of controlled experimental study by a new method cannot be confounded by reference to uncontrolled clinical study made under very unfavourable conditions a quarter of a century ago. There would be some force in this argument were there any resemblance between the methods used, but there is not. Acridine compounds were used in the last war mainly for treating well-established wound infections, not for preventing them at a stage when prevention had any hope of success. I have argued recently (*Lancet*, 1940, **1**, 845) that the battlefield is no place on which to judge what antiseptics can do in preventing wound infections: casualties may not be brought in for some hours, and penetrating wounds are inaccessible by antiseptics applied in the ordinary way. I have suggested two hours after wounding as an arbitrary period delimiting prophylaxis—that is, the killing of bacteria in the cavity of the wound—from the treatment of infection thereafter entering the surrounding tissues. Dr. Hawking has adopted this period himself, and found that sulphathiazole introduced two hours after infection saved only one-fifth of his animals (two-thirds having survived when it was applied immediately); introduced after six hours it saved none. This treatment after six hours is surely more nearly the equivalent of what was done with acridine compounds in the last war.

Antiseptics have had few fair trials as agents for preventing wound infections. I have consistently maintained that acridine compounds are calculated by everything we know about them to be capable of this if properly applied at an early enough stage. Dr. Hawking's experiments appear to confirm this in the particular case which he has studied. That a 0.1% solution of proflavine can do as much as or more than solid sulphathiazole is more remarkable than he seems inclined to admit, although there is perhaps a reason for this result which detracts somewhat from its general significance. The dye antiseptics have a strong affinity for fabrics, and this may have led to the concentration and persistence of proflavine in the cloth which was the vehicle of infection in these experiments with an actually bactericidal effect. I think it very probable that sulphathiazole will prove superior to proflavine if only because its degree of solubility secures persistence in adequate concentration in the wound for four days, as Dr. Hawking has shown. This letter is written only as a plea for justice to an older method, and for impartiality in interpreting experimental findings.—I am, etc.,

Harpenden, Feb. 23. LAWRENCE P. GARROD.

Trichiniasis in Britain



SIR,—The accounts by Dr. J. E. Stanley Lee (February 15, p. 237) and by Prof. L. P. Garrod and Dr. Donald Maclean (p. 240) of outbreaks of trichiniasis are of considerable interest.

A similar outbreak occurred in Pembrokeshire in November, 1939. Eight cases were investigated and all had oedema of the eyelids associated with supra-orbital pain, especially on movements of the eyes. Each had a high eosinophil count, ranging from 23 to 55%, together with pyrexia and muscle pains. One case developed a profuse but transient haematuria, which was assumed to be due to larval embolism of a kidney. In none of the cases was there any history of gastro-intestinal trouble. A peculiar feature of the muscular pain was described by some of the patients, who experienced pain after movement of the affected muscle but not synchronously with the movement.

The diagnosis of trichiniasis in these cases was suggested by their resemblance to a similar series of eleven cases, an account of which was published by Rice, Williams, and Sladden (*Lancet*, 1922, **2**, 799). This series, which also occurred in Pembrokeshire, was characterized in every case by oedema of the eyelids and a high eosinophil count, and Dr. A. F. Sladden demonstrated a few adult female forms of *Trichinella spiralis* after patient search of films of faeces pressed between photographic plates. This procedure was carried out on stools from my cases, but without success. A piece of muscle was excised and examined by Dr. A. W. Downie of the E.M.S. laboratory, Cardiff, but although a tender area of the deltoid was chosen for the purpose no larvae were found.

In your leading article (p. 245) you mention the significance of the fact that outbreaks should occur simultaneously at Wolverhampton and in Hertfordshire. It is perhaps equally significant that there should have been two outbreaks in Pembrokeshire fairly recently and that similar cases have been suspected in the same district in the intervening period.—I am, etc.,

Haverfordwest, Pembs, Feb. 20. J. F. E. GILLAM, M.B., F.R.C.S.

OF BRITISH SULPHONAMIDE THERAPY

In 1936 May & Baker introduced the the first colourless anti-streptococcal sulphonamide for oral administration made available in Great Britain — * PROSEPTASINE.* PROSEPTASINE is of considerably lower toxicity than *sulphanilamide and comparatively* tasteless.

In the same year * SOLUSEPTASINE * was introduced. A colourless sulphonamide in aqueous solution for parenteral administration.

In 1938 May & Baker gave the world * DAGENAN—M & B 693* which by its activity against the pneumococcus. meningococcus and gonococcus has proved to be one of the outstanding medical discoveries.

And now in 1940 May & Baker have produced * THIAZAMIDE,* an alternative in chemotherapy to * DAGENAN—M & B 693* for cases which prove intolerant of the latter drug. In some cases of staphylococcal injections * THIAZAMIDE * may prove superior to * DAGENAN—M & B 693.*

The range of May & Baker sulphonamides includes * SOLUSEPTASINE* ointment and sulphanilamide " May & Baker."

for smokers with sensitive throats... the du Maurier filter tip

By virtue of its filter tip du Maurier has removed the causes of irritation without in any way detracting from the fragrance and flavour of the tobacco. Three layers of pure white vegetable tissue, interleaved with two layers of cellulose fibre, protect nose and throat from Pyridine bases and non-volatile bodies, normally liable to be carried into the mouth by unfiltered smoke and shreds of tobacco. Even sensitive membranes are unaffected by the cool, clean-smoking du Maurier.

Dyspepsia in the Army

SIR,—If it were true, as alleged by Mr. Reginald T. Payne and Dr. C. Newman in their interim report on dyspepsia in the Army (December 14, p. 819), that 89 % of all dyspeptics in the Army suffer from "gross organic disease," chiefly peptic ulceration, then a rather alarming state of affairs exists. And if it were also true that "there was little evidence of minor dyspepsia" and that "exaggeration of symptoms for evasive purposes" was rare, then it would seem that the modern soldier's stomach and philosophy had undergone a radical change.

In one military hospital in the Home Command, over a period of twelve months, over 200 cases of chronic dyspepsia have been thoroughly investigated in a ward set aside for that purpose. In only sixty-four was there evidence of peptic ulceration: duodenal fifty-four and gastric ten. Chronic gastritis, achlorhydric and hypochlorhydric, gall-bladder and appendicular dyspepsias comprised only a handful. In the remainder no evidence of organic disease could be found. The latter had often been studied elsewhere and formed a floating population that drifted from one hospital to another. Relapse monotonously followed each course of treatment, while the patient's knowledge of dyspepsia, barium meals, and the ways of ward sisters and medical officers grew accordingly.

I quote only from my own experience, but it cannot differ greatly from that of other medical specialists. The statistical survey presented to the Army by Mr. Payne and Dr. Newman may not be truly representative, since their material was largely selected for them. A truer picture would be forthcoming if the collected experience of medical specialists in the different Commands was studied.—I am, etc.,

Major, R.A.M.C., Medical Specialist

Co-ordination of Mental Health Services

SIR,—The National Council for Mental Hygiene was interested in your leading article on "Hospital Administration in the L.C.C." (January 11, p. 56) and in the letter arising out of it from Dr. Francis Pilkington (February 8, p. 213).

This Council has always advocated the policy of co-ordination of the mental health services, especially co-ordination between the municipal general hospital, the mental hospital, the mental deficiency colony, the voluntary general hospitals, and the voluntary mental health organizations in each area. Much of the overlapping and many of the gaps which now exist in these services are primarily due to the fact that these bodies are working in watertight compartments. The report of the Feversham Committee which was published in July, 1939, recommended among other matters the establishment of mental health committees which would include all mental health interests in each administrative area, with co-operation between adjacent areas.

The war has already brought various mental health problems into prominence, and the problems connected with evacuation have shown the difficulties which have arisen owing to lack of co-ordination between different areas. It is to be hoped that the Medical Planning Commission of the British Medical Association will be augmented by representatives of mental health interests, and that special attention will be paid to this important question of co-ordination of the mental health services.—I am, etc.,

London, Feb. 18

Treatment of Cancer of Cervix

SIR,—The interesting analysis of cases of carcinoma of the cervix treated at the Middlesex Hospital and published by Mr. W. R. Winterton and Dr. B. W. Windeyer (February 8, p. 195) illustrates the danger of accepting conclusions drawn from statistical evidence unless this evidence is carefully analysed. From the data collected the authors conclude that "in technically operable cases a higher percentage of five-year survivals has been produced by radiotherapy than by surgery." This conclusion is open to severe criticism, for the deaths from causes other than recurrence from cancer have been included so as to weigh the balance in favour of radiation therapy. From the figures submitted we find that 64 patients of Groups 1, 2, and 3 (League of Nations classification) were treated by radical surgery. Of these 11 died as a result of operation and 24 died of cancer within five years, giving a total mortality of 35, or 55 %; 2 were untraced, and assuming these both died of cancer the mortality becomes 58%.

As opposed to this, 68 patients of Groups 1, 2, and 3 were treated by radiation, and of these 3 died during treatment and 39 died of cancer within five years, giving a mortality of 42, or 62 %. It follows, therefore, that in the series studied by Winterton and Windeyer the patient had a greater chance of living from the disease if treated by radiation than if treated by surgery. In discussing whether surgery or radiation is the better method of treatment there is little room for satisfaction for the advocates of either, for if the facts are faced the results given by both methods are at present unsatisfactory. The challenge is surely to find a better way of treating the disease, be it by surgery, radiation, or by a combination of both.

In conclusion, to avoid any misunderstanding I must say that at present I am treating my cases of cervical carcinoma by radium and deep *x*-ray therapy, but like so many other workers I am not satisfied with the prognosis, nor can I be satisfied with the conclusions drawn in favour of radiation therapy from the analysis of the Middlesex records.—I am, etc.,

JOHN STALLWORTHY.

Oxford, Feb. 18.

Medicine in a Changing World

SIR,—I have read with interest both the summary of Sir John Orr's excellent address (January 18, p. 73) and also the ensuing correspondence. Your editorial phrase (p. 91), "the cobbler must stick to his last," has already come in for criticism. It seems to me that there is both a sense in which it is right and a very important sense in which it is wrong. That medicine can contribute most to politics by standing aside and giving testimony as the expert witness I am convinced. On the other hand, it seems to me dangerous to assume that our contribution has the definition of the cobbler's. There are many ways in which the traditional approach of the doctor to his patient is changing. The fact that we may try to tell our patients what food to get is itself a change. A further change appears when doctors figure as the paid servants of the factory. In cases of doubt the doctor has then to settle with his conscience whether he will advise for the benefit of his patient or for the economy of working hours. In a situation such as this the custom of the profession undergoes a shift because of the circumstances which surround it. What the doctor happily has stuck to has been, not his last, but his Hippocratic tradition. On the whole, he does justice by his patient no matter who employs him. There is, however, a sense in which to attempt in the modern world to cling to the Hippocratic condition is to put one's head in the clouds, for the personal value and relationships out of the understanding of which that tradition was born have broken down. One of the virtues of the modern work on nutrition is that it gives an impersonal measurement of personal requirements.

It is possible that the present hostilities represent the attempt of the English tradition to salvage personal values and relationships. In so far as we are as successful in the ensuing peace as we appear likely to be in the present war, we shall need to build a world in which there will be increasing scope for simple human things. Nutrition, as Sir John Orr stresses, concerns only a phase of individual living. It is, however, an important phase, backed by scientific sanctions. To get our society to act on what it knows about nutrition would be a great step forward.

Medical officers of health have great powers in matters of nutrition. These officers are, I believe, responsible for the education of the local inhabitants in matters of diet. I once tried to get a medical officer to introduce the Oslo breakfast into the local schools, a scheme which had some local support. I was informed that "the value of protective foods is sufficiently recognized." Such an attitude may be "sticking to the last," but it is not promoting the best interests of the patients. But then, of course, they are not—to the medical officer of health—patients, only workers.

The questions of the personal relationships, of personal health and development, and of a social order which will recognize and facilitate these, are, I think, very much the

concern of the general practitioner. He understands that to go on practising family medicine two things are necessary. His own contacts with his patients must be kept unified. And his patients must live in a world where health and development are possible. I feel with many others that, in reconstructing medicine, if more general practitioners served on the Medical Planning Commission, particularly more rural practitioners, these two essentials would more certainly be safeguarded.—I am, etc.,

Coventry, Feb. 18. KENNETH E. BARLOW.

Medical Planning Commission

SIR,—Your correspondence columns are full of criticism of the personnel of the Medical Planning Commission on two main questions: representation of general practice and the preponderance of older men. From memory the following are members of that Commission: Drs. Dain and Gregg, who between them cover insurance practice for over twenty-five years and know more about it than any other doctors in the British Isles; Drs. Bone, Pooler, and Wand have all been working on general practice problems for the same time. No one who knows these men can have any doubt as to the forcefulness of their advocacy.

With regard to the second problem, your critics may well be reminded of R. L. Stevenson's dictum: "Where youth agrees with age, not where they differ, wisdom lies."—I am, etc.,

Braunton, N. Devon, Feb. 18. HERBERT C. JONAS.

SIR,—The criticism of the Medical Planning Commission which has already been published shows that its origin, constitution, reference, and the expected results of its deliberations have caused widespread misgiving. The chief reasons for this appear to be that the Commission was conceived and appointed in secrecy by a private body which is by no means representative of the whole profession. Its personnel gives the younger members of the profession no confidence that it will be able or willing to cut away from old traditional ideas and meet the changed world, which will follow the war, with a scheme of health service in keeping with the new conditions.

Any programme for the future must be worked by the men and women who are now young, and yet only three members have been qualified since 1925. "Matured wisdom" in any assembly is essential, but in the one in question it has a strong preponderance, and unfortunately seniority sometimes stands for rooted prejudice instead of matured wisdom. It is inevitable that the older generation should think of the future in terms of the past which has served it pretty well. The younger generation on the whole have little sympathy with the past, for to them it is the parentage of the present. But not only have younger people not been invited to join the Commission in sufficient strength; there is a gross under-representation of medical women. Only two women out of a total of seventy members have been chosen, and yet they form a proportion in the profession of about one to nine men, and they will play a still greater part in the health services of the country after the war.

Preventive medicine is represented by two medical officers of health and a professor of public health, some of the most important units of the whole personnel. The bulk of the members are concerned with the curative medicine, of end-results. Few such men can have spent thirty years or more of their lives in curative medicine and surgery and escape the conviction that the better health of the people depends upon better doctoring along the orthodox lines. It is not easy for them to see that the end-results, which engross nearly all our attention, would be considerably reduced in volume if the people were fed nutritiously, housed decently, and trained in the pursuits of leisure. And yet the Commission contains no social workers, members from the Ministries of Health, Food, and Agriculture (*pace* the "observers"!), trade unions, actuaries, economists, hospital managers, or laymen of the local authorities. We should have thought also that, as any future medical service should be primarily a health service, a member from the Pioneer Health Centre of Peckham should also have been elected. The vitally important branch of medicine—the care and treatment of the teeth—should surely have strong representation on a Commission for reconstruction. But perhaps the chief omission is the patient. A national Commission appointed to deliberate on a Service should be composed chiefly of the party for whom the Service is designed, advised by technical experts—in this case the doctors.

The terms of reference are vague and difficult to define. They are: "To study wartime developments and their effects on the country's medical services, both present and future." Presumably "wartime developments" refers to political, social, and economic changes which may emerge from the impact of the war on the people, but we cannot know yet what these will be. And it is not so much what may be their "effects on the country's medical services" which will matter, but how these services may be so reorganized as to meet the changed circumstances and demands of the people. The reference is vague enough to justify your leading article of January 4 (p. 19), anticipating the prediction of "the cynic" that seventy Commissioners may produce a low-grade compromise as the lowest common denominator of their views and prejudices.

The need for radical reconstruction of medicine, to give it a new orientation towards health as well as disease, is obvious to most of us, but surely, as Sir Ernest Graham-Little suggested, it should be the work of an independent Commission, to which the B.M.A. should, in common with other bodies, have been invited to send its representatives instead of assuming the role of convening authority.

But these and other criticisms imply that by modification on these lines the Commission could be moulded into a useful instrument. It may perform a service as a fact-finding body, but inasmuch as its emphasis is on "effects on the country's medical services" rather than expansion and reorganization of health services, I feel that the B.M.A. has approached the problem from the wrong angle. The health services form a vast network of influences on the individual and family of which medicine is only one part. The Medical Planning Commission may make certain recommendations touching the profession, but, in view of the probable demands of the public after the war, it is improbable that such sectional recommendations can be integrated into a new system of health service.—I am, etc.,

London, W.1, Feb. 12. ALECK BOURNE.

SIR,—If the Medical Planning Commission as at present constituted makes a report, and if a Royal Commission considers this report and makes another, and if Parliament then legislates according to its findings—all very hypothetical suppositions—by that time four-fifths of the original commission will be statistically dead, and, although it may serve them right, this form of protracted maternal death in childbirth is, I suggest, very unsatisfactory for the child.

A fair way of getting a representative commission is for each age group to send members according to its numerical strength; thus, if there are 4,000 30-year-olds on the *Register* they would send four members. The only exception that seems logical is to have the medical students also represented. It will, of course, be urged that as age increases so does experience and that this should be utilized, but the worst of experience is that it is so often counterbalanced by a static state of mind, lack of vision and altruism, and too often forgetfulness of first principles. In the last year or two quite a number of experienced soldiers and politicians, whom it would be tactless to name, are cases in point.

Man, it would appear, reaches his mental prime about 30, after which a more or less slow degeneration sets in, yet not a single member of the Commission is of or below this age. Personally I hope that just as the young men and women who are going to win the war for us should have the major say in the peace, so should the younger members of our profession have the planning of it, for they and they alone will live to see these plans in extended operation.—I am, etc.,

Beckley, Sussex, Feb. 13. C. G. LEAROYD.

SIR,—Critics of the Medical Planning Commission contend that more comprehensive representation on that body would ensure a satisfactory outcome for its deliberations. Permit me to say that the larger this already large Commission becomes the more it will be an arena for those various conflicting points of view whose only common sentiment is that things cannot go on as they are. Yet before the end of next winter war conditions are likely to demand swift, efficient co-ordination of the existing medical services rather than dignified deliberations over doubtful possibilities. Many fat chickens are being counted before they are hatched, and my

suggestion is that some planned action be now initiated by the Commission for the protection of the people In particular I suggest the commencement of planned research to counter the generally admitted danger of serious epidemics

Epidemic influenza, encephalitis, virulent measles, etc are virus diseases which have not yet been mastered even in the laboratory. Twenty-two years ago they killed more people than all the fatal casualties of the last war, and to-day, in company with virus diseases of animals and plants, they constitute the gravest possible threat to the lives of millions of men, women, and children. Against this threat stands a public health service and a body of general practitioners in need chiefly of new knowledge and new methods of treatment capable of stamping out virus infection in whatever form it occurs. At present the general practitioner knows very little about research and tries a large number of remedies in the most haphazard fashion. As for the research laboratories, these might have a century of peaceful security before them, judging by their published results. The biological, biochemical, physiological, and pathological journals regularly show long lists of research results on trivialities, curiosities, and rarities having little or no bearing on the urgent problems of the day. Out of experiment for experiment's sake there has grown a monstrous accumulation of uncoordinated and largely unused literature recently described by Sir Robert Hutchison as a "pullulating and fungus-like growth" (*Lancet*, 1939, 2, 59)

Is it not time that planned research was carried out by the various biological and medical laboratories under the guidance of men who know the outstanding scientific and medical problems, the most promising lines of research, and the investigators most likely to achieve successful results? If the Medical Planning Commission wishes to act as well as deliberate—and circumstances cry aloud for action—let it obtain the Ministry of Health's authority to join practitioners and laboratory workers together in planned, applied, and co-ordinated research, guided by a small group of well-informed and far-seeing men and women, in the interests of the people.—I am, etc.,

Oxford, Feb. 16. R. L. WORRALL.

SIR,—Lack of interest has kept me in ignorance hitherto of the composition of the Medical Planning Commission. Cursory glances at the correspondence columns of the *Journal* each week have, however, made it apparent that those who have elected to serve thereon may now have some diffidence in so doing.

The flower of the profession is away with the fighting Services, and as it is they who will be most affected by post-war reorganization of the profession it would be sheer presumption for those remaining at home to undertake any such planning, especially as it is certain that among them the pushing, the cranks, and the old gentlemen would be most active—the others would not have the time.

Formation of plans postulates knowledge of the material which will be available for building purposes. No such knowledge exists. We are not concerned with castles in Spain. That changes in the life of the community will be tremendous is assumed too readily; changes are only as certain as they are necessary, and post-war conditions will depend both on the duration of the war and on the possible turns in it which are as yet unknown to us. Let this farce of "planning" be stopped until the war is over, or there will certainly be the devil to pay if those returning from the war find themselves saddled with some half-baked scheme. There is more than enough real work to be done at home now—let those at home get down to it and stick to it.—I am, etc.,

Newcastle-upon-Tyne, Feb. 22. GEORGE A. MASON.

Trends in Nutrition

SIR,—I was greatly interested in the summary of Sir John Orr's B.M.A. Lecture (January 18, p. 73) and made a few notes of its content. I feel stirred to write a note in view of my experience on November 23. On that day, among other patients, there were these three who in reply to the question "Do you eat cabbage for dinner?" replied as follows: No. 1. Male aged 28 years: "I never eat cabbage: I eat plenty of white bread and potatoes." No. 2. Female aged 26 years: "I don't like cabbage, I never eat cabbage; I eat puddings or just potatoes." No. 3. Male aged 19 years: "I never eat cabbage." These three test cases are typical of scores that have come under my observation during the past ten years. Of 100 children suffering from non-pulmonary tuberculosis, sixty had an aversion to green vegetables; of thirty suffering from pulmonary tuberculosis, twenty-three had an aversion to green vegetables; of 100 young women between the ages of 15 and 20 years, fifty-three had an aversion to green vegetables. *Diet deficiency in these cases was not due either to* poverty or to shortage of supply but to dislike.

Now it appears that Sir John Orr believes dietary habits of the people can be changed by increasing the production of protective foods and by fixing an appropriate price within the means of the poor. An abundant supply of green vegetables at a price of 1d. or 2d. per lb. will maintain the consumption of green vegetables at a higher level than it would be if the price were 5d. or 6d. per lb. If the lower price can be maintained at this time of the year, then the people will certainly benefit. In this district housewives cook green vegetables three or four days a week, but when the price rises to 4d. or 6d. per lb. then only once a week on Sundays. But neither increased production nor cheapness will *alter the diet habits* of those who dislike green vegetables. This aversion to green vegetables is formed at an early age through parental ignorance—ignorance, not of food values, but of child management, of the art of persuading a child to eat something different.

An agricultural policy that aims at increased production, an economic policy that maintains a moderate price, an educational campaign on the nature of foods, are all essential, but will not be sufficient to overcome diet deficiencies. There will be necessary a widespread campaign educating parents and guardians in all classes of the community in the art of managing the faddy child.

If space permits, I should like to comment on the suggestion that the frustrations of life tend to be associated with poverty. Concerning tuberculosis, I agree that diet deficiency plays an important part—but that the actual manifestation of the disease is associated with some frustration; but I do not agree that all such frustrations tend to be associated with poverty, nor with the logical outcome of the argument that the frustrations of life would be removed by removal of poverty. In my experience the frustrations of life associated with the manifestation of tuberculosis fall into three or four categories: (1) bereavement; (2) disappointment in love affairs, broken families; (3) failures in examinations or business, or loss of work; and (4) other emotional shocks. Poverty may enhance these states but it is not a determining factor. Individuals who break down under the stress of life do so not because of poverty but because they have acquired a temperament difficult to adjust to failure and defeat. They are the maladjusted, the misfits of society; they are to be found in all classes of the community, in homes of wealth and of poverty. This type of temperament will not be eliminated by the elimination of poverty but only by wise home training.—I am, etc.,

P. A. GALPIN,
London, E.13, Feb. 4. Tuberculosis Officer.

Village Settlements for the Tuberculous

SIR,—With the death of Sir Pendrill Varrier-Jones has departed a pioneer in an aspect of the care of tuberculous individuals which was almost entirely neglected in the past, until he directed his efforts to this field, and which is still grossly neglected in the present. It occurs to me that he—like all true pioneers—would have derived his greatest satisfaction from that recognition of the importance and value of his work which a wider adoption of his methods would have afforded.

That a nation-wide need exists for workshops and factories where workers with arrested tuberculous lesions can be employed under special conditions and under medical care, no one working in anti-tuberculosis schemes can deny. Why, then, have such arrangements not become part and parcel of all anti-tuberculosis services, as, I contend, they should have this long time past? There can be little doubt that the answer to this question is to be found partly in the competitive nature of our society and partly in the tedious reluctance of public authorities and Government bodies to allocate finance for adopting new measures for the protection of the public health, even

when the efficacy of such measures has been clearly proven. How else is it to be explained that such institutions as Papworth Village Settlement, Preston Hall, and Peamount Village Settlement have not been copied all over the country? In a similar light stand such institutions as the Cripples Training College at Leatherhead, Surrey.

Much of the interest which these institutions have evoked appears to be derived from the fact that they are still regarded as "bold and courageous experiments," and that they are the exception rather than the rule, as well as from the excellent work which they have undoubtedly accomplished. Almost all of them are dependent or semi-dependent on charitable sources for their income, and in 1937 the Cripples Training College already referred to had to report that ". . . the financial position leaves much to be desired. Running costs exceeded receipts by £357, while of the original loan of £6,000, £2,000 has still to be repaid. . . . Contributions are therefore most urgently required, and until a more stable foundation can be established the work of the college must be seriously hampered." Further, though a high percentage of trainees from this college are placed in industry, work cannot be guaranteed in a society suffering from a chronic unemployment, which affects healthy, let alone crippled, workers. And again, the marketing of commodities produced by patients and workers in such special institutions raises innumerable difficulties. I know of at least one mental hospital where the excellent articles created through the craft activities of the patients are stored in a large room, only seeing the light of day for exhibition purposes, their sale being prohibited because of the objections of local tradesmen.

All this is in marked contrast to what could be achieved in this field of medical economics in a society released from the restrictive influence of the profit motive.

In the U.S.S.R. the principles and practices so strongly advocated by Sir Pendrill Varrier-Jones in the care of tuberculous workers are universally carried out through the network of "labour prophylactoria" attached to the institutes of tuberculosis. I was able in 1939 to visit the Leningrad Institute of Tuberculosis, and there saw for myself the excellent work being carried out in the training and re-education of tuberculous workers. Many of these workers eventually take their place in production in special factories and workshops, working entirely outside the various schemes of planned production and under constant medical supervision. In the U.S.S.R. such provision for tuberculous workers is universally applied, since it is regarded as an integral part of treatment. A further important point is that for such workers—whether disabled through disease or injury—work could, in a socialist economy, be guaranteed, and this is in fact what occurs in the U.S.S.R.

This brings me to my final point, which I will put in the form of a question. Are we to wait until our capitalist form of economy is replaced by one based on socialized production before the Ministry of Health (acting in conjunction with the various local authorities and, in the case of Wales, with the Welsh National Memorial Association) can be expected to adopt such measures on a nation-wide scale; or is the Government prepared *now*—as an earnest of its avowed intention to "build a new world after the war"—deliberately to foster and encourage the initiation of schemes of this kind for the training and employment of tuberculous persons? The answer to this question is, I maintain, one of tremendous importance, as it involves a question of policy.

To adopt the latter course would solve one of the most difficult and pressing problems which face tuberculous patients when they leave sanatoria, and would go far to break that vicious cycle of "tuberculosis—poverty—tuberculosis" which is so often established when the person affected is a family wage-earner. It would at the same time be the highest tribute to the memory and work of Sir Pendrill Varrier-Jones.—I am, etc.,

Neath, Glamorgan, Feb. 17. T. FRANCIS JARMAN.

The Evacuation Problem

SIR,—May I through your columns draw the attention of all medical officers of health and all medical men in the public services to the importance of protecting the world and the coming generation by securing the evacuation of children in a sensible way. At present the L.C.C. is spending public moneys extremely wastefully. This can be tested by any health visitor inquiring from the women of the poorer districts of London the truth about evacuation. They will find that a considerable percentage of children have never been evacuated at all, because mothers say that they cannot let their children go away from them. Another high percentage have been evacuated once, and they have come back again. A fair number have been evacuated twice, and a percentage have been evacuated three times over. They will also find a fair number of mothers who are intending to have their children evacuated again as soon as the weather gets better. The idea growing up in their minds is that they can use the evacuation scheme as a means of getting a holiday in the country for themselves and for their children. The L.C.C. pays fares down there and allows a billeting allowance while they are away, and this means that they can get a cheap holiday at a charge which is of no benefit to the country, for the welfare of England needs the *permanent* removal of children from the great towns.

This matter is becoming serious and urgent. Those who are working among the slum children of London are finding that the disease of rickets is beginning to increase; that pale faces, tense nerves, weakened bodies are becoming more and more prevalent among the children who are spending most of their time in shelters and underground habitations. The children are suffering from lack of light, lack of air, lack of fresh vegetables, and lack of the ability to spend a halfpenny or a penny upon oranges and bananas and apples whenever they feel hungry. In addition, there is a shelter rash beginning to show itself which is not scabies, but which is probably the result of these unhealthy conditions under which children are living. Not only are the children deteriorating physically, but, having nothing to do and no school training, they are becoming mentally listless and degenerating in all respects.

The matter is extremely serious, and it is only the medical profession, by wise and powerful influence, which can make our politicians face what is essential for the welfare of the coming generation. It is in the country alone that the children can now be provided with a sufficiency of those greens and salads and fresh vegetables which, essential as they are to the children's health, are now lacking in their dietary.—I am, etc.,

London, W.1, Feb. 23. JOSIAH OLDFIELD.

Bell's Palsy and Herpes Zoster

SIR,—A few weeks ago I was called to see a man aged about 65 who was suffering from a very painful erythema of the left side of his face, while here and there were a few very tender red lumps closely resembling boils. The nature of the erythema was not very clear to me until the following day, when typical herpetic vesicles were visible on the cheek, in the hair over the left occipital region, and down the back of the neck for a distance of about three inches below the lower margin of the hair. He had had an extremely painful night. As the nature of the lesion was now obvious pituitrin was given, and the following morning I was told that the relief had been wonderful. Four daily injections were given, and the vesicles and pain diminished with equal rapidity.

About a fortnight later I received an urgent summons from his wife, as "something terrible has happened to my husband." Expecting at least a corpse by the time I arrived, there was nothing worse to be seen than a typical Bell's palsy on the same side as the herpes. After about three weeks there was a marked improvement as regards the Bell's palsy.

It seemed natural to assume that the herpetic virus was the cause of both conditions, though I do not recollect ever having seen or read of this occurrence. Your contributor Major J. D. Spillane (February 15, p. 236), however, appears to confirm my suspicions. In this case there were no vesicles in the ear; they appeared to be confined to the second and third branches of the trigeminal and (?) the cervico-facial.—I am, etc.,

Hove, Feb. 18. G. LLEWELLYN DAVIES.

SIR,—The following brief case report may be of interest, as the clinical combination of herpes zoster and facial palsy described in Case V of Major J. D. Spillane's series was present.

A man aged 73 gave a history of general malaise, anorexia, and abdominal pains for three days, and when first seen had

a typical herpes zoster affecting the Th. 9 segment on the right side. The rash was noticeably profuse, and for several days systemic upset was marked. Pituitrin was given but did not appear to influence the normal course of the disease. Three weeks from the onset of the illness, while there was still considerable reddening and scarring in the rash area, the patient suddenly developed a typical Bell's palsy on the left side. The discomfort of the facial immobility was the only complaint. There was no otitic pain. The skin of the auricle and external auditory meatus appeared to be healthy, and no vesicles were seen on the tympanic membrane; likewise the soft palate and fauces were normal. In view of the history a diagnosis of geniculate herpes seemed probable, facial paralysis being the only clinical manifestation. The patient suffered subsequently from a troublesome post-herpetic neuralgia, but the facial paralysis cleared up uneventfully and without treatment in six weeks.

It is suggested, though the possibility of coincidence cannot be overlooked, that there was in this case an invasion of the geniculate ganglion secondary to a herpetic infection of the ninth thoracic posterior root ganglion. The apparent absence of any involvement of the sensory area of the facial nerve is noteworthy, and bears a close resemblance to Major Spillane's case of combined geniculate and trigeminal zoster. The case appeared to offer clinical evidence supporting the view that some of the usual uncomplicated cases of Bell's palsy are due to herpetic infection of the geniculate ganglion.—I am, etc.,

Sheffield, Feb. 18. F. W. LAURIE

Recurrent Attacks of Herpes

SIR,—Referring to the letter by Surgeon Lieutenant J. F. Burdon (January 25, p. 135) on recurrent attacks of herpes, I would like to draw his attention to an article in the *Zeitschrift für klinische Medizin*, vol. 106, 1927, on the "blister disease" (pusulosis). It is shown in this article that

(*a*) Herpes is an infectious disease *sui generis*.

(*b*) The following varieties—varicella, herpes zoster, herpes corneae, herpes sexualis-genitalis, herpes gestationis, herpes dermatitis herpetiformis, impetigo herpetiformis, papilloma neurotico zosteriforme, hyperidrosis manus, herpes febrilis simplex—are all caused by a neurotropic virus and all belong to the same family of infections. The common denominator of this kaleidoscopic array of phenomena is the blister (pusula).

(*c*) The diseases occur periodically, typically, and in predilected places.

(*d*) The fluid in the blisters is infectious to animals, and when brought into contact with the eye it causes encephalitis.

(*e*) Clinically, these diseases go through the phases of an incubation period, prodromal symptoms, eruptions, healing, and convalescence, as well as periods of contagiousness and immunity.

For treatment auto-inoculation is advisable. In herpes simplex the results are most favourable, in the other forms not so good; but in almost every case the auto-inoculation brings about a change in intensity, frequency, and character of the disease. It is best to inoculate on the second day of the eruption. The clear content of the blister should be rubbed into a scratch or abrasion made beforehand on the forearm. After two days the point of inoculation may become slightly red; between the third and the fifth days it usually shows small blisters. On the fifth day the formerly clear content of these blisters becomes opaque, and on the seventh day the blisters are dried up. On the day following the inoculation the patient feels upset, irritable, and feverish. Neuralgia, muscle-, joint-, and back-aches are normal disturbances. Generally all organs which have once been affected by the disease react with pain or swelling. The previously affected joints may become inflamed for one or two days. After the inoculation headaches with simultaneous affection of the cerebral nerves are common. Symptoms of cerebral disturbances, such as dizziness, sickness, and vomiting, may also occur. Sore throat and laryngitis can be observed in almost every case. If pseudo-angina is present an anginal attack may take place. Sometimes we have pollakiuria, and albumin in the urine but without urinary casts. During the fever period uraturia and phosphaturia may be found. With the disappearance of the fever, usually on the second day, the reactions abate, and on the fifth day everything is normal again.

As is seen, the inoculation causes a fairly serious illness, but the general feeling may be controlled by aspirin-like salicylates. Recovery is rapid and thorough. The results after inoculation are sometimes striking, modifying as it does the condition of the patient and changing the type of the disease. If no blisters can be found one may try an auto-transfusion with 1 to 5 c.cm. of blood at intervals of 5 to 10 days.—I am, etc.,

London, W., Jan. 28. J. PLESCH.

Plasma Infusion in Acute Haemorrhage

SIR,—In their valuable paper (February 8, p. 188) Drs. Black and Ford Smith state that "there is therefore no evidence that plasma infusion in these patients effected any mobilization of red cells from the tissues as it has been claimed to do (Brennan, 1940)." In advocating plasma transfusions in the treatment of haemorrhage (*Journal*, June 29, p. 1047) I reported a series of cases of acute haemorrhage in which rapid infusion of plasma an hour or two later caused mobilization of red cells. While I am aware that some workers do not accept these findings, I submit that if Drs. Black and Ford Smith were unable to find any evidence of such mobilization after the slow infusion of plasma thirty-six hours to six days after haemorrhage, this would not constitute a valid criticism of my observations. In fact, however, of the two cases treated by plasma of which they give the relevant particulars before and shortly after the infusions one—Case 7—shows on their own figures definite mobilization of red cells. Calculated on the venous cell counts it amounts to an increase of no less than 18% in the number of circulating red cells.

Few observers will disagree with the authors' conclusions as to the superiority of blood over plasma in cases of really severe haemorrhage, especially if the latter is of some standing. Indeed, it is difficult to see how serum or plasma could be expected to benefit a patient whose haemoglobin and haematocrit values six weeks after haemorrhage were only 18% and 8% respectively.—I am, etc.,

Leeds, Feb 18. H. J. BRENNAN.

Syphilis and Blood Transfusion

SIR,—Hundreds of thousands of adults in the British Isles are now volunteering as blood donors and all are having a routine blood test to exclude the possibility of syphilis. This seems to be an opportunity for throwing fresh light on what has been an interesting question for many years—the incidence of syphilis in the general population and more particularly the incidence of latent syphilis.

The true incidence will probably never be known unless every person has repeated tests by a serum reaction which is 100% infallible. Various attempts have been made to estimate the incidence. Some authorities have expressed the opinion that it is probably not unduly pessimistic to believe that in the male population of Great Britain more than 5% and perhaps as many as 10% will acquire syphilis before they die. The present rate of fresh infections which receive treatment is about 1.2 per 10,000 per annum. Indirect evidence of incidence has been obtained by investigating the ultimate destination and use of arsenobenzol compounds and from the figures of blood tests carried out as a routine at various antenatal clinics.

It seems improbable that anyone who suspects or knows he has syphilis will volunteer as a blood donor, and cases discovered will be for the most part latent. I should be interested to know if any attempt is being made to co-ordinate all the various results from transfusion centres or approved laboratories. Figures are quoted each year in an appendix to the Annual Report of the Chief Medical Officer of Health of the number of serum tests carried out in approved laboratories for treatment centres, hospitals, and general practitioners, but the percentage positive is not given, and obviously many of the tests must be repeat tests on the same patients. It would be interesting and probably useful if figures from transfusion services could be kept separate.

A further point of interest arises concerning the methods of dealing with those donors who are discovered to have a positive blood test. Is there a uniform policy for dealing with

them? Is he being quietly told that his blood is unsuitable and the matter left at that, or is he being further investigated with all that this may imply—the possible discovery of congenital and marital cases, the possible prevention of miscarriages and production of further congenitals? Admittedly much tact and discretion will be needed in dealing with these cases, but efforts to follow them up would surely be worth while.

Presumably the transmission of syphilis by transfusion will occur but rarely if most of the blood is being converted into plasma. It is conceivable, however, that there are centres where a register is kept and donors are called upon to give whole blood urgently—possibly weeks after their blood tests have been done. These donors may have contracted syphilis in the meantime and know nothing of it or be in the incubation stage. Dr. J. A. W. McCluskie (*Journal*, February 11, 1939, p. 264) drew attention to the possible danger of transmission of syphilis by transfusion in the incubation period and the possible medico-legal consequences. He also suggested a possible safeguard—the addition of 0.45 gramme of neosalvarsan to the transfused blood.—I am, etc.,

Rotherham, Feb. 6. R. C. WOFINDEN, M.D., D.P.H.

Bipp in Acute Osteomyelitis

SIR,—Probably the most important contribution to the efficient treatment of infected wounds during the last war was the introduction of the bipp method by Prof. Rutherford Morison. During the past twenty years this method seemed to lose favour with many of the post-war generation, who, perhaps, like the Athenians of old, were searching for some new thing. Fortunately Morison's bipp treatment has been powerfully advocated and his technique clearly explained in recent issues of the *Journal* by Dr. William Mackenzie (December 28, p. 917), Prof. R. J. Willan (January 11, p. 62), and Sir Charles Gordon-Watson (February 8, p. 211). May I give my testimony as to its great value in the treatment of acute osteomyelitis.

In June, 1921, a boy of 6 years was admitted to the East Suffolk Hospital under my care. He was very ill; temperature 105° F., pulse 160. The left leg was greatly swollen, inflamed, and acutely tender; there was no involvement of knee- or ankle-joint. A tourniquet was applied above the knee. This is of primary importance to avoid blood infection during the operation. A free incision was made on the inner side of the tibia for the whole extent of the diaphysis. The periosteum was completely stripped from the whole of the diaphysis by a quantity of pus, from which a culture was taken.

I thought it possible that even when the outside of the shaft was bathed in infected pus and the medullary canal similarly infected, the actual dense bony tissue might retain its vitality if completely disinfected on its outer and inner surfaces, and if the surface of the periosteum were also completely disinfected. The pus between the shaft and periosteum was first washed away, and then the surfaces of the bone and periosteum were thoroughly scrubbed with gauze swabs soaked in carbolic lotion 1 in 20, and then with methylated spirit, and finally with ether; layers of sterile gauze were packed between the periosteum and the shaft. Next the medullary canal was laid open for the whole of its length, the marrow, which was infiltrated with pus, was scraped away, and the interior of the canal thoroughly scrubbed with carbolic lotion, alcohol, and ether. Finally strips of gauze saturated with bipp, from which the excess was squeezed out, were placed between the periosteum and bone, and the medullary canal was packed with similar strips. A sterile dressing was then applied and firmly bandaged, and the tourniquet removed.

Next day, when the dressing, which was soaked with blood and serum, was removed, all swelling, redness, and tenderness had disappeared, the leg was of the same size as the other, the temperature and pulse were normal. The strips of gauze were removed on the third day. The wound healed without suppuration except for a small sinus on the metaphysis, which continued to discharge a little pus for several weeks until a very small sequestrum came away and the sinus closed. During this time there was a slight febrile reaction. *Staphylococcus aureus* in pure culture had been grown from the pus, and a vaccine was given. The diaphysis maintained its vitality; there was no sequestration or growth of new bone. A photograph of the two legs taken five years later showed complete similarity, except for the scar of the operation, and a radiograph of the left leg showed an absolutely normal tibia, except for the absence of a medullary canal (*Clinical Journal*, February 19, 1930).

I was not aware at the time of the operation that the original focus, from which infection spreads between the periosteum to the shaft and then to the medullary canal, is to be found in the cancellous tissue of the metaphysis. If that had been opened and treated with bipp the whole limb might have healed within about three weeks.—I am, etc.,

Worthing, Feb. 15. HERBERT H. BROWN.

Anuria after Sulphapyridine

SIR,—The case of fatal anuria following sulphapyridine in pneumonia reported by Major F. R. Fletcher (February 15, p. 242) is very interesting. I am, however, chiefly concerned in the treatment.

Decapsulation of the kidney is only a half-hearted procedure, and pyelostomy is useless unless the ureters are obstructed. The only curative operation is nephropyelostomy. The kidney should be incised along the convex border, and a tube inserted down to the pelvis. The kidney should then be lightly sutured, just enough to arrest haemorrhage. In the case reported pyelostomy was performed only on one side. I would like to know why.—I am, etc.,

London, W.1. F. MACG. LOUGHNANE.

Sterilization of Instruments

SIR,—There are one or two points suggested by Dr. W. N. Leak's letter (February 15, p. 254) on the sterilization of instruments which may interest the many who nowadays are helping in the diphtheria immunization campaign. When the empty and sterile needle is put "on the vacant nozzle of the operator's syringe" it will be necessary, before making an injection, to fill the needle with the inoculum by gentle pressure on the piston until fluid begins to emerge from the point. If this is not done, (1) air, possibly contaminated with organisms, will be injected ahead of the inoculum, and (2) the patient will not receive the full dose.

There are times when one has to carry out injections without an assistant and in unhygienic surroundings. May I recommend once more (*Publ. Hlth.*, August, 1940, **53**) the use of a spirit lamp, the needle being passed through the flame after each injection, and the stopper of the bottle flamed before each replenishment. Experience comprising thousands of injections in clinics, schools, halls, bed- and sitting-rooms kitchens, and even—shades of Lister—by the roadside, has shown that this method, combined with iodine sterilization of the skin, is safe and well worthy of trial.

Recently, having all but exhausted one of the 25-c.cm. bottles of A.P.T. supplied by the Ministry, I submitted the dregs to examination by an expert bacteriologist. Culture under both aerobic and anaerobic conditions showed that the residuum was sterile. This bottle had been in regular use for a period of more than three weeks. The majority of the injections were 0.1 c.cm., the remainder 0.3 c.cm.; the syringe held 1 c.cm.; and quite half the injections were given singly during house-to-house visits among the poorer classes, thirty at a time being a very unusual "bag." This culture experiment is encouraging testimony to the efficiency of both the technique employed and the method of preserving the antigen.—I am, etc.,

Cross-in-Hand, Sussex, Feb. 19. H. LYNDHURST DUKE.

Permanganate for Snake Bite

SIR,—In your September 28, 1940, issue (p. 424) appears an annotation on snake bite. From time to time this subject crops up, and writers not only warn us of the uselessness of permanganate of potash but also point out its dangers. It has been my lot to have attended at least a dozen cases of undoubted snake bite in human beings and five in dogs, so far as I can remember, and one horse, both in Africa and in Australia. My practice has been to make as strong a solution

as I can in cold water and inject several syringe loads under and around the punctures. I have always feared gangrene, but considered that a patch of gangrene was better than a dead child. I have never seen any harmful effects from the injections, but rapid improvement where symptoms were bad. I have never seen a fatality in these cases.

About 1903 Sir Lauder Brunton did a good deal of research in this direction, and I became acquainted with his work in a paper called the *Medical Review*. It would be interesting for anybody who has access to these papers to look up his researches, because it does not seem feasible that a man of his qualifications and ability should be entirely wrong. This matter is of vital importance to people living in country places where snakes are prevalent and anti-venom unobtainable for some considerable time, but where permanganate of potash is in every home. All the patients seen by me had been bitten on the hand or bare leg, so there was little chance of the venom being wiped off on the clothing.

For the satisfaction of many, it would be advisable to refer to the work of Sir Lauder Brunton and to publish any experimental work that had been done in relation to permanganate of potash and snake venom and to check his results in comparison with modern research. Let us have something more definite than the remark that "permanganate of potash is not considered of any use nowadays." We folk who live among snakes feel that it is up to those who make these statements to give us concrete proof, and as our experiences are in its favour it is not likely to be discarded till that is forthcoming.—I am, etc.,

Ballarat, Victoria, Nov. 27 SYDNEY PERN

Pellagra in Great Britain

SIR,—Pellagra is generally considered to be a rare disease in this country. It is certainly rarely recognized, and I suppose few doctors except those in mental hospital practice have diagnosed many cases. My experience is probably unusual. I have seen three fully developed cases of pellagra in my own (general) practice in the past five or six years. One of these is reported in full elsewhere (*Edin. med. J.*, 1940, **47**, 81).

Whether it is rare or not, I have the impression that there must be quite a few unrecognized cases of this disease in the country. The matter is one of importance, since we now have at our command a specific cure in nicotinic acid. There are few things in the whole range of therapeutics so dramatic and so satisfactory to patient and doctor as the speedy recovery (from a serious and often fatal disease) of pellagrins when given an adequate dosage of nicotinic acid. Cure is a matter of days, sometimes almost of hours. Severe mental symptoms, such as mania, may disappear in twenty-four hours and the dermatitis and buccal lesions in a few days. In diagnosis it is useful to remember the three "D's" of the pellagra triad—diarrhoea, dermatitis, dementia.

Apart from the full-blown pellagra syndrome, there must be many cases of minor deficiency of nicotinic acid which would benefit from the exhibition of this substance. For instance, I have under my care at present a young man whose sole complaint is a very unpleasant tingling of the tongue. Nicotinic acid abolishes this symptom, which, however, recurs on omitting the treatment. Prof. H. Gordon Campbell (February 15, p. 262) reports successes in cases of "blisters of the lips."

Incidentally, it seems a pity that the Government is introducing only one factor (B_1) of the important vitamin B complex into the new loaf, and a greater pity that a more natural type of vitamin supply in the form of a wholemeal loaf should not be more widely available and consumed. There is something Gilbertian in our policy of first removing this vitamin from the wheat and then replacing it (in part) at great expense.

Recently I have been using nicotinic acid amide in the maintenance care of a case of pellagra, and find it well tolerated and possibly more effective in the prevention of symptoms.

It would be interesting to know if pellagra is occurring with any frequency in other parts of the country. There is a possibility of an increase of this and other deficiency diseases owing to war restrictions in diet.—I am, etc.,

Edinburgh, Feb. 19 DOUGLAS S. ROBERTSON, M.D.

Nurse Anaesthetists

SIR,—Anaesthesia has always been the most neglected of all branches of medicine. Although the patient's comfort and even his very life may depend upon good anaesthesia, there are still far too many places where this fact is utterly ignored, where any old thing will do provided that it is easy and cheap.

There are just a few places in the world (such as the University of Wisconsin) where real enthusiasm and encouragement exist. These have led to very great technical advances, such as the introduction of cyclopropane. Until recently, however, England, though perhaps possessing the highest average level of attainment, had no outstanding school, no Mecca to attract anaesthetists from other countries. That want has been supplied at Oxford by the generosity of Lord Nuffield, with the result that Oxford now compares favourably with the first-class American centres of anaesthesia work. I am sorry to see that Cambridge, far from emulating the progressive and enlightened spirit of the rival institution, is proposing to take a retrograde step and institute that bane of the second-rate American medical school—the nurse anaesthetist—which Canada has been wise enough to prohibit after extensive trial. Not satisfied with ignoring modern progress (and the law relating to covering unqualified practice), Cambridge is to put the clock back and give up all hope of further advance. There is a similar school of thought in India at the present time—a desire to abolish Western science and return to the era of the totem pole and the medicine man. But I never expected that Cambridge would enter this unholy competition.

It is true that technicians can be trained to give anaesthetics competently by certain methods, but this does not make them into anaesthetists. Similarly technicians could easily be trained to remove appendices, but that would not make them into surgeons. What anaesthesia needs is not deliberate retrogression but deliberate encouragement, for there is far too much bad work done already, even by men capable of better things. I personally know of two recent cases where patients were killed by an experienced man simply because of this crazy surgical insistence on cheap anaesthesia, which is so widespread as to be almost universal.

If this proposal is adopted I for one will cease to use certain Cambridge degrees which I previously thought to be of some value. I am not conceited enough to think that this will affect the university in any way, but it will at least clear my own conscience by dissociating me entirely from a reactionary policy which is in such striking contrast to the enlightened and progressive spirit of Oxford.—I am, etc.,

W. STANLEY SYKES.

"India Wants Medicine, Not Magic"

SIR,—It is exceedingly regrettable that you should have published in the correspondence columns of the *Journal* of August 24, 1940 (p. 268) Dr. M. N. Pai's letter without attempting to verify the various allegations made therein. I am only concerned with the attack made upon the quality of the equipment and qualifications of the staff of the new Stanley Medical College and the Government Rayapuram Hospital, Madras, to which it is obviously referring.

1. Among the various misrepresentations I would like to point out that it is a grossly incorrect statement that the new College is staffed with professors possessing mediocre qualifications. The College is staffed with professors possessing high academic qualifications and considerable teaching experience. In every instance best-qualified professors available from the ranks of the Madras Medical Service and from the independent medical profession have been chosen. No professor with mediocre qualification has been taken in preference to competent Indians with British qualifications available on the spot.

2. No lady nurses were discharged; on the contrary, the nursing staff has been considerably increased.

3. Numerous additions to house the various departments of this teaching institution have been made to the Government Rayapuram Hospital, and also new buildings of the Stanley Medical College are nearing completion, having been con-

structed with due regard to all the requirements of a rapidly growing up-to-date and well-equipped scientific teaching institution.

I enclose herewith: (1) a detailed statement showing the staff of the Government Rayapuram Hospital and Stanley Medical College with their qualifications; (ii) a statement showing the accommodation available and the number of patients received in the Government Rayapuram Hospital, both out-patients and in-patients, as well as in the various special departments of the hospital which afford opportunity for clinical teaching; (iii) a statement of the existing nursing staff as compared with staff available before the inauguration of the Stanley Medical College.

I would like to add that the institution, which at present is recognized only for the purpose of teaching the pre-registration and the first- and second-year subjects, is to be shortly visited by the Madras University Commission and its requirements assiduously studied. Further additions and improvements to the equipment and staff are under consideration by Government.

I trust that you will give wide publicity to the above, as otherwise members of the medical profession, particularly outside India, are likely to have grotesque and distorted ideas of the nature of medical relief available in this country and give an impression abroad that India is a land of magic and quackery.—I am, etc.,

G. DINKER RAU, M.D.,
Madras, Nov. 18, 1940. Principal, Stanley Medical College.

An American Surgeon's Assurance

SIR,—I think that readers of the *British Medical Journal* will be interested in the subjoined extract from a letter received from the U.S.A. this morning. It was written by a surgeon and dated January 7, when the Lease-and-Lend Bill was in its infancy, and it indicates how widespread at that time was the desire to help Britain to the utmost.

> "You, I mean England, is having enough trouble. We are going to do everything to see that England does not fall. To you it may seem slow. A few months more will make a difference that even you will not believe. You will read of opposition, but it is a small minority—but vociferous."

—I am, etc.,

London, W.1, Feb. 18. ARNOLD LAWSON.

Greetings from Mexico

SIR,—We have received in the offices of the *Gaceta Médica de México*, organ of the National Academy of Medicine, the Centennial Number of the *British Medical Journal*, for which we thank you profoundly. As Editor of the *Gaceta*, it gives me great pleasure to send you my sincere and cordial congratulations upon the centenary just celebrated, which marks an epoch in the history of the world medical press. It is my hope that your illustrious *Journal* will continue its existence as, in the words of Sir D'Arcy Power, "the representative organ of the medical man in general practice." May the *British Medical Journal* continue working, as in 1840, for "the maintenance of the honour and respectability of the medical profession."

This noble programme, which has been maintained and has gathered strength for 100 years, is an example to all the medical papers of the world, which I believe that they should follow, as they should also bear in mind what the founders of the *British Medical Journal* said in 1840 when they affirmed that scientific questions and practices related to medicine should be considered "not merely in the light of personal struggle, on the part of the medical man, for his own individual rights and privileges, but also as part of the system of a wise and effective form of government, in which the health and lives of the people become equally objects of attention with the regulation and preservation of the rights of property." Such wise and altruistic rules of conduct acquire in this painful epoch a vibrant reality and are a clear declaration of the great democratic spirit of England, which has always fought and continues to fight for the preservation of the fundamental rights of man, winning by its extraordinary example of fortitude and confidence the admiration of the whole civilized world.

Please receive this testimony of the cordial sympathy and the justified admiration of the *Gaceta Médica de México*, which celebrated its 75th anniversary in 1939, and our sincere wishes that the *British Medical Journal* should continue to bear the standard of medical ideals and, above all, that England, the mother of human liberties, should emerge from these calamitous times victorious in the struggle for the salvation of democracy and humanity. And as an objective demonstration of these sentiments, I ask you to receive henceforth the *Gaceta Médica de México*, which we shall be very pleased to send you, so that it may occupy a place among the other numerous medical publications that you certainly receive from all parts of the world.

I take advantage of this opportunity to assure you, Mr. Editor, of my attention and consideration.

DR. ALFONSO PRUNEDA,
Dec. 11, 1940. National Academy of Medicine, Mexico.

*** It gives us much pleasure to publish this translation of a letter from a brother Editor. We thank Dr. Pruneda for his congratulations and reciprocate his good wishes.—ED., *B.M.J.*

The Flannel Hood Respirator

SIR,—I feel obliged, very reluctantly, I admit, to refer to the appreciation of the late Colonel Sir William Horrocks in your issue of February 15 (p. 258). Sir Leonard Hill, the author, makes an error in supposing that Sir William Horrocks was the designer of the flannel hood respirator for the use of the British Army. This was suggested to the Central Laboratory at G.H.Q. by Captain Cluny MacPherson of the Newfoundland Forces (Medical Corps) as a type of respirator that might do. The Central Laboratory sent Captain MacPherson over to London with his respirator, and I myself was present when he arrived and showed his hood to Colonel Horrocks. I am quite sure that Colonel Horrocks went out "and ordered the flannel on his own responsibility." Such a course was quite in keeping with his character and just like him. He was one of the most charming men and one of the least likely to take up an attitude of waiting for something that seemed to him important. But that he designed the hood respirator is not true. Probably Sir Leonard Hill got the impression that he did so, but the facts are as stated.—I am, etc.,

S. LYLE CUMMINS,
Feb. 18. Colonel (R.P.), late R.A.M.C.

MOBILE PHYSIOTHERAPY UNIT FOR THE RED CROSS

The first mobile physiotherapy unit for the treatment of men in the Forces was presented by the Chartered Society of Massage and Medical Gymnastics to the War Organization of the British Red Cross and Order of St. John on February 21. Lord Horder, president of the Chartered Society, in making the presentation, said that in July last a member of the Society's council, Miss B. A. Wilson, brought forward the proposal that as a contribution to the nation's war effort subscriptions should be collected for the provision of mobile physiotherapy units. Her plan was that such units should be mounted in a small motor van so that they could be brought in any district to convalescent homes and hospitals which were not large enough to have a department of physical medicine. The proposal was adopted, and this first unit was subscribed for in the town and district of Sevenoaks, which name appeared on the van with the Society's coat of arms. The unit, which is to be staffed by a masseuse and a Red Cross driver, contains all the apparatus for giving electrical and light treatments, including infra-red and ultra-violet rays and paraffin wax baths, but apparatus for diathermy and high frequency is absent, the use of these methods being at present prohibited. The various apparatus and its accessories are mounted on four trolleys, which can be wheeled into the hospital. The unit was accepted on behalf of the War Organization of the two Societies by Sir Philip Chetwode, who said that it would be stationed in Warwickshire. It is the desire of the Chartered Society to provide a fleet of such units for use in all parts of the country, and later with the Forces abroad if necessary.

Obituary

PROFESSOR WILLIAM BULLOCH

M.D., LL.D., F.R.S.

William Bulloch was born at Aberdeen on August 19, 1868, the younger son of the late Mr John Bulloch. He studied medicine in Aberdeen University, being a student of Hamilton, graduated M.B., C.M. with the highest honours in 1890, and took his M.D. with similar honours in 1894, winning in the same year the Struthers Gold Medal and Prize in Anatomy. For one year after qualification he was assistant to a doctor in practice, but, feeling that he "had done nothing save shown some kindness," he "decided that there must be something to learn in the world." With £100 and no knowledge of German he went by cargo-boat to Hamburg and thence to Leipzig, where he was accepted as a voluntary assistant by Birch-Hirschfeld. He then went to Vienna to learn practical medicine, studying under Politzer, Caposi, and others. He returned by cargo-boat to Aberdeen, and that night met his fellow-student Arthur (now Sir Arthur) Keith, who persuaded him to come with him next day to try his fortune in London. He was told on arrival that there was no prospect for him unless he had the Conjoint qualification, but he was made assistant to David Ferrier at King's College, and was later appointed Assistant to the Professor of Pathology of University College, Victor Horsley, who enabled him to study under Émile Roux in Paris. He was a pupil also of Salomonsen of Copenhagen. From July, 1895, to June, 1897, he was bacteriologist in charge of the antitoxin laboratories of the Lister Institute at Sudbury. He was elected bacteriologist to the London Hospital on June 27, 1897, became Goldsmiths' Company Professor of Bacteriology (London University) in the London Hospital Medical College in 1919, retired in 1934, and was immediately appointed Consulting Bacteriologist to the London Hospital and Emeritus Professor of London University. After his retirement until the outbreak of war he still came daily to work in his old room, looking after the sterility of the London Hospital catgut. He was elected F.R.S. in 1913 and made LL.D. Aberd. in 1920. He was Horace Dobell Lecturer to the Royal College of Physicians in 1910, Tyndall Lecturer to the Royal Institution in 1922, and Heath Clark Lecturer in 1936.

Bulloch was a very hard and methodical worker. For years, until his services were required on various committees, he worked at the London Hospital from 10 a.m. to 4 p.m., read in the library of the Royal College of Surgeons until it closed, had supper at home, and then read till bed-time: on Sundays he read until about 6 p.m., then dined in a restaurant and ceased work for the day. He was endowed with an astonishing memory and, like his elder brother, John Malcolm, LL.D. (1867–1938), inherited great literary ability from his grandfather, John Bulloch (1805–82), and his father (1837–1913). His great learning included general history as well as his own subject. By visits to congresses he extended his knowledge of foreign workers and languages, and came to know personally every pathologist of note. Paul Ehrlich was a particular friend. His greatest characteristic was the high standard of accuracy he set himself and expected of others. This made him a severe critic and had a profound influence upon everyone in the London Hospital. Although he appeared to remain isolated in his own department he had an uncanny way of knowing everything that was going on, and all workers, whether bacteriologists, morbid anatomists, physicians, or surgeons, knew that any slipshod work, writing, or speech would be severely criticized: even a lay member of the staff would take care that anything he wrote escaped Bulloch's criticism. All learned that every reference or quotation must be searched to its source, and an accurate transcript be made of it and the title of the book or paper from which it came. Any faulty reference was immediately recognized by him and shown up. His quick mind, accurate knowledge, and orderly method of thought made him speak spontaneously as clearly as he wrote, and he was a formidable witness in courts of law. Of the old school, he did his practical work with his own hands, and was remarkably skilled in all branches of pathological technique.

At the London Hospital he lectured on bacteriology, general pathology, and at one time more advanced bacteriology for the diploma of public health. The lectures were crowded with accurate information, and his personal knowledge of foreign workers gave his descriptions of their experiments and discoveries a remarkable reality. It was difficult to believe that Bulloch had not been a spectator when he gave his full and dramatic account of the biting of the boy Joseph Meister by a mad dog, the rush to Pasteur, and the anxiety and excitement over the treatment until its success was proved. He was an inspiring teacher. Relatively few graduates worked with him as assistants or pupils, but in a list of seventeen which the writer has obtained are E. E. Atkin, T. H. C. Benians, S. L. Baker, Charles Bolton, P. Fildes, M. Greenwood, J. C. G. Ledingham, J. McIntosh, J. McCunn, H. P. Parker, R.N., H. M. Turnbull, F. M. Twort, and G. T. Western.

Bulloch published in British and German journals at least thirty papers embodying original research. The first was in *Brain* in 1892, and in 1894–5 there were two further contributions to neurology, one to morbid anatomy with Georg Schmorl, and one to dermatology with G. Pernet. His first bacteriological paper was on *Strep. pyogenes* in 1896. After that all contributions were to bacteriology, serology, immunity, and the treatment of bacterial disease, except two further dermatological papers, with Pernet (1896) and with N. W. Holmes (1902), and a paper with J. H. Sequeira (1905), "On the Relation of the Suprarenal Capsules to the Sexual Organs"—a milestone in endocrinology. His last two bacteriological papers were concerned with the viability of bacteria in antiseptic solutions, both in 1928. He also wrote upon the teaching of pathology in Great Britain (1903), on the use and abuse of scientific medical literature (1921), and foot-and-mouth disease in the sixteenth century (1927). Further, he wrote appreciations of Pasteur, Spallanzani, Lewis, and Cobbold (1922), Lister (1927), and Robert Koch (1932), and obituaries of Emanuel Klein (1925), Charles Creighton (1928), Haffkine (1931), Kitasato (1931), Émile Roux (1934), and Theobald Smith (1935). These publications upon scientists show clearly his thoroughness, accuracy, and literary skill. A notable example of his contributions to books is "The Pathology, Bacteriology, and Specific Treatment of Pulmonary Tuberculosis" in Allbutt and Rolleston's *System of Medicine*, vol. v, 1909.

The following are larger works. He edited and contributed to "Studies in Pathology, written by Alumni to Celebrate the Quatercentenary of the University of Aberdeen," Aberdeen, 1906. He contributed in 1909 the articles on diabetes insipidus, pulmonary tuberculosis, chronic hereditary trophoedema, angioneurotic oedema, hereditary malformation of the genital organs, and hermaphrodism to the *Treasury of Human Inheritance*, Parts 1 to 3, and, with Paul Fildes, to Parts 5 and 6, 1911, the acknowledged classic on haemophilia. His Horace Dobell Lecture, delivered before the Royal College of Physicians of London on November 10, 1910, entitled "The Problem of Pulmonary Tuberculosis, considered from the Standpoint of Infection," was published by the School Press, London, in 1911. With the late Sir F. W. Andrewes and others he wrote *Diphtheria: Its Bacteriology, Pathology, and Immunity*, published by the Medical Research Council in 1923. He contributed to *A System of Bacteriology in Relation to Medicine*, published in nine volumes, 1929–31, by the Bacteriological Committee of the Medical Research Council, of which he was chairman. His unique work with Lampitt and Burhill on *The Preparation of Catgut for Surgical Use* was published in 1929 in the Special Report Series No. 138 of the Medical Research Council. In 1938 he published *The History of Bacteriology*, based upon his Heath Clark Lectures of 1936—an outstanding contribution to medical history.

In the above no mention has been made of many important contributions to medical science published independently from his laboratory by his pupils, particularly Fildes and McIntosh.

He was elected to numerous administrative posts. He was an original member of the Medical Research Committee (later, 1920, Council), member of the Government Committee on Foot-and-Mouth Disease, member of the Executive Committee of the Imperial Cancer Research Fund, member (1918), and later (1932 to his death) Chairman, of the Governing Body of the Lister Institute, member of the Committee of the Beit Memorial Trust, Consultant to King Edward VII Sanatorium, and President of the Section of Pathology of the Royal Society of Medicine (1917). From 1925 to 1935 inclusive he was Honorary Librarian of the Royal Society of Medicine, and was made an Honorary Fellow of that society in 1940. He examined in the Universities of London, Leeds, and Liverpool, and for the Royal College of Veterinary Surgeons, and was induced to reappear as an examiner when the Conjoint Board first introduced an examination in pathology.

Bulloch had a great sense of humour, could enjoy a joke against himself, was an inimitable raconteur, and inherently sociable: he had a remarkable aptitude for getting to know personally and remembering everyone with whom he came in contact, however humble. Those who worked with him will never forget his great kindness and generosity. In 1923 he married Irene Adelaide, widow of Mr. A. A. Baker, and the happiness that his marriage brought him was obvious to his friends. Several years before he retired his colleagues were dismayed to see gradually increasing signs of paralysis agitans. He did not, however, allow his illness to interfere with his work. In 1939 he learned Italian in order to make better progress with another work upon Spallanzani, and last Christmas he sent to the publishers a second edition of his classic upon surgical catgut. In the last eighteen months his condition deteriorated rapidly. He was admitted to his old hospital on February 9, 1941, and died on the 11th.

We offer our deep sympathy to his widow and her daughter.

H. M. T.

THE REV. S. D. BHABHA, M.D.

The Rev. Shapurji Dadabhai Bhabha died on January 3 at the age of 86. He was born in the city of Surat of devout Zoroastrian parents, and claimed descent from an old noble Persian family dating back to the thirteenth century. At the age of 14 he was sent to the Irish Presbyterian School, and in 1874 became a convert to the Christian faith.

He came to Glasgow in 1876 and studied theology and medicine at the same time. He qualified L.R.F.P.S. and L.M. in Glasgow in 1880, took his L.S.A. in 1883, and M.D. Brux. in 1884. He was later ordained priest in the Syrian Church at St. Mark's Monastery, Jerusalem. He settled in New Cross over forty years ago, and was connected with medical mission work, especially the East End Mission to Jews, besides undertaking an extensive private practice in his own neighbourhood. He became a member of the B.M.A. in 1881 and was representative of the Greenwich and Deptford Division from 1913 to 1937 and was chairman of the Division in 1925–6. He took a very keen interest in the work and meetings of the Representative Body, and was very delighted when he was able to complete his "jubilee" as representative at the Belfast Meeting. He was an enthusiastic upholder of the rights and responsibilities of the profession, and regarded with stern disfavour any falling away from the highest principles of medical conduct and ethics. His health began to fail soon after the Belfast Meeting, and a young relative, a great-niece, came over from India to care for him.

Dr. Bhabha inspired a great affection amongst his patients, and many visited him during his last illness. The present war was a great blow to him, but he never lost courage, and refused to leave his home in spite of the ferocity and noise of the air attacks. His was a simple nature, combining the qualities of priest and physician, and his courage and fortitude, his love for his fellow man, and his hatred of evil were an inspiration to those around him.

Dr. WILLIAM KIRKPATRICK, who died on February 8 at Sherborne, aged 79, was one of the sons of the Rev. George Kirkpatrick, rector of Castlepollard, Co. Westmeath, Ireland. Like his brother, Lieut.-Colonel Henry Kirkpatrick, I.M.S. (ret.), he was educated at Marlborough and at Trinity College, Dublin. He had a distinguished undergraduate career, winning the senior classical gold medal and the senior Berkeley gold medal in Greek in the year 1885, and was senior classical scholar. After graduating M.D., B.Ch. in 1889, he practised at Stourbridge, Worcestershire, until the last war, when he was placed in command of the military hospital there with the rank of lieutenant-colonel, R.A.M.C.T., and was twice mentioned in dispatches. Dr. Kirkpatrick practised at Sherborne from 1922 until 1937; he was for eleven years a member of the Urban District Council, and its chairman in 1928.

Dr. ERNEST FREDERICK LIONEL DE JERSEY, formerly surgeon to the Victoria Hospital, Guernsey, died on February 11. He was born in May, 1872, at Lymington, Hants, son of the Rev. C. C. de Jersey, and after schooldays at Wimborne Grammar School and Elizabeth College, Guernsey, entered Glasgow University as a medical student, taking the Scottish triple qualification in 1897 and the M.B., Ch.B. a year later. Before settling in practice in Guernsey he had been senior assistant medical officer at the Burntwood Asylum, Lichfield, and house-surgeon to the Morpeth Dispensary and to the Royal Berks Hospital, Reading. During the last war he served with the rank of major R.A.M.C. as senior medical officer to the Royal Guernsey Militia Home Service. Dr. de Jersey joined the British Medical Association in 1906 and was chairman of the Guernsey and Alderney Division in 1926–8. He had practised at Surbiton, Surrey, in more recent years.

We regret to announce that Dr. CLAUD BUCHANAN TICEHURST of Appledore, Kent, died at the Royal East Sussex Hospital, Hastings, on February 17. He was the youngest of the three medical sons of Dr. Augustus R. Ticehurst, J.P., of St. Leonards-on-Sea, who all went from the same house at Ton-

bridge School to Cambridge University and thence to Guy's Hospital. He graduated B.A. in the Natural Sciences Tripos, and while a clinical clerk at Guy's wrote jointly with Dr. Herbert French a paper on the relation of traumatic diabetes insipidus to glycosuria which was published in 1906 in the *Guy's Hospital Reports*. He qualified M.R.C.S., L.R.C.P. in 1907 and took his M.A. and B.Ch. degrees at Cambridge, and then served as house-physician and resident obstetrical officer at Guy's. After further experience of hospital work and in general practice he entered a partnership at Lowestoft, and was appointed assistant surgeon to the Lowestoft and North Suffolk Hospital. Dr. Ticehurst joined the British Medical Association in 1911 and was chairman of the North Suffolk Division in 1926-7. A year later, on leaving Lowestoft to set up in practice at Appledore and Ham Street, near his old home, he was elected consulting surgeon to the North Suffolk Hospital. Like his eldest brother, Mr. Norman F. Ticehurst, F.R.C.S., author of the *History of the Birds of Kent* and joint author of *A Handbook of British Birds*, Claud Ticehurst was a keen member of the British Ornithological Union and Club and had edited the Society's *Transactions*; he was also a Fellow of the Royal Geographical Society.

Dr. WILLIAM TAYLOR DOYLE ALLEN, a member of the British Medical Association for nearly forty years and chairman of the Liverpool Division in 1922, has died at Heswall, Cheshire, where he lived in retirement after practising for many years at Mount Pleasant, Liverpool. He studied medicine in Dublin at the School of the Royal College of Surgeons, and graduated M.B., B.Ch., and B.A.O. of the Royal University of Ireland in 1895. He was then for some time resident medical officer to the Liverpool Parish Infirmary, and acted as local medical officer for the L.M.S. group of hotels and as honorary physician to the Liverpool School for the Blind. For four years during the last war Dr. Allen was medical referee to the local War Pensions Committee.

Dr. ROBERT CECIL TURLE EVANS has died at the age of 69 at Herne Bay, where he practised for twenty-seven years and closely associated himself with many of the town's institutions and activities. After studying in London University College and Hospital he qualified as L.S.A. in 1906, and two years later graduated B.Sc., M.B., and B.S.Lond., taking also the English Conjoint diplomas and the D.P.H. For some years Dr. Evans had been a demonstrator in chemistry at St. Bartholomew's Hospital, and coached students in chemistry and physics at a house in Bloomsbury. He began practice at Herne Bay in 1908, and in 1915 joined the R.A.M.C., serving with a temporary commission in Malta, Egypt, Mesopotamia, Persia, and India. Returning to civilian practice in 1920, Dr. Evans did good work as surgeon to the local division of the St. John Ambulance Brigade, and was medical officer to the Herne Bay Infant Welfare Centre until his retirement from practice in 1932. Three of his children are members of the medical profession.

The late Dr. JULIUS BARNET SINSON graduated with honours as M.B., Ch.B. of Leeds University in 1911 after holding several scholarships. The son of a Rabbi now a venerable and beloved figure in the religious life of the Leeds community, he was a fine type of medical practitioner. Dr. Sinson, who joined the British Medical Association in 1920, had been in general practice in Newcastle-upon-Tyne for twenty-two years, and his passing has evoked demonstrations of sympathy and regret from among his many patients. During the last war he served with the rank of captain, R.A.M.C.

The following well-known foreign medical men have died: Dr. OLIVER THOMAS OSBORNE, emeritus professor of clinical medicine at Yale University School of Medicine, aged 77; Dr. MAX NADOLECZY-MILLIOUD, at Zurich, formerly professor of otology and laryngology at Munich; Dr. KURT HULDSCHINSKY, the German-Jewish discoverer of the ultra-violet-ray treatment for rickets, at Alexandria; Dr. VITTORIO PUTTI, the orthopaedic surgeon of Bologna; Dr. PHILIPP BROEMSER, professor of physiology and rector of the University of Munich, formerly professor of physiology at Basle, aged 54; Dr. JOHN AUGUSTUS HARTWELL, emeritus professor of clinical surgery at Cornell University Medical College and president of the New York Academy of Medicine, aged 71; and Dr. KARL HEDÉN, a Stockholm dermatologist, aged 59.

Medico-Legal

HYSTERIA CAUSED BY SHOCK WITHOUT PHYSICAL INJURY

At the February Norwich Assizes, before Mr. Justice Atkinson, Mrs. Esther Englestown brought an action against two defendants, Mr. G. Shead and Mr. H. Hardy, for negligence. It was stated by her counsel, Sir Charles Doughty, K.C., that in February, 1937, a motor-car driven by Mr. Shead collided with a lorry driven by the second defendant with the result that the car left the road, crossed the footpath, and came to a standstill in the garden of a house. Mrs. Englestown had to jump aside to avoid the car, but she was never touched by it and sustained no organic injury. She was greatly frightened, lost her nervous control, and her state had gradually deepened into one of profound hysteria, so that now, four years after the accident, she was practically confined to bed, complained of severe pains in various parts of the body, and was quite unresponsive to medical treatment. She was 49 years of age.

The Medical Evidence

Dr. J. H. Owens of Long Stratton testified that he was called in to see the plaintiff about three weeks after the accident, and had attended her ever since. She was highly emotional and had been getting worse. She complained especially of pains in the leg, and on any attempt to move it or touch it she cried and behaved in a hysterical manner. She stated that the thought of the motor-car coming towards her was always present to her mind. He considered she was not malingering, but that her condition was functional. He had supplied her with medicine to steady her nerves and enable her to sleep, and in June, 1939, he saw her in conjunction with the medical superintendent of the county mental hospital, who advised treatment in an institution, to which, however, she would not submit. Her present condition was one of extreme nervous hysteria with hyperaesthesia of the limbs. Since the accident he had paid her 183 visits and supplied 230 bottles of medicine, and his bill, with four consultations with other medical men, came to £132 7s. In reply to the judge he said that he agreed that institutional treatment was desirable, but he was not sure that the mental hospital was the most suitable place. The medical superintendent, however, had "guaranteed" to cure her within a matter of months.

Dr. B. B. Morgan, honorary physician, Norfolk and Norwich Hospital, said that he saw the plaintiff on January 18 last. She complained of pain in the side and leg. She had two emotional attacks while he was present, one when someone mentioned the word "motor-car" and the other when he was testing her plantar reflex. He found no evidence of organic disease. She held her hands curiously with the tips of the fingers tightly pressed together, the palms concave, and the wrists slightly extended; her right leg was pressed against the shin of the left. He thought treatment in a mental hospital in the wing set apart for voluntary patients might have a good effect.

Mr. Charles Noon, consulting surgeon to the Norfolk County Mental Hospital, said that he saw the plaintiff in May, 1937, and in January, 1941. She would not allow him to touch her. At his first visit she complained of pain more or less localized to the right hip, and he suggested an x-ray investigation as a precaution, though he did not think it likely to reveal anything. At his second visit her mental condition was worse. She now complained of intolerable pain in the palms of the hands. One slight thing which struck him was the intense dislike she conceived for a colleague's fountain pen. His view was that had she consented to undergo institutional treatment after the accident a course of three to six months would have cured her. His lordship asked what effect it would have if a bomb dropped near her bungalow, and the witness agreed that it might have a revivifying one. He added that she was quite capable of jumping; all her muscles reacted quite well. As a rule the really hysterical patient was glad to get treatment, but here there was a refusal on her own

part, and that of her husband and daughter to take the necessary measures.

Dr. Oliver G. Connell, medical superintendent, Norfolk County Mental Hospital, said that he saw this woman in June, 1939, in company with her doctor. He suggested institutional treatment, but she showed no inclination to co-operate, and her husband said she would not stand the journey. There was no reason why as a ratepayer in the county she should not enter his own hospital as a voluntary patient. The hospital had sixteen wards and she would be grouped with patients like herself. He could not conscientiously certify her. With her when it came to making up her mind it was a case of "would not" rather than "could not."

Dr. A. J. Cleveland, honorary physician, Norfolk and Norwich Hospital, said that he examined the plaintiff a year ago. He was convinced that she was not suffering from any organic lesion. As one piece of inconsistency she shrieked when he touched the palms of her hands, but on leaving he shook hands with her, pressing the palms firmly, and she showed no sign of pain. It was a severe case of hysteria; her physical condition was good, but she was sympathized with by her husband and daughter to an extent that was unreasonable and most harmful. The only treatment was to get her away from her surroundings, and he could not agree that any attempt to compel her to make the journey would have serious consequences.

Judgment for the Plaintiff

After hearing evidence as to the conditions of the accident, his lordship gave judgment for the plaintiff against the first defendant, Mr. Shead. He said that for the first two years and four months after the accident the woman was solely under the care of Dr. Owens, and during nearly all that time she was in bed, making no effort to get up, and gradually becoming worse. He was satisfied that Dr. Owens never suggested during that time any treatment other than that which he was giving—namely, soothing medicines. No suggestion was made to her that she ought to go away to a nursing home. She followed the medical advice until June, 1939, and no blame could attach to her during that period. Her pain might have been real or imaginary, but the result to her was the same. In June, 1939, Dr. Connell saw her in company with Dr. Owens, and the advice was given to her and her husband, with which Dr. Owens concurred, that she would never get better unless she went into an institution. Various institutions were mentioned—Tavistock Clinic and the Queen Square Hospital in London, and the voluntary wing of the county mental hospital. The woman refused, however, and her husband—an obstinate man, as was plain from his evidence and demeanour in the witness-box—upheld her in her refusal. He (the judge) would not use the word "malingering," but he did not believe that this woman had ceased to have a will of her own: she was capable of making up her mind negatively—that is to say, of refusing to do a thing. There was no reasonable excuse for not following the advice of the medical specialists from June, 1939, onwards, and had she done so she might have been quite well now for twelve months. In assessing damages he thought that £100 had been properly incurred in medical expenses, and £50 in domestic assistance, and that cure undertaken in an institution might cost another £100. Therefore £250 would rank as special damages, and for her pain and suffering he awarded £450, making £700 in all. He awarded it against Mr. Shead, who in his view was responsible for the accident, and ordered him to pay the plaintiff's and the second defendant's costs. He added that he hoped it would be conveyed to the woman that in his, the judge's, view she had been acting entirely wrongly since June, 1939. He was amazed that anyone should have been so foolish as to refuse to do what she had been advised by all the doctors who had seen her.

The Central Council of Recreative Physical Training has published its fifth annual report, for 1939–40, from 58, Victoria Street, London, S.W.1. In the interests of national economy a full report has not been printed and the Council contents itself with brief notes indicating the extent and diversity of the work carried out during the year ended August 31 last.

Medical Notes in Parliament

The Nation's Food

In a debate on food supplies, which was opened in the House of Lords on February 18 by Lord Bledisloe, Viscount DAWSON OF PENN spoke of the disproportion between the rations allotted to civilians and those of soldiers. There was a case for the review of Army rations. Up to now there was no evidence of malnutrition through rationing. The young were well, in good health and colour, and alive with energy. There was in certain parts of the adult population a reduction of weight which should be noted, though it was not of any moment just now. Meat was a source of first-class protein, appetizing and satisfying, but these virtues could be supplied by smaller amounts than the nation's previous habits had demanded. An immense civil population now recognized that less meat was needed. By curtailing meat Lord Woolton would do no harm, provided the nation had access to wholemeal bread, milk, cheese, potatoes, leaf vegetables, and fruit. Cheese and meat were largely interchangeable. Farmers would produce more milk if the urgency of the need was made clear to them. Importation of powdered whole milk and powdered skim milk should be undertaken to full capacity. Vegetable protein in the form of powder should also be imported. Cheese was invaluable and its present absence from the dietary was a serious loss. People should not be deprived of meat and cheese at the same time. He welcomed the standard wholemeal loaf; the grain, he said, must be milled to avoid too much roughage—this could be done by some of the newer methods. Fruit should be put into storage in the anxious year to come. He supported the plea for the production of eggs, which were specially valuable for sedentary workers and for the tired and the dyspeptics.

Lord WOOLTON said he had assured an adequate supply of white bread, but not until spring would it be fortified with those things which scientists assured him were necessary. The supply of wholemeal bread would be equal to the demand. The greatest weakness was in the animal protein foods—bacon, eggs, cheese, and meat. He was concerned at the shortage of these commodities, and especially of cheese. So long as the Mediterranean campaign went on he saw no possibility of increasing the meat ration from the present 1s. 2d. per head per week. Oils had been provided to suffice for a long time, but they would not be able to maintain the present output of food in this country for pigs and poultry, cattle and sheep. If they gave more food to the hens they would take it away from the cattle, but it would not be taken from the dairy herds, which must be maintained at almost any cost. He had told the dairy farmers what was needed in the way of milk, and had laid down generous prices for twelve months ahead. He had asked the Ministry of Agriculture for additional acreages of carrots and onions. Carrots were important, because supplies of fruit, whether home-grown or imported, would not be more than half what they had been in the past. Months ago the importation had been arranged of all the powdered milk and all the skimmed milk which could be got from overseas. Stocks were held so that in an emergency they would ensure that the children and those in hospitals were fed with milk. They would import oranges to the greatest possible extent. He had done his best to treat the poultry keepers well. He had asked that the personnel in the Fighting Forces who were engaged in sedentary occupations should be rationed on the same level as the civil population. He hoped this would soon be done.

Lord BLEDISLOE, in thanking Lord Woolton, asked that tinned vegetables should not be put on the market in the summer months.

FREE MILK AND MEALS FOR CHILDREN

Lord ASTOR inquired, in the House of Lords on the same day, whether the Government intended to subsidize meals, especially for pregnant women and for children, to improve the physique, health, and mental development of the rising generation. He said the consumption of milk under the cheap milk-in-schools scheme in October, 1938, was 2,500,000 gallons. A year later, in October, 1939, it had fallen to 1,500,000

gallons. He quoted from the circular on the provision of meals which had been issued in July, 1940, by the Board of Education in consultation with other Departments. He asked Lord Woolton to compare the present position with that in July, 1940. Lord Astor recalled that in the last war he had been chairman of a committee which indicated that if all children had the milk which the medical profession thought that they should have, there would, at some periods of the year, be no milk for the adult population. Under Lord Woolton's milk scheme, which came into operation on July 1, 2,500,000 people were benefiting a few weeks ago. That was a huge contribution to the physical and mental welfare of the child population. He urged the House to see that this advance was not given up when peace came and to do what it could to extend the principle to children over 5. He hoped Lord Woolton would give publicity to the Oslo breakfast and that in this war local authorities would recognize to a greater extent their responsibility for providing meals for children. Lord GIFFORD suggested that when commodities such as oranges were only available in small quantities infants should be given the preference. Infant welfare centres and baby clubs might be trusted with seeing that the oranges reached the infants who required them.

Lord WOOLTON said local authorities were heavily burdened, but in the subject which Lord Astor raised they were making progress. The consumption of milk in schools had indeed dropped by 1,000,000 gallons, but the consumption of milk by the population as a whole had increased by 5,000,000 gallons a month. Consumption of milk by people recognized as having prior necessity had risen to 10,000,000 gallons a month. The nation was drinking and was likely to continue to drink all the milk the agricultural industry could provide. The number of local authorities providing extra meals under the Board of Education circular of July, 1940, had increased to over 250, and the President of the Board of Education was pressing on still further. That circular referred not only to meals for necessitous children but to meals for other children. Under war conditions, when women were drawn into factories, there was more need for meals in schools. He had taken steps to ensure communal feeding centres throughout the country to deal with emergencies arising under war conditions. The Government was subsidizing foodstuffs to £82,000,000 per annum, so that food would be available to people at prices they could pay. He hoped a decision would be taken at the Ministry of Food in the course of that day about orange-juice for children.

Ill-health after Recruitment

During a debate on war pensions in the House of Commons on February 18, Sir HENRY MORRIS-JONES said that he was troubled by the number of men passed into the Army as fit by the medical boards who subsequently came under the responsibility of the Ministry of Pensions, which categorically turned them down on the grounds that the disability had not been contracted during service. It was admitted that medical boards were efficient and knew their work, and it must be accepted *ipso facto* that when a man was passed as a recruit for service he was at that time fit for service. The Ministry of Pensions had no right, if an individual contracted disability in the war, to get out of liability by saying that the disability might have been contracted if the individual had been in civilian life. He urged the Minister of Pensions to review the whole position of original acceptance by medical boards in relation to subsequent disability.

Sir WALTER WOMERSLEY said that Sir Henry Morris-Jones knew very well, as a medical man, that there were certain things that might be troublesome to an individual, but did not show themselves at the time of examination unless there was a proper examination by means of *x* rays. Having seen the attestation papers of many men he (Sir W. Womersley) had found that they had answered "No" to certain questions. The men themselves had been responsible for deceiving the examining doctor, and afterwards it had transpired that six years before a man had been under treatment for something from which he had said he had never suffered. The position he had taken up was that it had to be proved to him that a man had suffered from a constitutional disease, and that it was ascertainable from his medical record.

R.A.M.C. Help to Civil Authorities

Replying in the House of Lords on February 19 to Lord Davies, Lord CROFT said the War Office was willing to provide facilities for training the R.A.M.C. in urban areas or to assist hospital services in that district where this did not interfere with unit training in military formations or where the military commanders agreed that the units could be detached for the assistance of civil authorities. Lord Davies had asked for this assistance to urban areas which had suffered or were likely to suffer heavy casualties by enemy action. He suggested that the R.A.M.C. units might assist the first-aid and hospital services in such districts. He further asked whether opportunities would be given for units stationed in rural areas to assist the medical authorities in districts subjected to intense raids. Lord CROFT said he noted the further suggestion. It might be difficult and expensive to move units from country to town.

Calcium Content of Food

Sir ERNEST GRAHAM-LITTLE asked on February 19 for the publication of evidence in regard to the percentage of the population who under the present dietary regime exhibit calcium deficiency; and also for a statement by a recognized medical authority that the added calcium would in no circumstances injure health. Major LLOYD GEORGE said there was evidence that a considerable proportion of the population lived on diets which did not supply sufficient calcium for a desirable nutritional condition. This evidence had been provided by dietary surveys, and had been accepted by the leading nutritional experts at such representative conferences as the Technical Commission on Nutrition of the Health Organization of the League of Nations. It had been published in the Reports of the League of Nations. Lord Woolton would consider the last part of Sir Ernest's question before a decision was taken as to the quantity of calcium salts to be added to flour. The Medical Research Council had made its recommendation on the proposal to add calcium to bread before the Government announced its intention to add calcium to flour.

Mr. SEYMOUR COCKS asked Major Lloyd George on February 25 whether the *British Medical Journal* had not published evidence that the addition of calcium to bread was injurious, particularly for those suffering from kidney trouble. Major LLOYD GEORGE drew Mr. Cocks's attention to an article in the *British Medical Journal* which, he declared, said exactly the opposite.

Temporary Registration of Alien Doctors

Sir HENRY MORRIS-JONES asked on February 20, in connexion with the recent regulation permitting the temporary registration of alien doctors in this country, how many alien doctors had so far been granted this recognition; how many were in the Services; and whether the present machinery for facilitating this registration worked satisfactorily in view of the present urgent demand for trained medical personnel. Mr. ERNEST BROWN replied that eighteen alien doctors, all citizens of the U.S.A., had so far been registered under an Order of September, 1940, which applied only to such citizens and to Canadians. He was not aware that any of this group of doctors were in the fighting Services. Under a more comprehensive Order of January, 1941, the cases of some hundreds of alien doctors, who were of allied nationality or refugees from enemy countries, were being investigated as speedily as possible. None had yet been registered.

Mr. SORENSEN asked why Spanish refugee doctors were not given the same opportunity as other refugee doctors to practise temporarily in the United Kingdom. Mr. BROWN said that the object of the Order was to facilitate enrolment of suitable foreign doctors in such services as the Armed Forces of their own countries at present in the United Kingdom, and in the hospital service of this country. He was unaware that these Services would benefit by addition to the list of territories specified in the Order. He offered to consider any information from Mr. Sorensen on the number of Spanish doctors concerned.

Miss RATHBONE said the majority of Spanish doctors in this country were anti-Nazi and anti-Fascist. The services of one of the greatest experts on blood transfusion were being wasted. Mr. BROWN said he knew of some of these doctors whose services were being used in certain ways.

E.M.S. Advisory Committee

On February 20 Mr. ERNEST BROWN (Minister of Health) told Dr. Morgan that the Advisory Emergency Hospital Service Committee consisted of representatives of the Royal Colleges of Physicians, of Surgeons, and of Obstetricians and Gynaecologists, and also of Group Officers, the Central Medical War Committee, the London County Council, the staffs of London voluntary hospitals, and the medical profession in the Provinces, with the secretary and deputy secretary of the Central Medical War Committee. Its function was to advise the Minister of Health on the organization of medical personnel in the Emergency Medical Service. The committee was first appointed in October, 1939, and subsequently enlarged, by the Central Medical War Committee, and was reappointed by that committee in the present month. The members were nominated by the bodies they represented or directly appointed by the Central Medical War Committee. The committee had met on nine occasions at the offices of the Central Medical War Committee.

Doctors Transferred to Reception Areas

Dr. MORGAN asked on February 20 if the Minister of Health knew that disquiet existed by reason of many doctors under 45 years of age being appointed to reception areas at the instance of Local Medical War Committees or the Central Medical War Committee. He asked Mr. Brown to investigate the position having regard to the needs of the Armed Forces for doctors and to the fact that many doctors, either with greater domestic responsibilities or more advanced in years, were available for professional work in reception areas. Mr. BROWN answered that most of the doctors transferred from vulnerable areas to reception areas at the instance of the Central Medical War Committee or its local committees were over 45 years of age. In any case all doctors of military age came up for consideration with a view to selection for service with the Forces. The Central Medical War Committee would be glad to have particulars of doctors available for professional work in reception areas.

Allocation of Medical Man-power

Sir FRANCIS FREMANTLE inquired on February 20 what steps the Minister of Health proposed to take to decide the respective priority of needs of medical practitioners between those of the civil population, of local authorities, and of the fighting Services. Mr. E. BROWN said these questions of priority had already been considered by the Committee on the Allocation of Medical Man-power. Action was being taken on their recommendations. He was considering with the other Ministers concerned what organization should be set up to deal with similar questions that might arise in future.

On February 25 Mr. BROWN told Sir Francis that he hoped shortly to publish the conclusions of the Committee.

The Services

NAVAL COMPASSIONATE FUND

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on February 21, Surgeon Vice-Admiral Sir Percival Nicholls, K.C.B., K.H.P., in the chair, the sum of £96 10s. was distributed among the several applicants.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Surgeon Lieutenant-Commander TYRRELL GEORGE EVANS, R.N.V.R. (H.M.S. *Jervis Bay*) is now officially presumed lost. He received his medical education at St. Bartholomew's Hospital, and qualified M.R.C.S., L.R.C.P. in 1919. After filling the posts of resident anaesthetist and senior house-surgeon at St. Bartholomew's Hospital he settled in practice at Beckington, Bath. He was honorary medical officer to the Victoria Hospital, Frome, and medical officer and public vaccinator for the No. 2 District, Frome. In 1919 he was a vice-president of the Abernethian Society, and he had been a member of the British Medical Association since 1924. He leaves a widow.

ROYAL ARMY MEDICAL CORPS

Major ARTHUR JAMES WALTER ALLEN lost his life at sea in December, 1940. He was the youngest son of Mrs. M. Allen and was educated at Edinburgh University, where he graduated M.B., Ch.B. in 1924. He also took the D.R. in 1928. For some years he resided in London and was honorary radiologist to the London Jewish Hospital and later became assistant radiologist to the Western Infirmary, Glasgow. He was a member of the British Medical Association and the British Institute of Radiologists.

Medical News

Major-General H. Willans, C.B.E., D.S.O., *M.C.*, will read a paper on Army welfare before the Royal Society of Arts, John Adam Street, Adelphi, W.C., on Friday, March 7, at 1.45 p.m., with Lord Croft in the chair.

The second Pan-American Congress of Endocrinology will be held at Montevideo on March 5-8 under the presidency of Dr. Juan C. Mussio Fournier.

A private lunch was recently given by the British Medical Association in honour of Surgeon-General Thomas Parran, head of the United States Public Health Service, Dr. J. E. Gordon, who is acting as United States Liaison Officer with the Ministry of Health, and Dr. John R. Mote, who is now acting as Medical Adviser to the American Red Cross Committee in London. Sir Wilson Jameson, Chief Medical Officer to the Ministry of Health, was the other guest, and among those present were the principal Officers and officials of the Association.

On February 21 the Society of Medical Officers of Health gave a luncheon in honour of Surgeon-General Thomas Parran, head of the United States Public Health Service, Dr. F. T. H. Wood, the President, being in the chair. The Lord Mayor of London was also present, and the company assembled included medical officers of health and representatives of local authorities and of the Ministry of Health. Dr. George Buchan, who took the chair after lunch, proposed the health of Dr. Parran in a short and gracious speech, and Dr. Parran replied.

The seventeenth annual report of the Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation gives brief details of the twenty-three grants made during the year. In awarding grants the trustees favour researches that are directed towards the solution of problems in medicine and surgery or in branches of science bearing on medicine and surgery. Grants may be used for the purchase of apparatus and supplies needed for special investigations, and for the payment of unusual expenses incident to such research, including technical assistance, but not for providing apparatus or materials ordinarily a part of laboratory equipment. Stipends for the support of investigators are granted only in exceptional circumstances. The maximum size of grants is usually less than $500. Applications for grants to be held during the year 1941-2 must be in the hands of the Executive Committee before April next. Letters asking for aid must set out clearly the qualifications of the investigator, an accurate description of the research, the size of the grant requested, and the specific use of the money to be expended. Applicants should state whether or not they have approached other Foundations for financial aid. It is highly desirable to include letters of recommendation from the directors of the departments in which the work is to be done. Applications should be sent to Dr. Joseph C. Aub, Huntington Memorial Hospital, *695*, Huntington Avenue, Boston, Massachusetts, U.S.A.

Dr. J. A Fraser, deputy medical officer for the West Riding County Council, has been chosen as medical officer for the North Riding of Yorkshire, succeeding Dr. Andrew Davidson, who was recently appointed to the post of chief medical officer to the Scottish Board of Health.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended February 1, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	1941 (b)	1941 (c)	1941 (d)	1941 (e)	1940 (Corresponding Week) (a)	1940 (b)	1940 (c)	1940 (d)	1940 (e)

* Notification in certain administrative areas only.

† Includes Primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

Measles, whooping-cough, and pneumonia (primary and influenzal) are among the commoner, and cerebrospinal fever, dysentery, and poliomyelitis among the less common, infectious diseases which have increased in incidence during the week. Not only are these diseases (pneumonia excepted) more prevalent than during the corresponding week of 1940, but diphtheria and scarlet fever, whose figures declined somewhat since the previous week, are also in excess of the previous year. On the other hand, the present levels of these two diseases are well below those recorded in 1939.

Cerebrospinal Fever

Although the increase in cerebrospinal fever is appreciable it is not nearly so steep as at this period in 1940, and this affords grounds for the hope that an epidemic of the same magnitude may not occur this year. At present forty-seven administrative areas are involved, one more than in the previous week. Although the large centres of population yield the largest number of cases, the disease is fairly prevalent in rural areas, in many of which it is difficult to determine the density of the population at a given time. There were more than 5 cases during the week in the following administrative areas: Lancaster 64; London 29; West Riding of Yorkshire 20; Warwick 15; Chester 14; Glamorgan 14; Surrey 12; Devon, Durham, Gloucester, Northampton, and Southampton 9 each; Salop 8; Derby and Kent 7 each. The notifications for the week ending February 15 numbered 378.

Influenza for Week Ending February 15

In the week ending February 15, 324 deaths were ascribed to influenza in the great towns. The ratio of increase is appreciably less than between the two previous weeks. The age distribution of the deaths continues to be normal: 54% were at ages over 65 and 9% at ages under 25. In the County of London the deaths have decreased from 56 to 50. Hospital admissions in London (influenza, bronchitis, pneumonia) decreased from 811 to 526, and the daily records of the current week show no sign of increase. It is probable that the great towns will show a further increase of deaths, but the generally favourable impression conveyed by last week's figures is confirmed. All danger has not passed; there may be a continuation of the steady, slow rise of 1929, but this becomes increasingly unlikely as the season advances.

Total for 126 Great Towns, including the Outer Ring 354

Trichiniasis

Under Section 17 of the Food and Drugs Act, 1938, practitioners are obliged to notify cases of food poisoning, but as there is no definition of the term "food poisoning" it is not clear whether trichiniasis is a notifiable disease. Until this matter is settled it is hoped that practitioners will help the public health services by informing their medical officers of health of any cases or suspicious cases of trichiniasis which come to their notice.

Registrar-General's Quarterly Return

In the quarter ended June 29, 1940, there were 166,537 live births registered in England and Wales: 85,592 were males and 80,945 were females, equivalent to an annual birth rate of 16.2 per 1,000 population, compared with an average of 15.8 in the second quarter of the five preceding years. During the same period there were 118,055 deaths (60,260 males and 57,795 females), giving an annual rate of 11.8, or 0.1 in excess of the average for the preceding five years. Infant mortality was 46 per 1,000 live births, 9 below the average of the ten preceding second quarters.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m to 5 p.m.) Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*: SECRETARY, *Mediseera Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Prevention of Herpes Labialis

Dr. D. OCKMAN (Kearsley) writes: I note with interest the letter from Dr. R. F. Price (February 15, p. 262) in which he recommends that herpes labialis be "aborted" by spt. vin. rect. I wonder, however, if herpes labialis *should* be aborted. I regard this condition as the manifestation of some form of neuro-cutaneous detoxication mechanism, rather like a boil, and think that to "send it back" is opposing the natural biological mechanism. One might as well seek to abort the excretion of sweat! Is the constant plastering of such skin conditions as psoriasis, pityriasis, etc., with different ointments similarly ill advised? Insufficient attention is paid to the important excretory function of the skin. The prevention of disease must surely come from the prevention of the basic aetiological factors rather than from the attempts to obliterate the natural end-results of natural mechanisms. The opinions of some of your readers on this subject would be of great interest to me.

"C. E. G." (Furze Croft, Hove) suggests to "H. A." (February 1, p. 182) that the cause of herpes labialis should be sought in the condition of the teeth and pharynx.

Treatment of Psoriasis

Dr. P. W. A. AGNEW (Enfield) writes in reply to "S. A." (February 15, p. 262): I have had excellent results in treating a case of severe psoriasis, involving both legs, elbows, and scalp, with the use of the ultra-violet mercury vapour lamp. The treatment has extended over a period of twelve months, twice weekly, with increased time and shortened distance at each exposure. The patient has reached the nearest point to a complete recovery that I have seen with this disease.

Double Meningeal Infection

Dr. FRANK BODMAN (Bristol) writes: The case of double meningeal infection reported by Drs. K. J. Guthrie and T. Anderson (February 8, p. 193) presents some intriguing features. The chief puzzle is, Where did the Gaertner's bacillus come from? The authors claim that they have excluded the food supply, the nursing staff, other patients in the ward, and members of the child's family. This leaves only the child itself. Now this combination of infections has occurred before; as the authors point out, a relapse of meningococcal meningitis turned out to be a Salmonella meningitis in one case, and in another case a meningococcus was found in the blood stream one day and the next day a blood culture showed *Bact. suipestifer*. Perhaps I have read too many detective novels, but is not a possible solution of the mystery the criminal in disguise? Is it too much of a bacteriological heresy to suggest that the meningococcus mutated to *Bact. enteritidis*? That perhaps each type of meningococcus has its *alter ego* in the Salmonella group? How much influence has sulphonamide therapy on the metabolism of the meningococcus? Might the coccus be more likely to survive if it could mutate into bacterial form? It must be obvious that I am not a bacteriologist, but I should like to hear their opinions.

Diphtheria Incidence

Dr. W. P. MELDRUM (Bedford) writes: I think the explanation Dr. R. M. Courtauld (February 8, p. 226) requires is that epidemics of diphtheria, like some other infectious diseases, occur in cycles, and it looks as if an epidemic may be expected. Unless immunization is secured and maintained on a sufficiently large scale epidemics cannot be prevented. That is the experience gained in Canada and the United States. During epidemics there is some demand for immunization, but not sufficient; therefore the prevalence of cases is associated with immunization. On the other hand, when there is no immunization in intervals of absence of diphtheria, there are also, of course, no cases or very few. The fact to remember is that the attack rate, death rate, and fatality rate are much higher among the non-immunized than among the immunized. That is the reason for advocating immunization. If Dr. Courtauld will refer to the *Supplement* of December 21, 1940 (p. 58) he will find some very conclusive figures.

Income Tax

Appointment: Payment of Rent

"M. S." holds a salaried appointment and lives in a house at the hospital, for which he pays a rent of £100 per annum by deduction from his salary. Is he liable on the £100 which he does not receive in cash?

*** Yes. The point was decided in 1933 in the case of Osborn *v.* Swyer.

LETTERS, NOTES, ETC.

Definitely Indefinite

Dr. G. LLEWELLYN DAVIES (Hove) writes apropos of our annotation on the King's English. This no doubt is a stale complaint, but cannot you do something to cure the average doctor of whatever estate, degree, or kind from using the word "definite" or "definitely"? It is high time he was cured or he will soon be getting it mixed up with that other abomination "actually," which occurs three or four times in every sentence uttered by some of our patients. The word "definitely" or "definite" seems to act as a sort of moral prop to so many people when they are really not quite sure. That acute appendix which we suspect and which won't yield the physical signs we expect and which an extra hard "dig" with the finger *appears* to make yield up its secret; that tooth which the dentist is trying to convict or trying to absolve—yes, we are sure there was a *definite* pain or tenderness. If so and one is sure of it, why the redundancy "definite"? It is a matter for congratulation, perhaps, that no one has, so far as is known, been "contacting" any wonderful diseases lately; but that is perhaps among the things to come.

*** "Definitely" has had too long a run in slipshod speech as a variant of "yes," replacing its older cousins "absolutely" and "quite." Dr. Llewellyn Davies rightly protests against the use by medical men of "definite" when they mean "indefinite."

The Late Sir Pendrill Varrier-Jones

Mr. W. A. SIBLY, M.A., Headmaster of Wycliffe College, writes with reference to the obituary notice of Sir Pendrill Varrier-Jones (February 8, p. 220): In Sir Humphry Rolleston's account it is stated that Sir Pendrill was educated at Epsom College and at St. John's College, Cambridge. As a matter of fact he went to Epsom College as a very small boy and came to Wycliffe College when he was 14 years of age, and remained at Wycliffe until he was 19. It was from Wycliffe that he went to St. John's College, Cambridge. So much did he appreciate his Wycliffe connexion that he founded a scholarship, called the Margaret Varrier Scholarship, from Wycliffe to Cambridge some years ago, and at the time of his death he was the president of the school.

Etchings of Westminster Hospital

Mr. IAIN M. MACLEAN, editor of *The Broad Way*, writes from Westminster Hospital, London, S.W.1: Through the courtesy of your columns I should like to draw the attention of all those who qualified from Westminster Hospital to the following. Many of you, although not contributors to *The Broad Way*, may wish to know that the following series of etchings of the hospital will be published (as a free supplement) in the next four issues of our gazette: the hospital (1) in 1734; (2) in 1834; (3) in 1924; (4) in 1939. The artist is one of our present students, and the etchings are suitable for mounting and framing. The first issue of *The Broad Way* containing one of these etchings will be published soon, and if any old Westminster man would like to make certain of getting all the issues will he please communicate with me.

Tubunic Ampoule Syringes

Discussing the administration of morphine to air-raid casualties, correspondents in the *Journal* have referred to the success they have had with the tubunic ampoule syringe. Roche Products Limited write to say that they are issuing omnopon, 1/2 grain, in this new packing, which is of British design and manufacture.

LONDON SATURDAY MARCH 8 1941

PRIMARY THROMBOSIS OF CEREBRAL VEINS (FOLLOWING CHILDBIRTH)

BY

J. PURDON MARTIN, M.A., M.D., F.R.C.P.

Physician to Out-patients, National Hospital, Queen Square; Neurologist, British Postgraduate Medical School

AND

H. L. SHEEHAN, M.D., M.Sc.

Pathologist and Director of the Research Department, Glasgow Royal Maternity Hospital

Using Gowers's (1892–3) classification, thrombosis of a cerebral vein is "primary" if it is due to "the state of the blood and circulation generally" and is not consequent upon disease adjacent to the brain or venous sinuses—e.g., in the ears. Evidence is gradually accumulating that primary thrombosis of a vein (or veins) on the surface of the brain is not a very uncommon condition. Few uncomplicated cases have, however, been described in which its occurrence has been established by post-mortem examination or by exploratory operation, and its clinical and pathological features are not at all widely known.

We are able to present three cases which came to necropsy and one in which the thrombosed vein was seen at operation, and to refer to other cases in which the clinical features were so similar to those of the verified cases that there can be little doubt that they had the same pathology. Since we are concerned only with the effects of thrombosis of the veins we shall exclude from consideration cases in which, according to our judgment, the venous obstruction was due to occlusion of a cranial sinus, even if the thrombosis of the sinus was "primary."

Primary thrombosis of cerebral veins happens sometimes in childhood and less often in old age: during the active period of life its most common association seems to be with childbirth, but it occurs also with general and local infective conditions, and sometimes without any such recognizable causal factor. At a recent discussion the two of us referred, independently of each other, to cases arising during the puerperium (Martin, 1939; Sheehan, 1939), and this paper will be made more compact if we limit ourselves here, so far as is possible, to cases arising under such circumstances. The puerperal cases will serve to illustrate the symptoms and pathology of primary cerebral venous thrombosis in general; at the same time they have an importance of their own in that they demonstrate the nature of certain alarming cases usually regarded as due to "late eclampsia" or to cerebral embolism.

Anatomy

According to O'Connell (1934) eight veins, on the average, pass up from the superficial middle cerebral vein (which lies in the Sylvian fissure), and make anastomoses over the frontal and parietal lobes with the superior longitudinal sinus. Veins arising on the surface of the brain join on to them. The positions of four of these veins are relatively constant, one lying in each of the precentral, central (Rolandic), and post-central sulci, and one in the parieto-occipital sulcus. The more posterior members of the group bend forward as they approach the upper border of the hemisphere and enter the sinus obliquely, in a direction which is thus partly contrary to that of the blood flow in it. Each of the larger superior cortical veins as it passes from the lateral (superior) surface of the brain receives a large tributary from the medial surface of the hemisphere.

Case I

Convulsions ten days after delivery; death one and a half days later. Necropsy: thrombosed veins over right prefrontal area.

A 5-para aged 41 admitted to hospital December 9, 1935, had a normal pregnancy and delivery. The puerperium was uneventful for the first nine days with normal lochia and no pyrexia; nine days after delivery she complained of slight headache. The next day she suddenly became unconscious and had a fit followed by a series of fourteen other fits in the course of twenty-four hours. The temperature rose rapidly to 107° F. The cerebrospinal fluid was clear and under normal pressure; the urine contained albumin and blood; the blood pressure was 145/90 mm. Hg. She remained comatose but without any evidence of hemiplegia, and died thirty hours after the onset of the fits.

Necropsy revealed early bronchopneumonia, healed tuberculosis of the mesenteric glands, some old scars of healed pyelonephritis in both kidneys, and old pleural adhesions on the left side. The uterus was healthy, with normal involution. The other organs, apart from the brain, were also healthy.

The brain showed an area of early cortical softening on the outer aspect of the right prefrontal region about 5 cm. in diameter. In the pia arachnoid over this softening there were two or three thrombosed veins and some small areas of haemorrhage. The superior longitudinal sinus was not examined.

In this case the vessels thrombosed were some of the variable veins in the right prefrontal region, and the onset of convulsions probably coincided with the time of their obstruction. Although a softening was produced, no paralysis was observed, and this was evidently because the lesion was well in advance of the motor area of the cerebral cortex.

Case II

Fits from fourth to eighth day after delivery. Right hemiplegia. Death fifteen days after first fits. Necropsy: thrombosed veins over precentral gyrus; "rat-tail" thrombus in superior longitudinal sinus.

A 10-para aged 39 was admitted on September 11, 1937. She had a normal pregnancy and labour. For the first three days of the puerperium she was apparently well, with normal

temperature and pulse and normal lochia. On the fourth day after delivery she had a fit and developed a right-sided hemiplegia. During this day she had several further fits, during which the right arm was rotated outwards, but the right leg remained still; there was no loss of consciousness. On the seventh day after delivery four similar fits occurred, and on the eighth day two fits.

The blood pressure was 155/85 to 165/95 mm. Hg on the fourth day post partum, but thence varied between 135/80 and 120/75. The temperature rose on the seventh and eighth days to 100° F., and afterwards there were occasional temperatures of 99° F. to 99.5° F. The pulse rate was 70 to 80 per minute for the first week of the puerperium, and afterwards ran at 100 to 110. The urine contained a slight amount of albumin and lactose; the blood urea was 32 mg. per 100 c.cm. seven days after delivery. The lochia were always normal.

The hemiplegia remained unaltered, but the patient seemed to be improving until nineteen days post partum, when she developed cyanosis and a sense of oppression in the chest. This was partly relieved by oxygen; but after about twelve hours she became suddenly more distressed, and died rapidly. At the necropsy the immediate cause of death was found to be a true thrombosis of both pulmonary arteries. The thrombus was firm and grey and occupied most of the branches of these arteries; it appeared to be a few days old. There was no evidence of pulmonary embolism or of lung infarcts; the lungs were dry and rather tough. The right ureter showed a pregnancy dilatation of considerable degree but was not inflamed. The right ovarian veins in the pelvis were thrombosed. The uterus was healthy, with normal involution. The other organs, apart from the brain, were normal.

The brain showed an area of reddish softening of the cortex of the upper part of the left hemisphere, centred near the upper end of the precentral gyrus. This was about 5 cm. in diameter at the surface and about 2 cm. deep; it was surrounded by a zone of yellow staining and softening about 1 cm. in thickness. In the pia arachnoid over the softening there were three large veins distended with red thrombus. The superior longitudinal sinus contained a pale thrombus along its whole length back to the torcular Herophili; this was thicker and whiter, and was adherent near the junction of the thrombosed meningeal veins, but did not occlude the lumen of the sinus.

Microscopically the cerebral softening was typical of advanced necrosis, and the surrounding yellow zone was packed with compound granular corpuscles full of lipoid.

In this instance the onset of fits and of right hemiplegia is presumably to be attributed to thrombosis in the veins over the left cerebral hemisphere and the resulting softening. It is not possible to say when the clot in the superior longitudinal sinus developed, and as it did not obstruct the lumen it is doubtful whether it gave rise to any symptoms.

Case III

Weakness of left arm fourteen days after delivery, followed by repeated convulsions. At a later stage, high intracranial pressure. Thrombosed Rolandic vein seen at operation. Eventual excellent recovery.

This woman, aged 32, was admitted to hospital on March 18, 1934, under the care of one of us. Her first baby was born on March 3, and the puerperium was normal except for a rise of temperature to 99° F. on the third day. On March 17 she complained of a slight headache and had some temporary weakness of the left arm. Next morning on waking she had a headache, her left hand was paralysed, and her tongue felt too big for her mouth. (She may have bitten it during a fit in her sleep.) Soon after waking she had a fit, which began with jerking of the left arm and left side of the face. Four similar fits occurred during the morning, and she was then admitted to hospital, and during the next twenty-four hours had seventeen fits. She had complete paralysis of the left hand and gross loss of sense of position in it. The left side of the face was paralysed; there was only slight weakness of the left leg, but the plantar reflex was extensor.

The central nervous system was otherwise normal, and the other systems showed no abnormalities. The cerebrospinal fluid pressure was normal: the fluid contained 1,700 blood cells per c.mm. but was not otherwise abnormal. The fits practically ceased on the second day and the patient made good progress until the sixteenth day. She then had a fit, and another on each of the two succeeding days; these were followed by a rise of intracranial pressure to 240 mm. of fluid, with morning headaches and papilloedema, signs which eventually led to an exploratory operation. At the operation, performed by Mr. Geoffrey Jefferson on the sixty-ninth day of the patient's illness, the dura was found slightly adherent over the fissure of Rolando, and instead of the normal appearance of the vein in the fissure there was a white opaque streak. The motor cortex appeared softened, but stimulation of it produced responses in the contralateral limbs. The patient made further improvement after the operation, and left hospital a month later without disability.

This case shows two phases. There can be little doubt that the alarming symptoms which occurred at the beginning of the illness were due to thrombosis of the right Rolandic vein, which ten weeks afterwards was seen as an opaque streak in the arachnoid. The cerebrospinal fluid contained numerous blood cells, but the pressure of the fluid was normal. The second phase began on the sixteenth day, when the patient had a recurrence of fits, and thereafter signs of raised intracranial pressure appeared. This rise of pressure may be taken as an indication that the absorption of cerebrospinal fluid by way of the Pacchionian bodies and the superior longitudinal sinus had been obstructed, and thus as evidence of occlusion of the sinus, or at any rate of its "upper story," by clot. Hydrocephalus in connexion with thrombosis of the superior longitudinal sinus has been described in cases of various kinds by Bailey and Hass (1937), Frenckner (1934), Symonds (1937), Ellis (1937), and others.

Case IV

Symptoms of thrombosis of cerebral veins seven days and forty-two days after delivery. Death three years later. Necropsy.

About a week after her sixth confinement, when she was 27 years old, this patient, a 7-para aged 30, had a single convulsion. There are, unfortunately, no further details available about her condition at that time and during the next few days. Three weeks later she had a slight thrombosis of the superficial veins of the right leg; this cleared up satisfactorily. Two weeks afterwards (i.e., six weeks post partum) she suddenly developed paresis of the right arm and leg. The right plantar reflex was extensor; the other reflexes and the eyes were normal. The blood pressure was 110/70. Blood examination showed a marked anaemia: R.B.C., 2,540,000; haemoglobin, 20%; W.B.C., 5,000; urea, 49 mg. per 100 c.cm. Wassermann negative. No abnormality was found in any other system. The hemiplegia gradually disappeared during the next month, though subsequently she had occasional attacks of fainting with unconsciousness, but without any convulsions.

This patient died three years later (April 26, 1940) as a result of ante-partum haemorrhage and uterine sepsis in her seventh pregnancy, and a post-mortem examination was made. The brain showed three depressed scars in the cortex, one over the upper part of the left parietal region and one on the upper aspect of each frontal lobe. These scars were all about 2 to 3 cm. in diameter and 1 cm. deep. The overlying pia arachnoid was brown, thick, and moderately adherent. No remaining thrombosis of cerebral veins or sinuses could be distinguished. On section the depressed areas of the brain surface showed only a thin layer of cortex, which was dark in colour; beneath this the white matter was soft and shrunken. Microscopically these portions showed, almost exclusively, loosely formed glia with few remaining nervous elements.

The history and the pathological findings in this case indicate that three separate cortical veins had thrombosed after the sixth delivery. The convulsion seven days after

delivery was presumably related to one of the frontal lesions; the hemiplegia which occurred later was due to thrombosis of a vein over the left parietal cortex. It is of interest that the latter thrombosis was not accompanied by convulsions, and this brings out the important point that convulsions are not an essential element of the symptomatology. In our experience they are usual, but have not been a prominent feature of all the verified cases of primary cerebral venous thrombosis hitherto published. They occurred in Davis's (1933) case and in Money's (1890), but Dowman's (1926) patient merely had slight attacks of a twitching sensation in the right upper eyelid: fits are not mentioned by Irish (1938) in regard to two cases of primary thrombosis in his series (Nos. 1 to 4), but one of the patients had cramp. A presumptive case without fits has recently been described by Symonds (1940).

Another point of interest in this case is the virtual disappearance of the thrombosed veins three years after the event. In the preceding case the affected vein was seen evidently in process of being absorbed; while Bailey and Hass (1937) have described, in the case of an infant, both the formation of new vessels and canalized thrombi in the superior cerebral veins two and a half months after the presumed time of thrombosis.

Previously Reported Cases.—The puerperal cases reported up to 1904 were included in v. Hösslin's collection (1904, 1905). Of other, more recent, cases Dowman's (1926) was confirmed at operation, and ended in complete recovery. Davis's (1933) case was confirmed, both at operation and post mortem. Waggoner's (1928) was complicated by the presence of an angioma. Two uncomplicated cases of primary venous thrombosis occurred among a group of pathological cases described by Irish (1938). None of these cases was puerperal. Cases in children are in a somewhat different category, and we have not taken account of them all. Money's (1890) case was referred to by Gowers (1892–3), and in the more recent literature there are two post-mortem cases in children with heart disease described by Lhermitte and his co-workers (1936).

For the purpose of establishing the pathological nature of these cases we have necessarily made use of those in which the diagnosis was verified. But we do not wish to give the impression that the condition is always a fatal one. On the contrary, the majority of patients make good recovery. We have seen three other puerperal cases, and a number not associated with childbirth, which in their initial clinical features were closely similar to those already described, but ended happily. The following account, though it describes the most severe of the three puerperal cases, may be taken as typical of all of them.

Case V

Cramp and fits ten days after delivery: incomplete left hemiplegia. Good recovery in three weeks

A primipara aged 25 was confined on June 30, 1938. Labour was normal and the puerperium was uneventful until July 10, when she complained of "cramp" in her left hand and a feeling of faintness. During that evening she had three epileptiform fits, with the twitching more pronounced on the left side, and next morning she found that her left arm was weak. On admission to hospital at 12.50 p.m. that day the patient was able to speak but was stuporous: she had obvious weakness of the left side of her face, and did not move her left arm. There was no stiffness of the neck, and nothing abnormal was found on examination of the heart, lungs, and abdomen, or in the ears; her urine, taken by catheter, had a high specific gravity (1036) but was otherwise normal. Her temperature on admission was 100° F. and her pulse rate 108. The temperature was normal by the following morning and remained so until the next day, when three more brief fits occurred involving loss of consciousness; her temperature rose to 100.2° F., but had returned to normal by 10 o'clock next morning. Her blood pressure was 120/80 mm. Hg; the blood Wassermann was negative.

When examined on the sixth day of her illness she was listless and moderately drowsy. She had incomplete left hemiplegia, the face and hand being most affected and the leg much less, but the left plantar reflex was extensor. There was a loss of sense of position in the fingers of the left hand. The cerebrospinal fluid pressure was not measured, but there was no suggestion, either then or later, that it was increased. The patient's condition steadily improved. In a few days she was quite alert mentally, and within a fortnight of her admission her left hand had recovered a great deal of its power and postural sensibility. She was discharged from the hospital on August 9 after a stay of four weeks and a day, and was then using her left hand normally. There was still very slight weakness in the left side of her face, and the tendon jerks on the left side of her body were distinctly greater than those on the right; the left plantar reflex was indefinite.

When seen again three months later she declared herself quite well except for slight attacks of numbness in the left hand.

There can be little doubt that in this case, as in Case III, the right Rolandic vein was involved. It was probably not thrombosed up to its entry into the superior longitudinal sinus, because the absence of paralysis in the left leg indicates that the tributary from the medial surface of the hemisphere was not obstructed: this tributary enters the main vein as it leaves the surface of the brain to cross over in the arachnoid to the sinus. There were no complications, and recovery was made much quicker than in Case III.

When veins over the more posterior parts of the cerebral hemisphere become thrombosed visual disturbances are likely to ensue. In the following instance, which was not associated with childbirth, it is likely that part of the vein which runs up to the parieto-occipital fissure or one of its tributaries was occluded. Word blindness, attributable to disturbance of function in the adjacent angular gyrus, was among the symptoms.

Case VI

Typhoid fever. Epileptiform attacks followed by word blindness and impairment of postural sense in right hand. Good recovery.

A girl aged 18, recovering from typhoid fever, had seven epileptiform attacks one morning and was afterwards stuporous. When seen four days later she showed no loss of power, but recognized objects in the right hand with less confidence than in the left. She was quite unable to read, although her acuity of vision and visual fields seemed normal. Her tendon jerks were brisk and her plantar reflexes flexor. Her condition gradually improved, and in about six weeks she seemed to have completely recovered.

Comments

These cases show the clinical picture of primary cerebral venous thrombosis and its variation according to the position of the vessels involved. Regarding the subject in its larger aspect the main divisions that call for discussion are: (1) the thrombosis; (2) its effect on the brain; and (3) the clinical features to which these jointly give rise.

The Thrombosis

Aetiology.—The special anatomical factors which favour thrombosis in the veins on the surface of the brain were stressed by Gowers (1892–3). We are inclined to attach less importance than he did to their vertical direction, but the slowness of the blood-flow in them and the fact that the blood leaving them enters the longitudinal sinus in a direction contrary to the current are

probably significant. The more general factors which favour the thrombosis are not well known. In an important group of cases primary cerebral venous thrombosis occurs in the puerperium, which is a time at which thrombosis is particularly apt to arise elsewhere in the body. Nearly all the other cases are associated with conditions in which diarrhoea and vomiting is an added element—typhoid fever, ulcerative colitis, gastro-enteritis—but also (as we have seen in another instance) such a mild infection as "gastric influenza" in a vigorous young subject. In the puerperal cases there is certainly no relation to sepsis which can be recognized clinically or at necropsy. Nevertheless, even though the puerperium has apparently been normal up till the onset of a convulsion, the possibility of a symptomless infection cannot be excluded: positive blood cultures are found in a high percentage of normal women for an hour or two after ordinary delivery. Cerebral venous thrombosis is certainly not a result of difficulty at the delivery: in nearly all the cases this has been quite normal.

Formation of the Thrombus

The exact mechanism by which this thrombosis occurs in cerebral veins has not been fully worked out. An analogy may, however, be drawn with the thrombosis sometimes found in femoral or ovarian veins after delivery, in which the probable sequence is as follows: (*a*) A small pale thrombus forms at the junction of a tributary vein with a large vessel. It is attached along a very narrow longitudinal line at the cardiac side of the junction. (*b*) It enlarges until it rather suddenly obstructs the mouth of the tributary vein, which immediately becomes distended by a firm red thrombus made up mainly of packed red corpuscles. (*c*) The primary thrombus also enlarges into the lumen of the main vein, where it forms a grey "slug" on the wall; later this may gradually extend in either direction along the main vein as a long grey thrombus, sometimes with branches down other tributary veins. This secondary thrombus is formed in blood which is still flowing (though probably somewhat sluggishly), and it usually lies free in the lumen.

The conditions which have been found in the cerebral veins correspond with this interpretation. The distension by red thrombus of one or two of the veins in the arachnoid over the hemisphere is the most striking appearance on opening the skull in these cases. The manner of its development may be considered according to the three stages mentioned.

(*a*) In Case II the site of the primary mural thrombus was identified by the grey slug at the junction of the thrombosed arachnoid vein with the superior longitudinal sinus. But it is not clear whether this is the usual site; it seems probable that in other cases the primary thrombosis occurs at a junction of two arachnoid veins some distance from the sinus. (Since our necropsy technique was modified to study this point we have not had a case of this kind.) The sparing of the leg in Cases III and V must be taken as evidence that the tributary vein from the medial surface of the hemisphere was not obstructed, which suggests that the Rolandic vein was not thrombosed up to its point of entry into the sinus. In some cases in the literature (especially that of Davis, 1933) it is expressly stated that the thrombosis of the arachnoid vein did not extend up to the junction with the superior longitudinal sinus, and in these it may be accepted that the primary thrombosis was at the junction of one arachnoid vein with another. On the other hand, it seems that the point of entry of a vein into the sinus is a likely site for the initial thrombosis owing to the partly opposed directions of flow of the joining blood streams, with the consequent formation of an eddy. In a fatal puerperal case described by Symonds (1937) multiple mural thrombi were seen post mortem on the side of the sinus, and Gowers (1892–3) states that a layer of clot is sometimes found on the wall of the sinus.

(*b*) The red thrombus in the arachnoid vein presumably forms suddenly when the vein is blocked. After a few weeks it becomes decolorized and shrinks as in Case III; after a few years it is no longer recognizable, as in Case IV.

(*c*) When the primary thrombus is on the wall of the superior longitudinal sinus, or if it eventually reaches up to it, the secondary grey thrombus may extend, as in Case II, in the blood flowing along the sinus. It is easy to believe that in some cases this may become so large as to produce mechanical obstruction of the sinus, or that it may become adherent in places to the wall of the sinus. Such occurrences may produce further effects—interference with the absorption of cerebrospinal fluid into the superior longitudinal sinus (as indicated by the clinical signs in Case III) or the obstruction of the mouth of other meningeal veins and consequent red thrombosis of these veins. The latter process may have been responsible in our Case IV for the late thrombosis which caused necrosis of the parietal cortex. A possibility which must not be neglected is that certain of the results apparently due to the secondary thrombus may actually be caused by more than one primary thrombus. This is suggested by the multiple mural thrombi in the sinus recorded by Symonds (1937). On the other hand, in our Cases III and IV the time of development of the later symptoms is in accordance with the explanation that these were secondary.

The Cerebral Lesion

Thrombosis of a vein in the retina provides a dramatic illustration of the effects of venous occlusion in a delicate tissue: numerous small haemorrhages are seen where venules draining into the obstructed vein have ruptured. Something similar evidently occurs in the meninges and in the brain. Frequently one of the first effects is the development of small subarachnoid haemorrhages about the size of a postage stamp or smaller (Case I). This has also been described by Davis (1933), Lhermitte, Lereboullet, and Kaplan (1936), and Irish (1938). The amount of blood may be sufficient, as in Case III, to cause easily recognizable blood in the cerebrospinal fluid obtained at lumbar puncture. Haemorrhages of various sizes may also occur within the brain substance as in Symonds's (1937) case, in two cases in children described by Lhermitte and his co-workers (Armand-Delille and others, 1936; Lhermitte and others, 1936), and in Davis's case.

Necrosis of cerebral tissue without haemorrhage seems, however, to be a more common effect. Our fatal cases show that there is a rapid softening of the area of the hemisphere drained by the affected vein. It is an ordinary reddish necrosis affecting cortex and underlying white matter, and in extent varies from 2 to 5 cm. in diameter. In the fatal cases there is no doubt about the complete nature of the necrosis, either to the naked eye or microscopically, but in non-fatal cases it may be less intense, and in Case III the altered cortex was still capable of response to electrical stimulation. After some days it is surrounded by a broad yellow zone of compound granular corpuscles loaded with lipoids. In the healed stage it becomes a shrunken depressed area 1 to 2 cm. in diameter, with the pia arachnoid somewhat thickened and the arachnoid lightly adherent over it; the general build of the atrophied convolutions can be made out, but the microscopical structure consists of little else but glial fibres.

In the operated cases reported in the literature (Dowman, 1926; Davis, 1933) the condition found was non-haemorrhagic, as in Case III.

Clinical Features

In puerperal cases the onset of the acute illness is most commonly between four and twenty days post partum; usually the delivery has been normal and the puerperium quite uneventful up to that time. The first symptom in most cases is the occurrence of one or more fits. If,

however, a detailed history can be obtained it is often found that the first fit was preceded by some symptoms such as headache or intermittent cramp or weakness of a limb. The fits probably coincide with the sudden obstruction of the meningeal vein and the formation of red thrombus in it. They are to be ascribed to cellular disturbances in the area of cortex in which the venous drainage has been abruptly arrested. The exact site of the cortical lesion is not of great moment: fits seem to occur almost as frequently when non-motor cortex is involved as when motor cortex is concerned. In many cases the fits continue over several hours or days; they are most evident in, and sometimes limited to, the part or side first affected. Recurrence of fits after an interval may indicate that the thrombosis is spreading. The incidence of coma in relation to the fits is very variable. Some patients appear to be conscious immediately after the fit. Prolonged coma is of bad prognostic significance.

After the fits the condition depends on the site of the thrombosis. If the lesion is in the frontal or occipital area no paralysis may be observed. But if the motor cortex is involved, as is commonly the case, there is usually complete paralysis of one limb and weakness of the rest of that side of the body. In our experience the arm is generally the part most severely affected.

The cerebrospinal fluid is as a rule normal unless the subarachnoid haemorrhages have been extensive, when a little blood may be present. There may be slight pyrexia, some albuminuria, and mild hypertension, but these conditions usually clear up in the course of a few days. A transient rise of blood uric acid due to the convulsions is also to be expected (Crawford).

When the convulsive stage is over the patient is in no direct danger from the cerebral lesion, though she is still exposed to the risks of spreading thrombosis in the veins or in the superior longitudinal sinus, or of thrombosis of vessels in other parts of the body. In many cases the paralysis has almost completely gone in the course of a few weeks. Evidently, with the re-establishment of venous drainage the parts of the cortex forming the margin of the lesion are capable of recovery, and the residual lesion, although anatomically considerable, as is shown by our Case IV, is not sufficient to cause paralysis. Two factors possibly help to explain why recovery is much better in these cases than in arterial thrombosis or haemorrhage. The first is that the lesion is on the surface of the brain, where a larger lesion is required to produce the same degree of paralysis than if the lesion is, say, in the internal capsule. Secondly, in cases in which haemorrhage occurs the blood is effused under a lower pressure than in cases of arterial bleeding and so causes less disruption of fibres, and greater recovery is consequently possible when the blood is absorbed.

Recovery is not so complete in all instances, and in more than one presumptive case we have seen residual symptoms. There can be little doubt that in all cases gross anatomical lesions of the cortex are left, and the degree of clinical recovery that is usual provides an illustration that a considerable cortical defect can exist with few or no symptoms.

Diagnosis

The signs and symptoms of cerebral venous thrombosis are not pathognomonic, but the syndrome, taken in conjunction with the conditions in which it arises, is fairly clear. The differential diagnosis of the cases which occur in the puerperium ranges over all the conditions which may cause fits or paralysis at that time, whether peculiar to obstetric cases or not, and it is manifestly impossible to discuss it fully here. Many of these cases have in the past been regarded as "late eclampsia"; the existence of this disease is doubtful, and most of the signs and symptoms on which it is diagnosed are seen in cerebral venous thrombosis, as noted above. Other cases have been ascribed to cerebral embolism from thrombi in the pelvic or femoral veins: this presupposes a patent foramen ovale—an assumption that is rarely justified by the anatomical findings. A further cerebral condition involving hemiplegia associated with blindness of one eye which may occur several days after delivery and thus give rise to difficulties of diagnosis has been fully discussed by Wright Thomson (1940).

Treatment

Much of the treatment is on obvious lines. Luminal, 2 or 3 grains by mouth or intravenously, will usually control the convulsions, and afterwards smaller doses should be administered for a week or two, and massage or passive movements should be given to paralysed limbs. Unless other complications supervene the patient will in most cases have made a good recovery in a few weeks. Since there is often evidence of extension of the thrombosis after the first symptoms the administration of heparin should be considered as soon as the condition is recognized. We have, however, had no opportunity of trying it. In the puerperal cases the danger of uterine haemorrhage would seem to be the principal risk entailed in its use, and the possible danger, in all cases, of the liberation of emboli will have to be taken into account.

Summary

The clinical features and the pathology of primary cerebral venous thrombosis are illustrated by a group of six cases.

In two of these cases the diagnosis was established post mortem and in one case at an exploratory operation. A fourth case came to necropsy three years after the onset, and in the other two cases the diagnosis is presumed because of similarity of symptoms and circumstances with those in the verified cases.

In five of these cases the symptoms occurred after childbirth. Such cases have usually been regarded as instances of "late eclampsia" or cerebral embolism.

Primary cerebral venous thrombosis occurs in the puerperium and in conditions of general and local infection—especially in those associated with vomiting or diarrhoea.

As a result of the venous blockage, softening, with in some cases haemorrhage, occurs in the brain and a permanent residual scar is left on the cerebral cortex.

The outstanding clinical features are fits and paralysis. The fits may be local or general, and in occasional cases may be absent. Premonitory symptoms occur in many cases. A small amount of blood may be found in the cerebrospinal fluid. The relation of these symptoms to the pathological features is briefly discussed.

It is suggested that when the condition is recognized heparin might be tried with a view to preventing spread of the thrombosis.

We are indebted to Mr. O. R. M. Kelly of Whipps Cross Hospital and to Dr. W. A. Steel of Hillingdon County Hospital for permission to make use of Cases V and VI respectively.

THE RECRUIT'S HEART

BY

E. NOBLE CHAMBERLAIN, M.D., M.Sc., F.R.C.P.
Honorary Physician to the Heart Clinic, the Royal Infirmary, Liverpool

The following analysis is presented to call attention to the types of problem met with in the grading of abnormal conditions of the cardiovascular system. The series includes 130 cases referred from recruitment medical boards. Most of them were sent on account of murmurs, a few on account of tachycardia or abnormal rhythms, and a few because of a rheumatic history associated with minor abnormalities of the heart sounds or rhythm. The instructions for grading these cases are laid down, and are in the possession of the chairmen of the medical boards. Reference to some of these instructions was made in the *Journal* of August 10, 1940 (p. 201), under the title of "Effort Syndrome," giving the results of Lord Horder's Committee's recommendations to the Minister of Labour on the examination of the cardiovascular system. These instructions are a valuable guide to the medical boards, and the following series of cases has been considered with special reference to the instructions to see how far the individual case is cared for by the details given.

It is presumed that most of the cases included here presented some doubtful point in diagnosis or assessment of the grading. The frank cases of valvular disease, hypertension, and grosser cardiac irregularities would no doubt have been diagnosed and classified without any difficulty. It is therefore of some interest to observe which of the series required special methods of examination such as radiograph or electrocardiogram before a satisfactory opinion could be given. The cases are perhaps best dealt with under the headings of the diagnosis made, which included: (1) murmurs without organic significance; (2) murmurs indicative of organic disease; (3) hypertension; (4) effort syndrome; (5) abnormal rhythms; and (6) cardiovascular degeneration.

Murmurs without Organic Significance

Lord Horder's Committee makes the following recommendations on systolic murmurs:

> "A systolic murmur heard at the apex cannot be accepted in itself as evidence of structural disease of the heart, but when it is present a high grade of exercise tolerance should be required and care should be taken to exclude enlargement and mitral or aortic disease. A history of acute rheumatism or of dyspnoea on exertion, or the characters of the murmur, may help in the diagnosis. If the systolic bruit is slight and is the only abnormal sign the man may be accepted as Grade I provided he has good exercise tolerance."

In the present series a systolic murmur without other grossly abnormal signs was found in 36 cases, and these were recommended for full military service. It is of interest to note that in 28 cases the murmur was apical, in 3 basal only, and in 5 apical and basal. Of the apical murmurs 9 were audible in recumbency only. The remainder were heard to a less degree in the erect posture, but in only 1 case was the murmur audible more clearly in the erect position. Some of the murmurs were soft and some roughish in character, but none was really harsh. At the apex the murmur was noted to be soft in 26 cases out of 32. Slight conduction of the apical murmur towards the axilla occurred in 5, but, as it is generally conceded that conduction is merely an expression of the intensity of the murmur, this was not held to be evidence of organic changes in the mitral valve. *X*-ray screening showed the heart in all cases to be within the physiological limits of shape and size.

It is of course true that little is known of the origin of systolic murmurs, which are usually regarded as harmless, but general experience since the last war has shown that murmurs such as occurred in the present group may persist indefinitely without any further signs of valvular heart disease appearing and without any functional incapacity of the organ.

In connexion with these systolic murmurs it should be added that other slight deviations from the normal were occasionally present and were not considered sufficient to relegate the patient to a lower grade. They included slight forcibility or diffuseness of the cardiac apex beat, which usually settled down towards the end of the examination and was clearly emotional in origin; occasional reduplication of either the mitral first or the pulmonary second sound; extrasystoles; and occasional slight radiological convexity of the pulmonary arc (which was regarded as within physiological bounds) and minor deviations in the electrical axis. The systolic murmurs considered to indicate organic disease are dealt with later.

Murmurs Indicative of Organic Disease

1. Mitral Disease.—Twenty-three cases in all fell into this group. In 9 of these it was possible to diagnose mitral stenosis on clinical grounds by the discovery of the usual diastolic or presystolic murmur. It is only necessary to add that the familiar methods of eliciting these murmurs in doubtful cases once again proved their usefulness—namely, that the murmur was often audible only in recumbency, especially with the patient lying partially on the left side, and in all cases the murmur was much more evident after exercise. Many of these cases presented no cardiac symptoms, and the patient was capable of good physical effort, in two instances of work as dock labourers. The remaining cases in which the murmur was systolic present the greatest difficulty, and it is sometimes impossible to give a dogmatic opinion as to the suitability of the recruit for military service. None the less, in some the murmur, though systolic in tone, was combined with adverse features sufficient to suggest that the individual would not be fit for full military service. The following case illustrates this point:

> "Rheumatism in 1927. Cardiac impulse forcible but not diffuse. Apical systolic murmur persistent and conducted slightly. Slight impurity of the aortic second sound but no definite aortic diastolic murmur. Radiograph: Moderate generalized enlargement with rounding of the left ventricle, some dilatation of the aorta, and definite right auricular enlargement."

Another case, on the other hand, left some doubt as to whether the mitral valve was actually affected, but the combination of a conducted systolic murmur with forcibility of the cardiac apex beat and a fairly recent history of serious internal haemorrhage made it desirable to put the patient in a low grade more on general principles than from conviction of the organic nature of the valvular murmur.

In all, 15 patients in whom the presenting abnormality was a systolic murmur were recommended for lower grading. In a few of these it was thought that Grade II might be suitable, as, for example, in a man with a history of repeated rheumatism and a systolic murmur who had a good exercise-tolerance test and a normal radiograph and electrocardiogram. Similarly, in 2 cases with systolic murmur the radiograph showed slight prominence of the pulmonary arc. Such cases left a little doubt as to whether they were really suitable for Grade I, although it was thought probable that there was no organic heart

disease. Similar doubt existed with regard to another 2 cases in which the systolic murmur was accompanied by rather more arteriosclerosis than one would have expected in a young man. Still lower grading was recommended when the systolic murmur was associated with well-defined cardiac enlargement, especially right auricular enlargement or pronounced prominence of the pulmonary arc as detected radiologically. In some cases the systolic murmur was accompanied by a history of rheumatism and other suspicious signs—e.g., systolic shock, a doubtful diastolic murmur, or pronounced right ventricular preponderance. Several cases were recommended for low grading on account of systolic murmurs and an associated condition such as bronchitis, emphysema, or doubtful hyperthyroidism. In only 1 case was the electrocardiogram the deciding factor. In this the systolic murmur without other physical signs was associated with prolongation of the P-R interval.

2. *Aortic Disease.*—Five cases of aortic regurgitation were found in the series. In 2 others aortic and mitral disease were combined. In all these cases compensation was perfect, and in several *the men were doing* very laborious work. In 1 case aortic stenosis was associated with the regurgitation. Radiological and electrocardiographic changes were found to support the clinical diagnosis, though they were scarcely necessary.

3. *Congenital Heart Disease.*—Six cases were detected—2 with patent ductus arteriosus and 4 with septal defects. They were easily determined on the typical murmurs, though characteristic radiological changes were often present. Two of the patients were capable of good physical effort, but the others were either of poor physique and correspondingly incapable of such exertion or had been warned since childhood not to take strenuous exercise.

From the point of view of grouping, cases of proved organic valvular disease or congenital heart disease must be regarded as unsuitable for military service if the instructions to the medical boards are carried out precisely. It is of course perfectly true that many of them are capable of heavy physical work, and there is little doubt that a dock labourer with aortic regurgitation would probably be far more capable of standing up to the rigours of military service than a weedy clerk with a mild grade of effort syndrome. There is therefore some reason for the views put forward by Bourne (1940) in advising that certain of these subjects would be fit for military service. In dealing with the problem, however, from the broader point of view of the nation we must take into consideration the fact that there are great chances of an individual with acquired valvular or congenital heart disease deteriorating within the period of his military service. In such an event it would be difficult to prove that the military service, even when of a selected character (if, indeed, such service exists in the Army), might not have been an accelerating factor and so have rendered him a charge on the nation. Further, it is common knowledge that men with valvular lesions, congenital or acquired, showing perfect compensation for many years, may suddenly and unexpectedly break down with the symptoms of congestive heart failure: they are, moreover, always potential subjects for infective endocarditis.

Hypertension

Seven cases were found in which the principal feature was arterial hypertension. In 6 of these the men had a good cardiac reserve and were capable of playing games. Even in a case in which there was a pressure of 250/110 and accompanying cardiac enlargement and arteriosclerosis the patient played football. When the rise of blood pressure was pronounced or was accompanied by radiological changes or considerable arteriosclerosis the patient was recommended for low grading, but when the rise of blood pressure was moderate—e.g., up to 170 systolic—and there was no rise in diastolic pressure or other evidence of cardiovascular degeneration, further readings were recommended before final grading.

Effort Syndrome

After systolic murmurs this group of cases presents the greatest difficulties. No doubt the obvious cases with constitutional evidence of poor physique, nervousness, tremors, blue hands, and so forth were dealt with by the medical boards, so that the cases referred to here were of the borderline type. In none of the 17 cases classified as effort syndrome were there any pronounced symptoms, and the patients were referred chiefly on account of murmurs or tachycardia, or both.

One of the difficulties is to decide whether cases of tachycardia with little or no impairment of the exercise-tolerance test should be classified as effort syndrome. The line taken was to assume that such minor variations from the normal were due to apprehension at the medical examination, and, providing the patient gave a history of good capacity for physical exertion and presented no other abnormal features, he was recommended either for Grade I, or for Grade II during a period of initial training with the expectation that he might be raised later to Grade I.

All the 9 cases recommended for lower grading were engaged in clerical or similar light work, all showed a poor exercise-tolerance test, and most had systolic murmurs at the apex. Even these cases were not recommended for permanent low grading, but for training with the object of determining their ultimate capacity for physical work and the strain of military life.

Abnormal Rhythms

Two cases were found which gave a clinical history diagnostic of paroxysmal tachycardia—namely, an abrupt onset and offset of tachycardia lasting some minutes to an hour or two. They presented no other signs of organic cardiovascular disease, and the cardiac compensation was good. Nevertheless it was felt that such cases would be so uncertain in military life as to make these subjects unsuitable as soldiers.

In another 8 cases recommended for full service clinical and electrocardiographic measures showed the arrhythmia to be of a harmless variety—chiefly extrasystoles—though in 1 case the pronounced sinus arrhythmia with bradycardia raised a suspicion of heart-block, which was disproved by the electrocardiogram. One case showed a typical pulsus bigeminus confirmed by electrocardiogram as a ventricular extrasystole after each normal beat. In every other way the cardiovascular system was intact, and it was felt that this rhythm was physiological for the individual and should be no bar to full military service.

Cardiovascular Degeneration

A few cases were found in which, for the man's age, there was undue arteriosclerosis, sometimes with slight radiological changes or left axis deviation. For the most part these men were recommended for slightly lower grading, but it was felt that any further changes in the cardiovascular system would be so gradual as scarcely to be modified by a reasonable period of military service.

Finally, it should be mentioned that there were a few cases with disabilities, non-cardiac in origin, but perhaps accompanied by some minor changes in the cardiovascular system—for example, 1 case of doubtful hyperthyroidism, 1 of diaphragmatic eventration, and several of bronchitis with emphysema.

Summary

A brief analysis is presented of 130 recruits referred by Ministry of Labour medical boards for special examination of the cardiovascular system. The difficulties of the systolic murmur and borderline effort syndrome cases are considered, and attention is drawn to occasional radiological and electrocardiographical changes leading to lower grading in patients in whom the clinical signs were equivocal. I have indicated some of my views on grading, but am well aware that in many of the problems presented there is no room for dogmatism. Further, the actual grading is finally a matter not for the consultant but for the medical board.

I am very much indebted to my secretary, Miss K. Wolfenden, for her help in the preparation of this paper.

ALLERGIC ECZEMA AND CATARACT

BY

J. G. MILNER, F.R.C.S.

The eyes are not uncommonly involved in diseases of the skin. The lids, conjunctiva, and cornea may all become affected. Sometimes the ocular disturbance is slight—for example, a mild blepharo-conjunctivitis associated with a dry scurfy scalp—but a much more severe reaction may occur, as in the keratitis accompanying facial rosacea. In this disease there is never rosacea keratitis without facial rosacea, and although local applications in both instances are beneficial the important treatment is that of the underlying metabolic cause. If this can be suitably treated both skin and eyes improve very considerably, suggesting a common origin for the two diseases.

That the conjunctiva and superficial layers of the cornea should participate in diseases of the skin is not a matter for surprise. These structures are ectodermal in origin and would be expected to react to like stimuli. The lens is developed from surface ectoderm also, and, although its extreme modification of structure for the functions allotted to it render it a unique organ of the body, it is not illogical to expect it to respond to such stimuli as well. It could only do this, of course, by becoming opaque.

In fact, however, the lens is very rarely affected in skin disease. The majority of reported cases have been in patients suffering from neurodermatitis or sclerodermia. In view of this rarity, I am prompted to report a case of anterior cataract associated—directly, I believe—with allergic eczema.

Case Report

The patient, a man aged 26, has been subject to attacks of allergic eczema for many years. Only in the last five years have the eyelids and eyebrows been affected. Other allergic manifestations have been asthma and colitis. All sorts of treatments have been tried (including *x*-ray applications to the face and elsewhere), and it is interesting to note that autohaemotherapy is the only one which has given any relief. Several courses of calcium have been administered, as he is deficient in it. His father has similar allergic manifestations, but no eczema

I first saw the patient in February, 1940, when he complained that for three months the right vision had been misty. On examination I found that there were fluffy opacities in the right lens, central in position, just beneath the anterior capsule These opacities were accompanied by several vacuoles Vision was 6/18 with slight correction. The left lens, except for two small vacuoles, was clear. Vision in this eye was 6/6 with a slight correction. It must here be recorded that one week later the right lens was unchanged, but the left had progressed to a state exactly resembling the right, and vision in this eye was 6/18 also. I cannot account for this sudden and rapid increase in the left lens opacities: at the end of June there had been no further increase. Operation was not immediately advised, since, binocularly, he was able to carry on his work without much difficulty. After a few weeks, however, he found his vision varying and he was experiencing increasing discomfort while reading. Therefore, on February 28, 1940, the right lens was needled. A curette evacuation was performed the following day and he made an uneventful recovery. Vision is now 6/5 with correction.

It must be pointed out here that the dose of *x* rays which he had was not enough to cause an irradiation cataract. Further, the latent period was too short and, more important still, the actual appearance and position of the cataract were not such as are associated with irradiation, the features of which I have described elsewhere (Milner, 1934).

Literature

Rothmund in 1868 noted the presence of cataract associated with skin disease. Andogsky (1932) invented the term "cataracta dermatogenes" in the case of a young man with bilateral cataract and simultaneous skin eruption. Kurz (1924) reported a case of cataract associated with eczema in a girl aged 21. This patient had been given *x*-ray treatment, and Kurz suggested that the parathyroids may have been injured, the resulting dysfunction being responsible for the cataract. (It is not clear whether in this case there were in fact signs of parathyroid dysfunction.) Davis (1921) published the case of a girl of 15 who had a stellate cataract situated in the anterior layers of the lens and who suffered from eczema. He thought that the common origin of skin and lens correlated the two phenomena.

Daniel (1935), who quotes the above examples, demonstrated three cases. Two were in girls of 17 and the other in a man of 35. All three patients had allergic eczema and anterior cataract. Daniel suggested that the cataract changes were allergic in origin. Alan Woods, referring to Daniel's cases, suggested that in allergy the lens capsule (an ectodermal structure) participates in the general cutaneous allergic reaction and that its permeability might be altered. But, he says, there are objections to this unless it could be proved that the aqueous contains specific allergen. Woods gave it as his opinion that there was not enough evidence to warrant the term "allergic cataract."

Gronbläd (1940), referring to Rothmund's cases, says that they were probably examples of poikilodermia Jakobi, a rare skin disease which may be associated with cataract. Gronbläd also says: "Cataract has been noted in other skin diseases, but only in sclerodermia and prurigo Besnier (neurodermatitis) is not uncommon." Prurigo Besnier is thought to be allergic. Thomson (quoted by Gronbläd) reported a few cases of poikilodermia Jakobi, one of which had ocular changes—myopia and optic atrophy—but no cataract. In a personal communication Thomson tells me he has never seen a case of cataract associated with eczema, although one was reported to him. Kugelberg (quoted by Gronbläd) said that the term "cataracta dermatogenes" is incorrect. The cataract is not a sequel to the cutaneous changes, but is on a par with them—i.e., "cataracta syndermatotica."

The likelihood of an underlying endocrine dysfunction in most of the types of skin disease that we have under review in this paper is stressed in the literature. Parathyroid disturbances are often found. The association of tetany (parathyroid insufficiency) and cataract is well known, and the cataract accompanying skin disease is said by some to be due to parathyroid dysfunction. This is, however, by no means certain.

Von Szily (1940) says: "Lenticular opacities are observed in those skin diseases which are presumably associated with endocrine disorders—i.e., neurodermatitis,

poikilodermia, and Darier's disease. These cataracta syndermatotica may show very variable pictures; sometimes they appear as anterior subcapsular marginal opacities, sometimes as a typical shield-like cataract, or as a uniform yellow star-like opacity in the posterior cortex."

The exact classification of eczema is not definitely settled. Some include in the term "allergic eczema" all the diseases already mentioned—neurodermatitis, poikilodermia, sclerodermia, Darier's disease, etc.: but others differentiate between a local lesion—e.g., prurigo Besnier, which commonly affects the flexures—and allergic eczema, typified as a generalized rash. If this difference be admitted it will be found that very few cases of cataract have been described associated with generalized eczema.

Summary

The lens is developed from surface ectoderm, and yet very rarely is involved in skin diseases.

Cases have been reported of cataract associated with skin disease, usually neurodermatitis.

Generalized allergic eczema is not the same as neurodermatitis, and a case is reported of cataract—beginning at the age of 26—in a man subject to allergic eczema.

Most cataracts reported have similar features and are situated beneath the anterior capsule.

It has been suggested that cataract formation in these cases is due to endocrine dysfunction (probably parathyroid). There does not seem to be enough evidence to support this. It is suggested that the cataract formation is influenced by the fact that both lens and skin have a common origin from surface ectoderm. The skin is sensitized to produce an eczematous rash and the lens capsule is affected in some way. This defect in the lens capsule disturbs its metabolism and allows opacities to form in the lens subjacent to the capsule.

X-RAY TREATMENT OF INOPERABLE CARCINOMA OF THE RECTUM WITHOUT COLOSTOMY

BY

Ff. ROBERTS, M.D., D.M.R.E.

Examiner in Radiology, University of Cambridge

(From Addenbrooke's Hospital, Cambridge)

The chief characteristics of rectal carcinoma are the early fixation to adjacent organs, the slow rate of growth, and the absence of distant metastases until a late stage in its course has been reached. Hence a very high proportion of its victims are found to be inoperable when first examined, but these have the prospect of relatively long survival, during which their sufferings are due to the local effects of the growth, frequent action of the bowels with a sensation of incomplete evacuation, and the passage of mucus, blood, and gas—symptoms which are more a matter of discomfort and inconvenience than of pain and do not greatly impair the general health. To meet this situation it has become the established practice to relieve the rectum of the necessity of performing its function, by carrying out left inguinal colostomy even though there is no obstruction. I quote from two standard textbooks of surgery published recently:

"Left inguinal colostomy, performed before obstructive symptoms develop, makes the patient's life more tolerable and in many instances causes temporary recession in the activity of the growth. If colostomy is withheld there is a prospect of perhaps eight or nine months of life, but often a life of misery."

"Much relief may be afforded and life prolonged by colostomy, which should not be delayed until there are symptoms of obstruction."

These statements, representative of orthodox surgical teaching, require examination. Does colostomy prolong life? Does it necessarily diminish the patient's misery? Does it retard, even temporarily, the growth of the tumour, and must it be carried out before obstruction occurs?

Does Colostomy prolong Life and lessen Suffering?

The effect on the duration of life has been investigated by Lindahl (1936), who found that among patients who had no other form of treatment the average survival of those with colostomy was 24.5 months and of those without colostomy 19.7 months, these periods dating from the onset of symptoms. Taking into account the operative mortality of 16.8% in non-obstructive cases the value of colostomy in prolonging life appears from these figures to be very doubtful. Moreover, the difference in survival of 4.8 months is largely discounted by the reasonable supposition that cases with colostomy were on the average more advanced than those without and that in some of them colostomy may have been necessary on account of obstruction. Gabriel and Lloyd-Davies (1935), whose figures show an operative mortality of 13.4%, record the survival rates of 238 cases as follows: 50% under one year, 30% under two years, 10% under three years, and 6% over three years, only one patient surviving for more than five years. The average survival is thus about eighteen months.

Does colostomy lessen suffering? Gabriel and Lloyd-Davies state that it diminishes diarrhoea, tenesmus, pain, haemorrhage, and discharge, while improving the general condition. It is true that haemorrhage and mucous discharge may be reduced, but it is equally true that they continue and cause considerable discomfort, while occasionally severe haemorrhage occurs. There is a tendency to represent colostomy life as one of comparative happiness and comfort. No doubt some patients do get on remarkably well under these conditions; but they are comparatively few, and are to be found among the more intelligent members of society and those who can afford the regular attendance of a nurse. However, for the less intelligent and poorer people, especially those living in cramped surroundings, colostomy is anything but a blessing either for the patients themselves or for those who have to live with them. Moreover, the performance of manual work is at least a matter of great difficulty. The contention sometimes advanced that patients actually get to like colostomy is answered by the eagerness of those with a temporary colostomy to have it closed as soon as possible.

Effect of Colostomy on Growth of Tumour

It is said that colostomy retards the growth of the tumour by affording rest to the rectum and by removing the irritation caused by the passage of faeces over the ulcerated surface. The continued functioning of the rectum, it is alleged, increases its blood supply, which favours the growth of the tumour. While it must be accepted that the rate of growth of a tumour is limited by its blood supply, it appears to be well founded that a tumour, through its capacity to form blood vessels and to extract a blood supply from the host, can acquire all the nourishment for its insatiable needs at its growing points. But that the nutrition available for the tumour is appreciably increased by the periodic passage of faeces

over its surface seems to me to be extremely doubtful. Nor is there any evidence for the view that continued functioning of the rectum increases the liability to the escape of metastases to distant parts. By reducing sepsis colostomy is said to delay the formation of adhesions and involvement of the lymphatics. But since the rectum cannot be other than septic, whether functioning or not, it is at least doubtful whether the presence of faeces makes any material difference.

The advantage of resting an organ affected with malignancy is a matter that is often discussed: it is part of the larger question whether a patient with an inoperable growth is better off by living a restricted life of some length or a more active if somewhat shortened existence. In view of the very short prolongation of life afforded by colostomy and the risk of the operation as shown by Lindahl's figures, the loss of a doubtful few months' existence is probably more than compensated by the absence of colostomy. At any rate, this view would probably be taken by the more active members of the community.

When to Perform Colostomy

Finally, must colostomy be carried out when the patient is first seen? Only if it can be established that there is a reasonable fear of obstruction occurring later and that the operation would then be more difficult. This thesis would be very hard to maintain, for the great majority of patients who have no colostomy die of causes other than obstruction, such as secondary growths or septic absorption.

It appears, then, that except in cases of actual obstruction the value of colostomy is very doubtful and that our efforts should be directed to the restoration of rectal function to something approaching the normal. This can be achieved by irradiation by radium or *x* rays. While radium has many successes to its credit it suffers from the rapid diminution of intensity with distance—as much as 20% at 1 cm. depth Colostomy is therefore usually though not always performed. Implantation from above as well as from below would seem to be essential in order to gain access to all parts of the growth without causing damage to neighbouring structures; for we have to deal, as Cuthbert Dukes has pointed out, not with a local growth but with a potentially malignant rectum. Gordon-Watson (1935), while recording the survival of two cases—one for 7¼, the other for 4½ years after radium without colostomy—has shown the limitations of radium, the dangers of its use when secondary sepsis is present and when there is extension beyond the rectum, its tendency to increase pain, and the risk of a fibrous stricture.

X-ray Treatment without Colostomy

In the last five years I have treated inoperable cases by a modification of the technique previously existing. This method I have described elsewhere (Roberts, 1936). It is sufficient to say here that its main feature is the supplementing of the anterior and posterior fields, hitherto used, by two fields on the buttocks and three smaller fields—over, anterior to, and posterior to the anus. By this means the dose delivered to the tumour is greatly increased. Subsequent treatment is given approximately every six months, the amount and interval being determined not by the physical state of the rectum but by its functional behaviour. Thirty-five cases without and 11 with colostomy have been treated in this way. I have thus been able to observe the results of *x*-ray treatment, the value of colostomy, and the effect of colostomy on the response to treatment In attempting, however, to form an accurate estimate I have been considerably handicapped by the difficulty of maintaining an adequate follow-up system under present conditions and by the interruption caused through my absence for several months on military service. Of the 35 patients without colostomy 5 are untraced and several others were traced only to the time when they were no longer able to attend hospital, a difficulty unavoidable in a community which is largely rural. Ten of these patients were in an advanced stage of the disease when referred to me, and survived only a few months. I may say that in the hope that some relief might be given I have refused none, though experience has shown that advanced cases have derived little if any benefit. Of the remaining 20 patients who were followed up and who were in good general health, 6 are still living. Apart from the reasons given above, the average survival time cannot be estimated, since if the living are included this rises to infinity, while if they are excluded the picture presented is erroneously pessimistic. It is not, however, the length of survival but the well-being during survival that matters. All these cases have shown remarkable improvement—in the diminution of the daily motions from seven or eight to one, two, or three a day over a considerable period, in the suppression of blood and mucus, and, in most cases, in the patients' capacity to live almost a normal life. Moreover, since the dosage has not been carried beyond the stage of producing a well-marked erythema there have been no local ill effects. None has suffered from anal stricture and none, so far as I have been able to discover, has subsequently required colostomy. The following cases are worthy of mention.

Case Reports

Case 1.—A compositor aged 54 had three months' history of diarrhoea with slight blood and mucus, six to seven motions being passed daily. Examination revealed a large ulcerated mass in the posterior wall of the rectum. Since treatment blood and mucus have stopped and the bowels are open regularly twice a day. He is doing full work 4 years 6 months since his treatment and 4 years 9 months since the onset of symptoms.

Case 2.—A male old-age pensioner aged 67, working on the land, had one year's history of diarrhoea with blood and mucus, passing several motions a day. On examination there was a large fixed craggy mass surrounding the rectum with a small channel through it. Since treatment he has had three regular motions a day with occasional mucus. He is doing full work 3 years 10 months since treatment and 4 years 10 months since the onset of symptoms.

Case 3.—A carpenter aged 52 had one month's history of diarrhoea with eight motions a day. There was a mass at the recto-sigmoid junction, adherent posteriorly. Since treatment he has passed well-formed motions two or three times daily. He is doing full work 3 years 8 months since treatment and 3 years 9 months since the onset of symptoms.

Case 4.—A mechanic aged 54 had eighteen months' history of diarrhoea with blood and mucus, passing seven or eight motions a day. A large fixed mass was present. Now he has one or two well-formed motions daily and no blood or mucus. He does full work 3 years 9 months since treatment and 5 years 3 months since the onset of symptoms.

X-ray Treatment with Colostomy

In the 11 cases which had colostomy the operation had usually been performed as a matter of routine. One of these patients subsequently had profuse rectal haemorrhage which was stopped by *x*-ray treatment, one developed a prolapse of the colostomy, while nearly all suffered considerable discomfort from the continued discharge of mucus. Although the survival in some cases was long, I am convinced that their state was not improved by colostomy. Nor was their response to *x*-ray treatment improved, but rather the reverse. They may on the average have been slightly more advanced cases than those without colostomy, but I do not think that this difference is sufficient explanation of their failure to respond. The

depressing effect of colostomy has been an important contributory factor, but the chief reason, I think, is the absence of rectal function, which in those without colostomy serves as a valuable guide in the determination of the amount of treatment. Taking a broad view I am convinced that most of these patients would have been happier without colostomy and would probably have lived as long.

Summary of Conclusions

The value of colostomy in non-obstructive cases of inoperable carcinoma of the rectum is doubtful.

Except in advanced cases, *x*-ray treatment provides a method of restoring rectal function to a degree compatible with an active life for a considerable period without resort to colostomy. It has the further advantages of causing the minimum of discomfort and avoiding any operative procedure.

THE VALUE OF VITAMIN B_1 IN DIPHTHERIA

BY

G. E. DONOVAN, M.Sc., M.B., D.P.H.

Medical Officer of Health for the Llwchwr Urban and Gower Rural Districts

AND

M. BANNISTER, M.B.

The Royal Infirmary, Worcester; late Resident Medical Officer, Hill House Isolation Hospital, Swansea

In estimating the value of vitamin B_1 in diphtheria it can be argued that the general population does not receive an adequate amount of that vitamin and that the neglected case of diphtheria comes from a poor or careless home. It is possible that an acute illness may reveal a latent deficiency, and this may be accentuated by the nutriment given in diphtheria, especially glucose. The argument is strengthened by the obvious resemblance between the clinical condition produced by the toxin of diphtheria and that by vitamin B_1 deficiency, as both show anorexia, circulatory failure, and polyneuritis.

We have summarized in Table I most of the published cases of diphtheria in which vitamin B_1 has been used.

The Present Series of Cases

As the published results of the various authors are contradictory it was decided to reinvestigate the problem and check our results by controls. The cases chosen suffered from severe or very severe faucial diphtheria. They were given the usual treatment, such as anti-diphtheritic serum, absolute rest, etc.; but the test cases had vitamin B_1 in addition. The dosage was 4.5 mg. subcutem daily, the total varying from 36 mg. up to 162 mg. Both test cases and controls were given the routine hospital diets. It was considered desirable not to modify the vitamin content of these diets, which consisted of:

The Onset Diet.—Milk ʒvj with glucose ʒj at each meal. Water and occasional orange juice between.

The Continuation Diet.—Milk with weak tea, jelly, rice pudding made with milk, crustless bread and butter, small quantity of fresh fruit.

The Recovery Diet.—Breakfast: Egg sandwiches, tea. Lunch: Cocoa made with milk, plain biscuits. Dinner: Potatoes, gravy, mincemeat, sometimes a second vegetable; rice pudding with milk. Tea: Bread, butter, jam, fresh fruit, weak tea. Supper: Hot-pot and rice, cornflakes or porridge, milk.

TABLE I.—*Published Cases of Diphtheria in which Vitamin B_1 has been Used*

Observer	No. of Cases	Type of Case	Result
Neumann (1935)	2	Post-diphtheritic paralysis	Rapid improvement — more marked than ever before observed
Peters and Cunningham (1937)	10	Severe cases of diphtheria	No effect on incidence of paralysis—2 developed paralysis of ciliary and palatal muscles; 2 others showed additional paralysis of pharynx and diaphragm, both dying. Clinical experience confirmed by experiments on guinea-pigs
Knapp (1937)	2	(*a*) Drunkard with severe diphtheritic paralysis of diaphragm (*b*) Paralysis of soft palate and diphtheritic pseudo-tabes in child 3 years old	(*a*) "A rapid improvement at the very last moment" (*b*) It was possible to relieve all symptoms within three days
Bennholdt-Thomsen (1936)	1	Severe pharyngeal diphtheria in child 4 years old, in addition to extensive paralysis of diaphragm and bronchopneumonia	Improvement after first dose; improvement continued afterwards, so that the disparagmatic paralysis disappeared within a few days
Teofazic (1938)	5	Paralysis of diaphragm	2 recovered, the other 3 died
	31	Examples of paralysis of palate	No effect
	24	Malignant diphtheria	Incidence and severity of paralysis much less than usual
	33	Extensive faucial involvement	
Strnad (1938)	5	Toxic diphtheria with severe myocarditis and polyneuritis	Improvement was rapid and dramatic in all cases
Reach (1939)	1	Severe post-diphtheritic pseudo-tabes with cranial nerve paralysis	Immediate improvement in mental and physical activity, which wore off in a few hours. Paralysis progressed, but diminished after 7th injection
Schiaparelli (1939)	?	Animal experiments	Vitamin B_1 was found to have no prophylactic or therapeutic effect on post-diphtheritic paralysis. At the most it could be observed that paralysis set in later in guinea-pigs treated either previously or simultaneously with vitamin B_1 than in control animals
Hansen (1939)	?	?	Hansen expresses opinion that vitamin B_1 has no favourable effect in diphtheria
Feige (1939)	30 cases and 30 controls	Mixed	Average duration of paralysis in children so treated was 29.6 days, whereas in the controls it was 49 days. Two patients on vitamin B_1 and 5 not on it died
Reinhard and Schwartzer (1939)	17	Routine diphtheria	No appreciable improvement in the paralysis followed treatment with aneurin. Their results were supplemented by estimating aneurin content of urine, which fell in those developing post-diphtheritic paralysis
Kiss (1940)	3	Post-diphtheritic paralysis	Clinical recovery began in a few days and proceeded rapidly
Frey (1940)	13	Severe faucial diphtheria with more or less widespread paralysis	Seven died. Frey believes in the specific action of vitamin B_1 on nerve supply to the diaphragm. Some of those fatal cases showed evidence of improvement in diaphragmatic movements before death

The home conditions of the patients were investigated, as it was hoped they would act as an index of the previous intake of vitamin B_1. The cases are summarized in Tables II and III.

TABLE II.—*Test Cases*

Case No.	Sex and Age in Years	Home Conditions	Patient's Condition	Vitamin B_1	Course of Disease	Result
1	F. 6	Very poor	Very severe	40 mg. from 7th day	Very satisfactory	Recovered
2	M. 11	,,	Severe	110 mg. from 9th day	Palatal and pharyngeal paralysis. Right Bell's palsy and paralysis of legs	,,
3	M. 8	Fair	Very severe	80 mg. from 23rd day	Very satisfactory	,,
4	M. 6	Very poor	Severe	60 mg. from 30th day	Fairly satisfactory	,,
5	F. 6	Poor	,,	36 mg. from 15th day	Very satisfactory	,,
6	M. 6	Fairly good	,,	56 mg. from 5th day	Palatal paralysis on 10th day. Pharyngeal paralysis in 5th week	,,

Conclusions

The impression gained from the series was that vitamin B_1 had neither a prophylactic nor a therapeutic effect on diphtheritic paralysis or the cardiovascular complications of diphtheria. The most that could be claimed was that it seemed to give the patients a sense of well-being, plus an improvement in appetite. The sense of well-being was of doubtful value in those who were acutely ill as it tended to encourage restlessness. Vitamin B_1 helped in the convalescent stage.

Summary

Most of the published cases of diphtheria in which vitamin B_1 has been used are given in tabular form.

The action of vitamin B_1 was investigated in 20 diphtheritic cases of our own and the results checked by 20 control cases. The results are presented in tabular form.

Thanks are due to Messrs. Evans Sons Lescher and Webb Ltd. for help and generous supplies of vitamin B_1.

TREATMENT OF GINGIVITIS WITH ASCORBIC ACID

BY

H. GORDON CAMPBELL, L.R.C.P., L.R.C.S., L.D.S.

Professor of Dental Surgery

AND

R. P. COOK, Ph.D.

Lecturer in Biochemistry

(From the Dundee Dental Hospital and the Department of Physiology, University College, Dundee, University of St. Andrews)

At the Dundee Dental Hospital, during ten weeks recently, 18 out of a total of 505 new patients have been found to be suffering from gingivitis: 14 of these have been treated by us with massive doses of ascorbic acid with favourable results; 4 failed to co-operate.

The clinical features in a typical case are as follows. The patient complains of painful and bleeding gums. The bleeding is usually spontaneous, but is worse when the teeth are brushed. In 10 cases there was marked lassitude. On examination the gums are found to be red and congested. The area involved varies, but in most cases it extends from the gum margin upwards or downwards for a distance of 8 to 10 mm. On pressure the gums bleed readily, the blood flowing freely from the gum margin. In 2 cases severe sloughing of the gum was observed. In spite of the varied types of gingivitis described in the textbooks we have taken as our main criterion of this condition the prompt bleeding of the gum on pressure. This sign is of great value, as it provides a ready means of following the reparative process. In no case could the gingivitis be attributed to trauma, calculus, or the administration of drugs. There were no other gross signs of a pre-scorbutic state.

Treatment

No dental treatment, such as scaling or the use of mouth-washes, was undertaken in any of our cases. On admission the patient is given 300 mg. of ascorbic acid, and a sample of urine is collected approximately six hours.

or at the latest twelve hours, after this dose. The urine is tested for ascorbic acid by the dichlorophenol-indophenol indicator (Roche). This method follows the saturation test of Harris and Ray (1935). It readily enables one to determine the ascorbic acid saturation of the patient. The presence of 5 mg. or more of ascorbic acid per 100 ml. of urine is taken to indicate adequate saturation.

The patient returns for inspection the following day, when a further 300 mg. of ascorbic acid is given. The urine passed after this dose is then tested. Even after one such dose a great difference in the gum tissue can be observed. The pain has largely disappeared, and the red and congested area of gum has shrunk to half the original size. The gums still bleed on pressure. During the first and second days of treatment some patients experience a tingling sensation in the gums. This is probably associated with the reparative process. The treatment is continued for a further four days, or for two days longer than the time it takes to increase the amount of ascorbic acid in the urine to a value of 5 mg. per 100 ml. The amount of ascorbic acid found necessary to saturate the patients has varied from 900 to 4,200 mg. The average dose has been 2,000 mg.

In most cases there is no bleeding from the gums on pressure after four days' treatment. The long-standing cases appear to be more refractory. One patient who had suffered from marginal gingivitis for four years required 4,200 mg. before his gums responded satisfactorily. The statement that no bleeding occurs on pressure must be qualified to some extent, however, by remarking that even after the gum has returned to its normal healthy consistency firm pressure will still provoke some bleeding from the interdental papilla between teeth 2 and 3 (lateral incisors and canines). For some unexplained reason this area heals slowly. It may be that this persistent bleeding is associated with lack of a factor that is capable of restoring capillary permeability to normal. Szent-Györgyi claims that the haemorrhagic lesions in scurvy are in part due to absence of vitamin P (hesperidin). Patients have all volunteered the information that they feel much better in general health, and their appearance certainly bears this out. When the patients are fully saturated and their gums are in good condition they are given a maintenance dose of 100 mg. a day. They return for inspection each week.

During the course of treatment by ascorbic acid no dental treatment whatever is given. We did not adopt the customary procedure of scaling or application of mouth-washes, etc., as we wished to confine our observations to the action of ascorbic acid alone. It is interesting to remark that in 7 cases the state of oral hygiene and of the teeth was very bad indeed.

The results would apparently indicate that lack of ascorbic acid is one important factor in the causation of such cases of gingivitis. The large amounts necessary to saturate the patients are very striking. The disappearance of the lesion with continued administration of the vitamin must be more than purely fortuitous. As long ago as 1930 Hanke advocated the use of massive doses of orange juice in the treatment of gingivitis. He recommended one pint of orange juice daily for long periods—up to a year at least. This amount of orange juice contains approximately 300 mg. of ascorbic acid and possibly other compounds. He attributed his excellent results to the presence of vitamin C. Roff and Glazebrook (1940) have also obtained successful results. They state, however, that marginal gingivitis can be cured by better oral hygiene. Other workers who have reported favourable results of ascorbic acid in the treatment of gingivitis are Kramer (1937), Demoulin (1938), and Herlitz (1939).

Summary

Fourteen cases of gingivitis have been treated with massive doses of ascorbic acid without any other dental treatment such as scaling or mouth-washes. 300 mg. of ascorbic acid was given daily until a urine test showed that the patient was saturated with the vitamin. On an average a total of 2,000 mg. was needed. The previously sore and inflamed gums became normal after approximately four days' treatment. The treatment should be followed by a maintenance dose.

We are indebted to Roche Products Ltd. for our supply of ascorbic acid and indicator tablets.

Clinical Memoranda

Chlorine for Nitric Acid Burns

Burns caused by the strongly corrosive acids, nitric and sulphuric, differ in many ways from heat burns. In the latter the object causing the burn ceases to act when the body is removed from contact, but in chemical burns the destruction of tissue goes on until the corrosive is absorbed, washed out, or neutralized.

Clinically there is a contrast between the types, for the heat burn will show inflammatory reaction within twenty-four hours, while the nitric acid burn may appear unchanged for seven to ten days, giving to the uninitiated a false hope that little damage has been inflicted. During this quiet period the skin in the burnt area retains the deep yellow stain (xanthoproteic reaction) which is formed immediately on contact with strong nitric acid, and it feels leathery, but is neither cold nor the seat of pain. Sensation may be slightly numbed, but neither in finger nor limb, should the burn involve these parts, will there be interference with voluntary movement. At the end of a week, or slightly later, a line of demarcation appears, and necrosis becomes evident, progressing to a slough which separates tediously. Healing is remarkably slow. When extensive areas in the back or hip are burnt, prolonged residence in hospital becomes necessary, and cases have been met with for which nine months of indoor treatment have been required before a succession of skin grafts have brought the patient to the stage of being discharged. In the area of the knee-joint deep necrosis from a nitric acid burn has destroyed the continuity of the peroneal nerve and caused permanent drop-foot. On the cheeks the contraction following the healing of nitric acid burns sometimes gives rise to cicatricial ectropion, calling for plastic surgery.

In view of these facts, which are well known, any treatment which promises to lessen the severity of the corrosive action of nitric acid on the skin is worth recording, and for this reason the following case is reported.

CASE REPORT

A workman was turning an earthenware cock when it sprang from its seating and a quantity of strong acid was splashed with force on to his face. The acid had the following composition: nitric acid, 23.5%; sulphuric acid, 68.8%; water, 7.7%. He immediately immersed his face in the nearby water-butt and continued lavage until he was brought by ambulance to the ward. There the routine treatment of scrubbing the stained areas with methylated spirit and profuse bicarbonate of soda was given. The parts affected were the forehead, almost all of the left cheek, the bridge and left side of the nose, the chin, and scattered areas over the neck. The eyes had been protected by goggles. The intensity of the yellow stain recalled a case ending in cicatricial ectropion. The site of the burn was in both cases similar, as was also the strength of the acid involved. The idea that decolorizing the

stain might serve some purpose was conceived. Ammonia, which is recommended by some, has not in my experience been effective as a decolorizer either on the skin or when applied to material; indeed, the stain of nitric acid is sometimes intensified by the application of ammonia.

Bleaching was thought of and, as a quick method of obtaining harmless chlorine, eusol (Edinburgh University solution) was rapidly made by shaking up eupad with warm water. Swabs of this solution were rubbed on the stained area, decolorization taking place almost immediately. It was surprising how rapidly the stain transferred itself from the tissues to the swab. The friction with eusol was kept up briskly, and was repeated after short pauses until the affected areas assumed a pale lemon colour. A very thin coating of 5% tannic acid solution was then painted on all burnt places by means of a camel-hair brush, and all surfaces were quickly dried by a hot-air drier. During the application of the eusol solution the patient at once voluntarily stated that the smarting and tingling in his burns had gone.

The sequel to treatment was interesting. In less than three weeks the patient returned to work without obvious sign of injury. He had not suffered the slightest discomfort in the face or interference with sleep or appetite from the time of the application of eusol. Two weeks from the date of the accident his doctor had allowed him to visit the barber for a shave.

Xanthoproteic acid is regarded as a perfectly innocuous substance, the colour serving only to mark the extent and intensity of the nitric acid action. It would seem, however, that the rapid removal of this nitro-compound from the skin prevents corrosive destruction of the tissues.

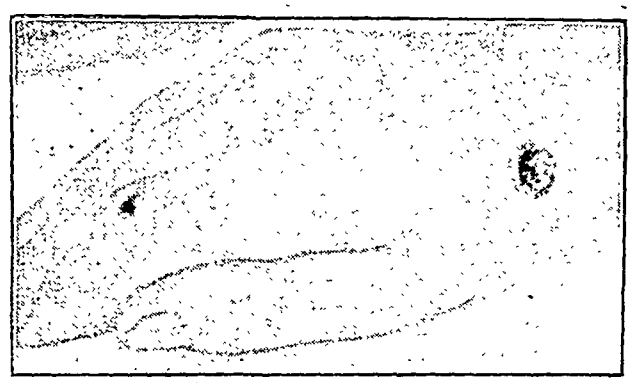
A Case of Cow-pox



It is difficult to determine why cow-pox is so seldom seen nowadays. Perhaps it is considered a trivial ailment and a doctor is not consulted, or perhaps it is a rare disease and therefore rarely exhibited.

An account of an outbreak which occurred in Somersetshire was published by Dr. R. J. Reece in the *Proceedings of the Royal Society of Medicine* in 1921. He drew attention to the absence of reports of cases in both man and animals for over forty years, and concluded that this was due not to the non-existence of the disease but to the fact that observers believed no useful information could be added to the exhaustive investigations of Robert Ceely, published in 1840. Dr. Reece's article serves as a reminder that cow-pox is not confined to bovines but occurs also in horses and other domesticated animals, and in rats, mice, rabbits, guinea-pigs, hens, and ducks. In these the disease is usually produced by experimental inoculation.

Dr. Reece examined 410 milch cows, at several farms, and found that 214 of them were suspected as having or having had the disease. He had not the opportunity of examining all the milkers employed, but of the 44 he did examine 23 were suffering from or had had cow-pox. Definite figures were not given regarding vaccination, but most of the milkers had been vaccinated in infancy, several had been revaccinated, and some had previously had cow-pox. The sites of infection were usually on the hands, and a photograph published in his paper showed an ulcer at the base of the first metacarpal—a position identical to that shown in the photograph reproduced here. One man had a sore which involved the deep structures of his eyeball and led to a permanent defect in vision. Two lads had ulcers on the eyelids, and one of them had vesicles on the dorsum of the tongue, probably due to licking or sucking a sore on his finger.

REPORT OF A RECENT CASE

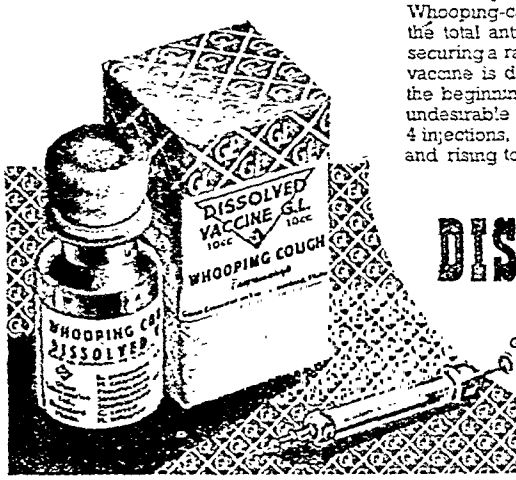
A farm labourer aged 17 had two small ulcers on the knuckles of the index and middle fingers of his right hand and a larger ulcer about the size of a sixpence on the back and outer side of the same hand near the wrist (see illustration). This ulcer seemed as if made by a trephine; the edges were clean-cut, a central core was still adherent, and the core was dark and sloughing. There was a profuse thin yellowish discharge with an offensive smell. The surrounding skin was not inflamed. An enlarged tender gland was present in the axilla, but there was no lymphangitis. Very little pain was felt from the sores. There were no lesions on the body. The disease had been present for over a week when he reported, though he knew that he had contracted cow-pox from a cow's

udder. He could not remember having had any cuts or scratches on his hand. He had never been vaccinated.

The ulcers were cleaned by fomentations, and afterwards dressed with acriflavine. The healing period lasted five weeks, during which time the patient ceased milking but carried on with other farm work. He was vaccinated a week after completion of healing, the result being negative.

COMMENT

There was one other milker of the same herd, and he was unaffected. He had been vaccinated in infancy. The herd consisted of twelve cows: seven were milch cows and five fed suckling calves. All the cows had pox on the udders. There was no pox on any of the calves. As the disease is supposed to be carried from cow to cow by a milker it was hard to account for it in those that were not milked. All the cows used the same shed and grazed in the same fields; the infection may therefore have been picked up from the ground. Sometimes the calves obtained drinks of milk from other than the foster-mother and may have infected the latter that way. The original source of infection of the herd could not be traced; there had been no recent addition and no interchange. The cows had not been examined by a veterinary surgeon, but one "vet" had sent an ointment which cured the disease.



I showed the case to some of my colleagues. Two of them diagnosed correctly; three others were non-committal but concurred when the disease was mentioned. The surprise was that the ailment was not recognized by practitioners with long experience in a rural district. The photograph was taken by Dr. M. C. Cooper.

Polperro, Cornwall. A. MCCLOY, M.B.

The Quarterly Return of Births, Deaths, and Marriages for the thirteen weeks ended June 30, 1940, issued by the Registrar-General, shows an increase in births and marriages in England and Wales. The number of live births was 166,537, an increase of 2,231 over the June quarter of 1939. This is the highest number of births recorded for the June quarter since 1930. Added to the figure of 154,336 births for the first quarter, it makes the total of births for the first half of the year 320,873, which is the highest total for this period since 1931. The birth rate per 1,000 of the population was 16.2. This compares with an average of 15.8 for the second quarters of the five preceding years, and is the highest rate for the June quarter since 1932. There were 48,482 more births registered than deaths. The corresponding increase in the second quarter of 1939 was 43,777. The number of civilian deaths registered in the second quarter of 1940 was 118,055. This was 86,294 below the total for the first three months of the year, and 2,474 fewer than in the corresponding quarter of 1939. The death rate per 1,000 of the population was 11.8, compared with 20.3 for the first quarter of the year and 11.7 for the second quarter of 1939. The report may be obtained from H.M. Stationery Office, York House, Kingsway, W.C.2, price 6d. (by post 8d.).

GREATER CONTROL of WHOOPING-COUGH

Swift antibody response without disabling reaction

Inoculation with Whooping-cough Dissolved Vaccine *Glaxo* enables a large proportion of contacts to escape the disease entirely. In treatment, attacks are rendered mild and brief, and not infrequently are completely aborted. The effectiveness of Whooping-cough Dissolved Vaccine depends on the fact that the total antigens are available immediately on injection, thus securing a rapid antibody response. Furthermore, because the vaccine is detoxicated, it is possible to *give full dosage from* the beginning, even to young children, painlessly and without undesirable reactions. The effective scheme of dosage is 3 or 4 injections, beginning with 0.25 to 0.5 cc., (according to age) and rising to 1 cc.

WHOOPING-COUGH

DISSOLVED VACCINE

In bottles, 5 cc., 10 cc., 25 cc. Glaxo

Glaxo Laboratories Ltd., Greenford, Middx. BYRon 3434

PRODUCT OF THE GLAXO LABORATORIES

Against the Anaemias

Fersolate Tablets contain iron (exsiccated ferrous sulphate) with traces of copper and manganese. The daily dose of 3 tablets is therapeutically equivalent to 45 gr. of Blaud's Pill. One month's treatment is effective in almost every case.

Bottles of 100, 500 and 1,000

FERSOLATE

Ferrolac is a bottle-feed for infants to safeguard against nutritional anaemia. It is a roller-process dried milk-food containing added vitamin D and a therapeutic amount of iron. Fat-modified Ferrolac for the first 4 months. Full-cream for older infants.

1S cn. tins.

FERROLAC

Treatment of pernicious anaemia with Examen Liver Extract has decisive advantages. Examen is highly concentrated in small bulk, each 2 cc. ampoule representing the active haemopoietic factor of 100 gm. of fresh liver. It is protein-free, and injection is painless with no allergic reactions. The painlessness and economy of Examen both greatly ease the burden of lifelong treatment.

Ampoules, 3 x 2 cc., 6 x 2 cc. Phials, 12 cc.

EXAMEN
LIVER EXTRACT

The value of iron to the growing child and the convalescent adult needs no emphasis. Syrup Minadex is a *reconstructive* tonic, containing iron, reinforced by the protective minerals and vitamins which quickly rebuild positive health.

Bottles, 6 and 12 oz. Winchesters 80 oz.

MINADEX

Caldeferrum Tablets present iron, calcium and vitamin D. A daily routine of 4 tablets provides a valuable safeguard against nutritional anaemia during times of increased need, e.g. during pregnancy and lactation.

Bottles of 50, 100, 500 and 1,000.

The Richest Natural Source of Vitamins B_1 B_6 and E

IT is now apparent that when Bemax was first introduced, twelve years ago, in order to combat the prevalent Vitamin B deficiency due to modern methods of "refining" food, the manufacturers were, in fact, building better than they knew. For the increasing precision of nutritional knowledge has shown that Bemax is actually the richest natural source not only of Vitamin B_1 (aneurin), but also of B_6 (adermin) and of E (*a*-tocopherol). In addition, it supplies the other members of the B complex, and is particularly rich in assimilable iron.

Thus the three vitamins which have been shown to play such an important part in the treatment of neuro-muscular degenerations and in maintaining the normal function and structure of the nervous system, exist together in their highest natural concentration in Bemax. The value of Bemax for common constipation has long been recognised, and the physician will not overlook the importance of its high content of Vitamin E in cases of habitual abortion and sterility of dietary origin.

The Vitamin and Mineral Constituents of BEMAX

	Approx. daily human requirement	*One ounce Bemax supplies* weight	% *of daily requirement*
VITAMIN B_1 (aneurin)	mg. 2.0 (666 i.u.)	mg. 1.2 (400 i.u.)	60
VITAMIN B_2 (riboflavin)	2.0	0.9	45
P.P. factor (nicotinic acid)	5.0	1.1	22
VITAMIN B_6 (adermin)	?	richest source	100+
VITAMIN E (*a*-tocopherol)	? 2.5-5.0	7.0-10.0	100+
IRON (available)	12.0	2.7	25
COPPER	1.8	0.45	25
PROTEIN, first class	gm. 40	gm. 9	22.5

Clinical sample of Bemax and literature sent to medical men on application to:
Vitamins Limited (Dept. B.J.), 23, Upper Mall, London, W.6.

Other Products of Vitamins Ltd.

BEFORTISS (Brand) **Concentrated Vitamin B** — *Tablets.* 200 i.u. and 2 mg. per gm. For high dosage of the B complex. *Ampoules.* 2, 10 and 20 mg. For high Vitamin B_1 dosage.

COMPLEVITE Tablets *Vitamin and Mineral supplement.* — To make good the recently revealed deficiencies of vitamins and minerals in the average daily diet.

FERTILOL (*Wheat germ oil*) **Capsules** *A highly active stable source of Vitamin E.* — For the treatment of habitual abortion, dietary sterility and certain neuro-muscular degenerations, etc.

PREGNAVITE Tablets *Vitamin and Mineral supplement.* — To ensure an *adequate* supply of vitamins and minerals to meet the special requirements of pregnancy.

Reviews

DISEASES OF PERIPHERAL ARTERIES

The Diagnosis and Treatment of Diseases of the Peripheral Arteries. By Saul S. Samuels, A.M., M.D., Assistant Visiting Surgeon, Bellevue Hospital, New York. Second edition. (Pp. 372. 31s. 6d.) London, New York, Toronto: Oxford University Press. 1940.

The chief feature distinguishing this from the former edition is the greater prominence accorded to arteriosclerosis as a cause of presenile gangrene. A few years ago, when interest in peripheral vascular disease was so greatly stimulated by the writings of Buerger and the endeavours of enterprising surgeons, no one clinician saw enough cases of peripheral vascular disease to enable him to subdivide them into their proper groups—they all seemed to fit the diagnosis of thrombo-angiitis obliterans. Now that special clinics have been established in which peripheral vascular disease may be more thoroughly investigated it is possible to distinguish between Buerger's disease and the rather commoner arteriosclerotic forms of obliterative arteritis. Furthermore, it is now recognized that these diseases, though having a superficial resemblance to one another, actually differ not only in their pathology but also in their clinical manifestations and their response to treatment.

In this book Dr. Samuels brings out many important points in differential diagnosis, but he could have made the matter still clearer had he written a section on diagnosis from which references to aetiology and pathology could have been excluded. As it is, one is left to build up the clinical picture of Buerger's disease from the given facts about its aetiology, and certain features which distinguish it from arteriosclerosis. We would like heartily to endorse the stress laid upon oscillometry as a method of investigation; and, considering how much valuable information regarding prognosis may be obtained by this simple means, it is surprising that clinicians make so little use of it.

In this second edition as in the first, the author declares his faith in the conservative treatment of gangrene of the toes. In his series of 350 cases of thrombo-angiitis obliterans he has had to perform only one major amputation, and even in arteriosclerotic gangrene, though he admits that amputation through the thigh is more often required, he quotes many examples to show the value of conservatism. The control of pain remains the chief problem when non-operative treatment is carried out, and, though Dr. Samuels makes several suggestions with regard to anodynes, the agony so often associated with gangrene of an extremity may become intolerable and necessitate amputation for its relief.

Unfortunately the book does not give a very clear account of the proportion of cases treated successfully by conservative means, the length of time taken for gangrenous digits to separate, and the liability to subsequent recrudescence of gangrene in the stumps left by these spontaneous amputations. Its chief virtue lies in the clear account of the therapeutic measures which may well be employed in all cases of peripheral vascular disease in the hope that they may be successful—cessation of smoking, postural exercises and rest in the horizontal position, antiseptic treatment of the local lesions, and hypertonic venous infusions—and if these methods were conscientiously adopted there is no doubt they would meet with a very gratifying measure of success. The author maintains an attitude of healthy scepticism regarding the value of elaborate physiotherapy and of surgical intervention, and the records given of his personal experience certainly seem to justify this attitude.

HANS ZINSSER

As I Remember Him. The Biography of R. S. By Hans Zinsser. (Pp. 369. 12s. 6d. net.) London: Macmillan and Co., Ltd. 1940.

The recent holder of the chair of bacteriology and immunology at Harvard Medical School, feeling an impulse to edit a biography of one of his medical friends whose attainments and ways of life bore a resemblance to his own, produced the work entitled *As I Remember Him*, throughout which the friend was referred to by the initials R. S. only, but was otherwise unidentified. R. S. was the writer in chief, but his editor frequently inserted passages of his own, so that the book when first published spoke with two voices. On the death, however, of Prof. Zinsser of the Harvard chair the two voices coalesced, for it was then made known that he and R. S. were one and the same person. No very obvious reason emerges for the original mystification.

Hans Zinsser, as he says in his book, was an American of German origin. Having qualified in medicine he endeavoured in the beginning to conduct general practice along with scientific pursuits, but finally, on being appointed to a full-time post in bacteriology, he was able to devote his undivided attention to his chosen specialty. During his career he held office as teacher or research worker in a number of medical schools, but he is perhaps most widely known by reason of his alacrity in speeding to distant lands for the relief of populations stricken by major infections. In the course of these errands of scientific mercy he visited during the last war Serbia and Bulgaria, and later Poland and Russia. More recently, still following where his aspirations led, he found work to do in Tunis, Mexico, China, and Japan. His travels in these so diverse countries are duly described.

In his writing he often arrests and varies the narrative by the discussion of medical and social questions as they happen to arise. He deprecates as a medical evil the too hasty publication of the results of research by workers more avid of notice than careful of the essentials in such matters. Well-informed and appreciative of French and German language and literature, he believes that the adjustment of the humanities to modern conditions is the root requirement of intellectual training. In the troubled world of to-day he sees that scientific progress has outstripped social development. Being himself without a faith he cannot seek to right the wrongs of the time through any ethical code based upon supernatural authority, but he thinks that the present age may witness a new renaissance with the aid of creative art controlled by enlightened criticism. For his own part his guiding light on his way has been professional tradition, and his reward the pride of service.

Although he claims to have been impressed by the "magnificent pageant" of old Greece, he has permitted himself to write: "We sailed down the coast, passing Corfu, where Nausicaa tried unsuccessfully to vamp Ulysses." Such lapses of taste, which occur from time to time in the book, coming from him are less estranging than they might be from another, for we feel in his case that they cannot proceed from any vein of cynicism but rather that they are the welling-up of the irrepressible flippancy of youth which weakens in most men after that age, but which he was able to keep vigorous far into maturity.

Hans Zinsser was a product of his ancestry and upbringing. He combined the philosophic strain with a

practical turn of mind. He held high ideals but had pleasure in living. He did something towards integrating modern science, but also utilized it in practice for the benefit of his fellow men. His book begins with the question, "Why in thunder should anybody want to write a biography of R. S.?" The answer is writ large in the book itself.

NEUROSYPHILIS

Neurosyphilis (Syphilis of the Nervous System). By C. Worster-Drought, M.A., M.D., F.R.C.P. (Pp. 241; illustrated. 10s. 6d. net.) London: John Bale, Sons and Staples. 1940.

Dr. Worster-Drought's book on neurosyphilis provides in compact and handy form the main facts about all aspects of syphilitic infection of the nervous system. After a historical introduction, which begins by giving Columbus the credit for discovering syphilis as well as America, he discusses the aetiology of neurosyphilis, and his book then follows the accustomed arrangement. There are thirty-one illustrations and over 150 references. The author's treatment of the subject is orthodox, though on a few minor points his views might be disputed: for example, that papilloedema in neurosyphilis is always due to a tumour—that is, gumma—and that general paralysis is commonest between the ages of 30 and 40. The book suffers a little from lack of perspective. Thus the reader might suppose that optic neuritis, papilloedema, and optic atrophy were equally common in meningo-vascular syphilis; and a statement of the relative frequency of the different manifestations of neurosyphilis might with advantage be added to the next edition. These, however, are minor points, and the book will be found a reliable guide by students, and by practitioners wishing to specialize in venereal diseases.

OTO-RHINO-LARYNGOLOGY

A Manual of Otology, Rhinology and Laryngology. By Howard Charles Ballenger, M.D., F.A.C.S. (Pp. 302; 90 engravings and 4 coloured plates. 18s. net.) London: Henry Kimpton. 1940.

Ballenger's *Diseases of the Nose, Throat and Ear,* a well-established and valued textbook originally written by the late Dr. Lincoln Ballenger and now in its seventh edition, forms the basis for this much smaller manual, for which Dr. Howard Ballenger sees a need. The gross reduction in size has been chiefly accomplished by the elimination of all details of surgical technique, with which the original textbook is replete. The purpose of the present book is therefore quite different from that of its parent, which is a book for otologists and laryngologists. This small volume is for students and for those physicians who need a general survey of the subject. In this work, therefore, are to be found excellent accounts of the clinical anatomy, pathology, and clinical manifestations of disease in the regions and organs in question, and also some remarks on their treatment. From the purely medical aspect, which has increased rather than diminished in relative importance during recent times, this has been well done in a manner quite in conformity with the character imposed on the book by the author. There are, however, many occasions upon which treatment assumes an overwhelmingly surgical predominance, and to ignore this or dismiss it in a few words is liable to instil a distorted sense of proportion in the uninitiated.

In what he has undertaken the author has succeeded well, and the omission of surgical detail is his own deliberate responsibility, but there are some purely medical topics which, it must be said, leave much to be desired. This is especially the case with the account of paralysis of the larynx, which is not only obscure and inadequate but is illustrated with misleading pictures. Syphilis, too, may be less important now than it once was, but it deserves more than the scanty description accorded to it. On the whole, however, Dr. Ballenger has produced a book in which the student may browse without being overcome by a mass of detail which he has no opportunity to apply.

Notes on Books

The Gallant Little Campeador, by CECIL HUNT (Methuen and Co., 4s.), is a further tribute to the great work of "the little ships" and will have special attraction for medical men because *Campeador's* navigator was retired Surgeon Rear-Admiral J. B. Muir, M.B., F.R.C.S.Ed., who served in her first with the rank of sub-lieutenant and later as lieutenant, R.N.V.R. The youngest of her four officers was aged 58; Muir, the oldest, was 68, and when two were promoted to lieutenant, Mr. Winston Churchill, then First Lord of the Admiralty, endorsed the recommendation, "Promote them, age will be served." When *Campeador* was sunk by striking a mine on June 22 of last year these four very gallant officers perished with her. This is a short and interesting account of some of their adventures, their good comradeship, and their great work. An obituary notice of Surgeon Rear-Admiral Muir appeared in our issue of July 6, 1940.

Sir William Osler, in looking over the literature of malarial fevers one day, chanced to come across some articles by Dr. John Bassett. He was so fascinated by the charm of these philosophical essays that he was led to collect material for a biography well known under the title of *An Alabama Student,* thus rescuing Bassett's name from oblivion. It was therefore thought appropriate to reprint some of the medical reports from his pen between 1840 and 1850, and this has been done in a highly attractive form. Prof. Elkin contributes an introduction, and an appendix consists of a letter written by Dr. Mastin, a pupil of Bassett's, to Osler in 1896, which supplies interesting information which was lacking when the biography was published. The publisher has generously stipulated that certain profits from the sale of this book should be given to the Harvey Cushing Library at Yale. This is altogether fitting, since *An Alabama Student* was Cushing's favourite gift book. *The Medical Reports of John Y. Bassett, M.D.,* is published at $1.50 by Charles C. Thomas of Springfield, Illinois.

The forty-eighth edition of the *Annual Charities Register and Digest* for 1941 has now been published by Longmans, Green and Co. for the Charity Organization Society. This volume of nearly 500 pages gives details of more than 2,700 institutions and societies. The C.O.S. does valuable work in war as in peace, and it deserves the thanks of those who wish to serve their fellows for producing year by year this classified list of hospitals, charities, and public institutions connected with social services. Copies can be had from the C.O.S., Denison House, 296, Vauxhall Bridge Road, London, S.W., or from the publishers (price 8s. 6d.).

Preparations and Appliances

GENTIAN VIOLET JELLY

Gentian violet jelly B.D.H. (Messrs. British Drug Houses) contains 2% gentian violet and 0.02% sodium ethyl mercurithiosalicylate. It is recommended particularly for the treatment of second and third degree burns of the hands and face. It is generally thought that the usual tannic acid treatment has been found unsatisfactory in this particular type of burn. The manufacturers state that their preparation has an analgesic action and that its use results in a granulating surface satisfactory for the purpose of skin grafting. The mercury compound is added to inhibit growth of Gram-negative organisms because gentian violet acts chiefly on Gram-positive forms.

Eli Lilly and Co. market a similar jelly containing 1% gentian violet with 1:5,000 "merthiolate" (which is the name they use for sodium ethyl mercurithiosalicylate).

HAEMOLYTIC ANAEMIA

Few people have spent their retirement to greater advantage than the late Dr. F. R. B. Atkinson, who was a familiar figure in the library of the Royal Society of Medicine, at his self-imposed task of collecting case reports and bibliographies of rare diseases. The last analysis to come from his pen was one of Lederer's anaemia,[1] and this may profitably be read at the same time as Dameshek and Schwartz's recent review.[2] The acute haemolytic anaemia of Lederer is most common in childhood, but no age is exempt. For no apparent reason the patient becomes markedly pale and exhausted, with profound asthenia, and he may become delirious. The weakness often becomes extreme, with malaise, headache, restlessness and irritability, pain in the back and extremities, fever, and loss of appetite. Gastro-intestinal symptoms are common, and include nausea and vomiting, diarrhoea, pain in the region of the spleen, sensation of weight in the epigastrium, and vague abdominal pain. The rapid onset of anaemia leads to dyspnoea, palpitation of the heart, and oedema of the ankles. The pallor is accompanied by an icteric tinge of the skin or even frank jaundice, but the patient is usually more pale than jaundiced. Haemoglobinuria is present in the fulminating cases, which occur more commonly in infancy. Haemic murmurs can often be heard, the spleen may be palpable, and there may be retinal haemorrhages. Examination of the blood shows a severe anaemia, usually of high colour index, with leucocytosis, reticulocytosis, and the presence of nucleated red cells in the circulating blood. If the condition is untreated the outlook is grave, but if the patient is given one or more transfusions recovery can usually be expected within a few days or weeks.

Dameshek and Schwartz have paid particular attention to the earlier literature, and they show that acute (Lederer) and subacute cases of haemolytic anaemia form a continuous series with the chronic forms of acquired haemolytic anaemia (Banti's haemolytic splenomegaly). This gradation is important, because it suggests that patients with acute and subacute haemolytic anaemias who do not respond to transfusion should be submitted to splenectomy, which in their experience has proved very successful. They have also rediscovered the presence of abnormal haemolysins in the serum of patients with acute haemolytic anaemia, and have demonstrated that the haemolysins disappear after splenectomy, though it must be confessed that the nature of these haemolysins remains very obscure. They have nevertheless presented an interesting schema of the pathological physiology of the haemolytic anaemias. A high concentration of haemolysin leads to fulminating destruction of the red cells, with haemoglobinaemia and haemoglobinuria. Less rapid destruction will be accompanied by bilirubinaemia, spherocytosis, increased fragility, and reticulocytosis. At still lower levels of haemolysin destruction may be balanced by regeneration, and the only detectable abnormality may be a raised level of bilirubin in the serum. This conception is supported by evidence that the red cell population in the haemolytic anaemias can be split up into two groups: the reticulocytes freshly delivered from the bone marrow, and the non-reticulocytes which have been in circulation for some time. The non-reticulocytes are practically all microcytes (spherocytes) and contrast sharply with the reticulocytes, which have a wider diameter but a normal shape. From this it is concluded that spherocytosis and increased fragility represent an alteration in the mature red cell brought about by an intravascular haemolytic agent, and that they are evidence of the pre-haemolytic (prolytic) swelling of the red cell.

This explanation of the erythrocyte morphology in haemolytic anaemia is supported by the experiments of Tigertt, Duncan, and Hight,[3] who injected haemolytic serum into dogs. Haemoglobinaemia and anaemia appeared in these animals, in severity according to the amount of serum administered. In the process of cell destruction the erythrocytes became more spherical, and the approach to sphericity was paralleled by a proportionate decrease in the resistance to hypotonic saline. But a good deal more work must be done on the clinical side before the pathology of the acquired haemolytic anaemias can be put on a satisfactory basis. An urgent need is for follow-up studies to show if recovery from Lederer's anaemia occurs without any sequels, or whether it is not sometimes the herald of a more serious blood disorder or the witness of an underlying constitutional defect. Cases which are observed in the future must be carefully studied if they are to add to knowledge. Essential laboratory data are the size and shape of the red cells, the resistance to hypotonic saline, the evidence of intravascular haemolysis, and the presence of haemolysins in the serum. Two recent accounts are worthy of mention. The patient described by Farrar, Burnett, and Steigman[4] had a haemolytic anaemia of two years' duration which was subject to critical exacerbations. There was no evidence of inheritance and the resistance to hypotonic saline was normal. A haemolysin was detected in the serum and evidence was found of a considerable disturbance of liver function. Splenectomy was successfully performed, and the opportunity was used to take a section of the liver, which showed pigmentary degeneration and fatty change. The anaemia rapidly recovered, the haemolysin disappeared, and the function of the liver returned to normal. Lambie's[5] 18-year-old patient presents a more difficult diagnostic problem, as he had had anaemia and jaundice since birth, and the discussion ranges over the whole gamut of orthochromic and hyperchromic anaemias. Congenital acholuric jaundice is ruled out by the negative family history, the normal shape and resistance of the red cells, and the failure of splenectomy. The condition appears to be a leuco-erythroblastic anaemia persisting after infancy, and a striking feature is its association with hyperuricaemia and severe tophaceous gout.

MEDICINE IN A CHANGING WORLD

The correspondence which followed the publication in the *Journal* of January 18 of Sir John Orr's lecture on "Trends in Nutrition" and the leading article entitled "Medicine in a Changing World" shows, as Sir John points out in a letter in to-day's issue, that at least some readers of the *Journal* believe that the medical profession should make a contribution to planning for the changed world that most of us expect to see after this war is over.

Most of the correspondents were rightly appreciative of Sir John's lecture, and some were highly critical of the leading article. While welcoming criticism, we believe that much of it was based on a misreading of both contributions on a subject which all are agreed is of the highest importance. There was an undercurrent of suggestion that the lecturer and ourselves were in conflict, and that we had called him to task. One correspondent went so far as to suggest that we had been guilty of impertinence, which goes to show that when medical men plant their feet on unfamiliar soil emotion tends to get the better of reason. We do not agree with the correspondent who said that it was the bounden duty of the medical profession to take an active part in political and economic problems, and in this connexion welcome the following statement in Sir John Orr's letter: "The profession would lose its influence if it allowed itself to become the battleground for conflicting political and economic theories. While members of the profession as citizens should be free to hold any political views they think right, the profession as a profession should be apart from, and above, politics. But it should be interested in the promotion of health, and planners should look to it for guidance on the kind of conditions under which the common man would be able to attain his fullest inherited capacity for health and physical fitness. A statement of these conditions based on facts so far as they can be ascertained, would be a scientific, not a political, statement."

This is the crux of the matter, and amplifies the statement made by Dr. A. J. Brock: "I hold that every intelligent doctor is, or should be, a sociologist." Sir John Orr refers also to the "medical charter" which we suggested might be one of the greatest contributions medicine could make to a troubled and war-weary world when the present conflict is finished. There is a body of ascertained knowledge on what is required for proper physical and mental development. There are many gaps to be filled, but enough is known to provide a ground-plan for healthy living. First and foremost comes the important question of nutrition, and the proper feeding of children is a problem which faces the mother from the day her child is born. In a community planned on rational lines such deficiency diseases as rickets and scurvy should be as rare as was disease itself in that enlightened country, Erewhon. The business of the doctor is to lay down, so far as his knowledge allows him, what are the minimum, or better the optimum, food requirements of human beings from birth onwards, and to see that this information is at the disposal of every member of the community. That food is more important in the preservation of health than housing was shown by the late Dr. M'Gonigle at Stockton-on-Tees, but this is by no means to say that housing is not of the first importance. Damp, ill-ventilated buildings which do not provide adequate living room for growing and grown people are a scandal in any country which claims to be civilized. In addition to nutrition and housing there is the vital question of healthy psychological development and conditions in the home, the school, and the workshop. Much of course depends upon the laying of a proper foundation in the home and the school, but upon the maintenance of a healthy environment, both mental and physical, in factories and industrial organizations will depend the true prosperity of this country.

These and a host of other problems need to be sifted out so that the medical profession can give the public a clear statement on what it considers to be the essentials for the healthy life. The task is big enough in itself to discourage medical practitioners from wandering at large about the political and economic field, as some of our readers would have them do. It should be added that we do not criticize the actions of medical men and women who take up politics as a career in the House of Commons; that assembly would be all the better if medical representation on it were increased, and this has been said many times in these columns.

If a charter were indeed drawn up it would be within the competence of those who did the drafting to complete their investigation by estimating the cost of healthy living in pounds, shillings, and pence, as was in fact done by the British Medical Association Nutrition Committee within its limited terms of reference. It would then be for the statesmen and the economists to see that the materials for healthy living were brought within the reach of every man, woman, and child in the country. The task of the medical profession, as we see it, would be to press from a medical platform its recommendations on whatever group of men were in charge of the affairs of the State. As Sir John Orr remarks on another page, "It would give the planners something definite to plan for, and enable them to deal with realities instead of with political and economic theories."

MORTALITY FROM TUBERCULOSIS

The decline in the mortality rate from tuberculosis in the last century in most Western countries tends to overshadow the fact that the disease is still responsible for a large number of deaths each year. Absolutely it is now responsible, as Wolff illustrates with statistics from the U.S.A.,[1] for far fewer deaths than cancer, nephritis, pneumonia, or heart disease. But in making this comparison two points must be borne in mind. First, tuberculosis kills mainly in the prime of life, whereas the mortality from the other diseases is heaviest at a later period. For instance, in the U.S.A. registration area in 1932 two-thirds of the deaths from tuberculosis were of persons between 15 and 50 years old; for the other diseases the figures were: cancer 19%; nephritis 16%; pneumonia 24%; and diseases of the heart 14%. Secondly, tuberculosis is an infectious disease sensitive to the conditions under which a population lives, and likely to increase its striking power materially when those conditions deteriorate. The

[1] *Amer. Rev. Tubere.*, 1940, 42, 1, 214.

involuntary mass experiment of the last war, affecting both belligerent and neutral countries, gave a clear indication of what may well happen in the present one. The association of tuberculosis with poverty has been shown repeatedly. At first sight, however, it appears paradoxical that while the decline in mortality from the disease is greater in the more industrialized countries, and they have now substantially lower mortality rates than the agrarian countries, yet within the same countries it is the industrialized areas that fare worst. The explanation, as Wolff points out, is that in the industrialized countries the standard of living is higher than it is in the agrarian States. On the other hand, within the same country broadly the same standards of living prevail, but the countryman has the advantage of an open-air life, the townsman more frequently the disadvantages of overcrowded and sunless conditions. His detailed examination of statistics in the U.S.A. supports this view. High death rates are generally to be found in the industrial areas, especially those in the north-east. Among the white population mortality rises as density of population rises; yet it is lowest in the most crowded countries of the world. It is not the density itself that matters, Wolff concludes, but the overcrowding, bad housing, and poor nutrition that may be associated with it, which lead to infection with a bacillus that must be regarded as ubiquitous in modern life. Further reductions in the mortality from tuberculosis turn, therefore, upon two factors: improvement in the social and economic conditions of the people, and in the diagnostic and therapeutic measures adopted to find and isolate the open cases which perpetuate the disease.

GALACTOSE TOLERANCE IN JAUNDICE AND THYROTOXICOSIS

Galactose has been used for testing liver function for many years. Introduced by Bauer[1] in 1906, various modifications of the test have culminated in recent methods which estimate blood galactose after oral (Maclagan)[2] or intravenous (King and Aitken)[3] administration of the sugar. This technique appears to be an improvement over the older practice of estimating either urinary galactose or total blood sugar and presents the clinician with a quantitative index of a liver function which is unconnected with the excretion of bile. The advantage of such a procedure in the study of jaundice should require no emphasis, for a glance at the patient is sufficient to indicate abnormal bile formation, and the diagnosis between toxic and obstructive jaundice is more likely to be made by the use of an entirely distinct function. It appears from the two papers referred to that galactose tolerance is usually normal in obstructive jaundice and almost uniformly impaired in toxic jaundice. More work will, however, be needed to establish a useful time limit for the test when employed in this way, for prolonged obstruction must finally affect every function of the liver. A different aspect of galactose metabolism has been raised by recent work on galactose tolerance in hyperthyroidism in which a fairly constant impairment of tolerance has been well demonstrated by the oral technique by Althausen, Lockart, and Soley[4] and by Maclagan and Rundle.[5] While the latter accept the obvious inference of liver damage in this condition and support their hypothesis with much pathological and clinical data, the former ascribe the results entirely to increased intestinal absorption and produce evidence of this in thyroxinized rats. The crucial experiment should consist in a comparison of oral and intravenous methods, but although normal intravenous galactose curves are claimed in patients with hyperthyroidism[4] insufficient details of this work are given, and it is not clear whether the technique adopted would in fact demonstrate hepatic damage; moreover, intravenous tests in thyroxinized rabbits were highly abnormal.[5] The question cannot therefore be regarded as settled, and it may well be that both factors are at work. This obscurity need not necessarily diminish the value of the test in hyperthyroidism, for both sides are agreed on this point. Althausen, Lockart, and Soley are the more enthusiastic and consider the test as reliable in diagnosis as the basal metabolic rate estimation. Maclagan and Rundle are more concerned with prognosis and treatment, but their description of the test as the equivalent of a new physical sign in Graves's disease appears to be justified.

REORGANIZATION IN L.C.C. PUBLIC HEALTH DEPARTMENT

The medical officer of health of the London County Council is in future to be responsible for administering the Council's mental health services. This decision, which was reached at the meeting of the Council on March 4, means the discontinuance of the Mental Hospitals Department as a separate unit, and the transfer of its work and staff to the Public Health Department. The report of the committee which brought forward the recommendation to this effect stated that no dissatisfaction with the past administration of the mental health services was implied. The medical officer of health, Dr. W. A. Daley, had been consulted, and while he did not ask that the work should be transferred to his department, he stated that if it was considered to be in the interest of the Council that he should undertake the added responsibility he would, of course, accept it willingly. No question of altering his salary scale or that of his principal officers in consequence of such transfer of work will arise. It is pointed out in the same report that the Council's mental hospitals and other hospitals have many elements and problems in common, and that while hitherto these have been dealt with by mutual consultation between the two services, there would be considerable advantage in placing under one administrative control both the Council's hospitals for the bodily sick and those for the mentally sick. The present system of administration of the Council's mental hospitals, however, differs from that of the other hospitals in that the former have always been under lay administrative central control. It is considered desirable to maintain such lay control as far as possible. This is proposed to be done by placing the main work in a separate branch of the public health department at the head of which will be a layman with the designation "administrative officer, mental health services," who will be responsible only to the medical officer of health. The medical officer of health must be finally responsible in all matters. The transfer will come into effect not later than April 1.

At the same meeting a further reorganization of the public health department of the Council was proposed and agreed to, consequent upon the retirement or impending retirement of the principal medical officers in charge of two of the three medical branches of the department. The three branches are respectively those concerned with general public health, general hospitals, and special hospitals, each with a principal medical officer with a salary of £2,000 rising to £2,500 in two of the

cases and to £2,200 in the other. It has been decided that the general and special hospitals branches shall be amalgamated and placed under the direction of a principal medical officer, for whom the appropriate salary would be £1,800 rising to £2,000. The name of Dr. R. C. Harkness, chief assistant in the general hospitals branch, is proposed for this position. The position of principal medical officer in charge of the general public health branch has been vacant since the promotion of Dr. Daley to the position of medical officer of health in November, 1939. The duties and responsibilities of the position have been reviewed, and it is considered that an appropriate salary would be £1,600 rising to £1,800. The promotion of Dr. A. M. Hewat, a senior medical officer, to fill this position is recommended.

MEDICAL USES OF ARTIFICIAL RADIOACTIVITY

Radioactive elements have been applied in medicine chiefly as "tracers" in biochemical research and as radiation emitters in treatment. Tuve[1] tells the story of the first "tracer" experiment carried out about 1912 by Hevesy, who left a little radioactive lead with his meat on a boarding-house plate one Sunday, and detected radioactive lead in samples from his meals over the next five days. The radioactive isotopes of an element have the same appearance and the same chemical reactions as their stable (non-radioactive) relatives, so that when combined with substances suitable for feeding or injecting into plant or animal they are handled just like the ordinary compound. Thus the metabolism of any element may be followed, both qualitatively and quantitatively, by the emission of beta or gamma rays by the artificially produced radioactive isotope. The biochemist calls such radioactive atoms "labelled" or "tagged" atoms, and Bale[2] gives an example of how by this means, in an investigation of insecticides, 0.01 μg. of arsenic could be measured in an organ dissected from an insect. Unfortunately the radioactive isotopes of carbon, oxygen, and nitrogen have very short half-lives, so that experiments have to be done at high speed, before the emission of beta rays becomes too small for detection. Even so, radioactive carbon, with a half-life of twenty minutes, is being used in the study of photosynthesis. In the normal dog iron is absorbed from the gastro-intestinal tract in negligible amounts when there is no need for it, but in the anaemic animal it is promptly assimilated in large quantities. If the iron is injected the dog is unable to excrete it. "Labelled" iron appears in the red blood corpuscles as early as five hours after feeding, but it is not yet known whether it is already combined as haemoglobin in this short time. It has similarly been shown that the absorption of phosphorus by rachitic rats is not affected by the simultaneous administration of vitamin D, but the amount retained in the metaphyses from seventy-two hours after feeding onwards is greatly increased in the rats having vitamin D. It will be recalled that the positive line test for calcification in the metaphysis also appears three days after treatment is begun. Artificially produced radioactive substances may be used in treatment in place of radium, and may be particularly valuable in studying the effects of different wave-lengths — for example, P^{32} gives pure beta rays, and Na^{24} gamma rays harder than those from radium. But since different elements are often concentrated in different tissues, their radioactive isotopes may be used for the intimate irradiation of such tissues—for example, iodine for the thyroid. Radio-sodium was used in the treatment of leukaemia by Hamilton and Stone,[3] but as it is not specially concentrated by leukaemic tissue, this was equivalent to total-body irradiation by *x* rays. Now that it has been found that, although the total phosphorus content of leukaemic tissue does not differ from the normal, it has a greater uptake and exchange of phosphorus than normal tissues have, a selective irradiation of leukaemic tissue by means of radio-phosphorus becomes possible. Lawrence[4] reports two years' experience of such a method, in which the effects of ingestion of a single dose of radio-phosphorus have been similar to those of a course of *x*-ray therapy. The maximum dose of sodium phosphate has been 3 grammes, containing up to 8 millicuries of radio-phosphorus, which would be equivalent to about 3 *r* daily whole-body irradiation for a fortnight. It is obvious which method of treatment the patient with chronic leukaemia would prefer if he had the choice. Lawrence has also treated two cases of polycythaemia vera with good result, for radio-phosphorus concentrates in bone and bone marrow, so giving selective irradiation. The dosage has so far been small, but from *x*-ray experience it would appear that 100 mc. or more of radio-phosphorus could be tolerated, which would give a sufficient localized intensity of radiation in bone to destroy multiple myelomata or metastatic carcinomatous deposits.

SURGICAL TREATMENT OF INFECTED PATENT DUCTUS ARTERIOSUS

Ligation of the ductus arteriosus when present as an isolated congenital lesion has been successfully carried out, and in 1939 four cases were reported by Gross.[5] None of these was infected, and it was largely with a view to preventing this fatal complication that the operation was proposed and undertaken. At that time it was doubted whether a case already infected would be suitable for surgical treatment, but A. S. W. Touroff and H. Vesell[6] have operated on four such cases, with considerable success in one. The patients were adult women aged 24 to 63, who had been practically symptomless until infection supervened. There had been symptoms of infection, which in every case was by *Streptococcus viridans*, for three weeks to five months before the operation, and chemotherapy had been tried in three of the patients without effect. On exposing the ductus the wall was found to be inflamed and indurated and firmly adherent to surrounding structures; severe haemorrhage resulted, and two of the patients died on the table from this cause. Friability of the ductus and dilatation of the pulmonary artery increase the risk of such a complication. Of the two patients who survived the operation one was quite well nineteen weeks later, having lost all evidence of infection. In the other case, however, in which the ductus was ligated but not excised, the bacteriaemia was only temporarily reduced, and after four months the patient's condition was deteriorating. It was considered probable that in this case there were also vegetations on the aortic valve from the outset. It is clear that operation on the ductus, difficult enough when the ductus is free from infection, becomes doubly so when this complication has arisen. In recording a single good result out of four attempts, even though it may not turn out to be a permanent cure, Touroff and Vesell have achieved a notable success. It appears that in order to deal surgically with a ductus that has become the seat of a subacute endarteritis from *Streptococcus viridans* it should not be too friable or too adherent, there should be

little dilatation of the pulmonary artery, and the left heart and aorta should be free of infection. These conditions are most likely to be realized if the treatment is undertaken early. Whether or not surgery can remove all risk of subsequent reinfection or, in the case of a vessel not yet infected, can give permanent protection against it are questions that will have to await an answer for some time.

DISTRICT NURSING IN WARTIME

The Central Council for District Nursing in London, which comprises eighty-three district nursing associations, held its annual meeting at County Hall on February 27. The twenty-sixth annual report which was presented described the past year as a testing time for district nursing, but the organization has stood firmly, although finance is difficult. No nurses' home has been rendered uninhabitable through enemy action, and despite the fact that district nurses have to be constantly about the streets, personnel has been spared to a remarkable degree. Two district nurses, however, met their death in raids. At least twenty nurses have been lent to the London County Council for the staffing of rest centres, and many more have made themselves available for duty in emergency. Some nurses have been lent to first-aid posts, where in the circumstances of the last few months they have proved most valuable, and others have been lent, at least for a short time, as a matter of urgency, to air-raid shelters. Strictly speaking, all this is not domiciliary nursing, but it is in the larger sense closely linked to the normal work of district nursing and may provide an even more important opportunity to influence public welfare both now and in the future. In spite of the continuous movement of the London population the number of patients attended under the scheme for public assistance nursing shows no decrease. Among these were 1,591 cases visited for insulin treatment, the number of visits paid during the year being 123,157. It was reported to the meeting that the King Edward's Hospital Fund had, at the Council's suggestion, issued a circular to hospitals urging greater use of district nursing associations with a view to relieving out-patient departments.

TREATMENT OF PHTHISIS

Dr. Peter Edwards's annual report on the work of the Cheshire Joint Sanatorium for the year ending March 31, 1939, again proves that much better results can be obtained in the treatment of phthisis when, in addition to bed rest and a sanatorium regime, extensive but judicious use is made of collapse therapy. During the year 426 patients were admitted, including 122 T.B. minus and 27 observation cases; 20 stayed less than one month, 87 less than three months. One hundred and ninety-two patients were selected for artificial pneumothorax, 87 for phrenic interruption, and 123 for adhesion-section. Tubercle bacilli were "banished from the sputum" in all of the 5 T.B. + 1 cases, in 67% of the 153 T.B. + 2 cases, and in 34% of the 116 T.B. + 3 cases—no mean feat when it is borne in mind that at this institution culture of the sputum is carried out as a routine when no bacilli are detected in smears. Dr. Edwards is reluctant to attach the label "quiescent" to his patients ("As quiescent is difficult to assess we put few in this class"), so that among the sputum-positive group only one patient was discharged as quiescent, though 98% of the T.B. + 2 and over 40% of the T.B. + 3 group are discharged as improved. The paucity of words with which the work of the sanatorium is presented, the questionable importance of some of the tables given (for example, those connected with body weight), and the introduction of second decimals in percentages relating to small numbers further tend to underemphasize sanatorium results that may be considered exceptional in this country. Particular attention must be drawn to the "statistics of ultimate results" in 4,025 patients discharged over a period of one to fourteen years, of whom only 2.4% have not been traced. The report also contains the findings of a comparison between the Vollmer patch test and the Mantoux test with P.P.D. Contrary to some of the claims made by enthusiasts of the patch test it was found that this test could not be depended on to detect all positive reactors and that it was even not a *desirable substitute* for P.P.D. first strength. This investigation cannot carry full weight unless the authors publish the criteria adopted for a positive reaction in each of the tests.

FRIEDLÄNDER LUNG INFECTIONS

Friedländer's bacillus, although more often encountered in chronic infections of the upper air passages, has long been recognized as an occasional cause of lobar pneumonia. Friedländer pneumonia occurs usually in middle-aged or elderly subjects, produces extensive consolidation in which the upper lobe is often included, and has a very high mortality, usually stated to be 70% or more. It is not so well recognized that such cases as survive an acute attack of this disease may suffer from sequelae caused by necrosis in affected parts of the lung. S. Solomon,[1] who three years ago published a series of cases of Friedländer pneumonia, now describes seventeen further cases in which the patient survived four weeks or longer, an arbitrary period adopted to distinguish the acute from the chronic stage of the infection. All but three of the patients were over 40 years of age, all but five were males, and ten were considered to be alcoholics. Only three recovered completely without residual lung damage. The common sequel is lung abscess, usually situated in the upper lobe and draining freely through the bronchi. Such cases present signs of cavitation, often have a blood-streaked sputum, and are hence liable to be diagnosed as tuberculous. History and sputum examination should serve to distinguish them. The earlier the stage at which the sputum is examined the greater the numbers of Friedländer's bacillus and the more certain their significance; with the lapse of time secondary infection is apt to obscure the picture. Four of Solomon's cases were treated with sulphapyridine and one with sulphanilamide; all survived, but none escaped abscess formation. The case described by Surgeon Lieutenant Fraser Sinclair in the *Journal* of February 8 responded well to sulphapyridine and later developed an empyema. The sulphonamides may therefore have some value in combating the acute stage of the infection, but the effect is neither striking nor complete. The surgical drainage of these lung abscesses is not recommended; drainage through the bronchi is free and can be aided by postural treatment. Ultimate complete recovery appears to occur in a few cases. This is evidently a condition to be borne in mind in the differential diagnosis of cavitation in the upper part of the lung in middle-aged patients; it is liable to be confused not only with tuberculosis but also with lung cancer.

MEDICAL PROBLEMS OF A RECEPTION AREA

BY

R. Y. STONES, O.B.E., *M.C.*, M.D., M.R.C.P., D.P.H.

The crisis of 1938 gave us time to make careful preparation for receiving children from danger zones. When war came and the children arrived these plans automatically came into operation, and billets were ready. All went according to plan except the bombing, and many parents, missing their children, fetched them home again. What had not been anticipated, however, was the frequency of nocturnal enuresis among the children, nor were they as clean as had been expected. Faults concealed by maternal affection were not so readily condoned by foster-parents whose beds had been spoilt and their own children infected by these visitors.

Classifying the Children

When, therefore, a new plan of evacuation was prepared a careful history was obtained and a fuller medical examination made, so that the children might be classified as fit or unfit for billets. This scheme worked well with officially evacuated children, but when the *Blitzkrieg* really started many who had not been put in these categories arrived at the centre. Careful preparations for their arrival had again been made: the children were met at a centre, welcomed by committees and officials, rested after their journey, given milk and biscuits, medically examined once again, and drafted to billets. Rather to our surprise, however, a large number were unfit for billeting.

Unfortunately few places were ready for receiving children who were unfit to be placed in ordinary billets. All empty houses had been acquired by unofficial evacuees, by refugees, or by Government departments moved from vulnerable areas. The sick bay which was to serve the whole area was not ready owing to the scant choice of empty houses. The hostel for unbilletable children was nearly full from the previous evacuations. Though hostels had been provided by different local authorities, these were only prepared to accept special cases of a type chosen by themselves. Hours were spent by the medical officer of health in trying to find suitable accommodation for those with such afflictions as scabies, impetigo, and the bed-wetting habit. Also there were contacts with infectious diseases who could not be sent to ordinary billets. A great number of the children, who had been forced to spend long periods in air-raid shelters without ordinary care and cleanliness being possible, were found to be infested with lice and nits. It was impossible to isolate them, so they were sent to ordinary billets and arrangements were made for the school nurse to attend to them as soon as possible. With regard to the former, in the end it was necessary to call upon the Poor Law institutions to accept them while arrangements for their admission were made elsewhere. Here they were kept for a day or two, and were then sent to the hostels which had meanwhile been instructed to receive them. These hostels, not having been prepared for such cases, soon became dirty or overcrowded. Before long, however, steps were taken to correct these defects, and the hostels are now serving a very useful purpose.

Difficulties Met With

Careful thought had been given by the Ministry of Health to the provision by local authorities of institutions for evacuated persons, and Circulars 1871 and 1882, dealing with the matter, had been prepared. Unfortunately these were only suggestions; it had been left to each local authority to adopt them or not, and few of these bodies desired to add to their wartime burdens. Some shouldered the burden nobly, but others took no advantage of the suggestions of the Ministry. Expense had to be considered, and, though this is recoverable, permission to spend was not easy to obtain.

So now, with a lack of these necessary institutions, it is very difficult to deal with problems as they arise. There is the problem of the family bombed out of their home who arrive in this safe area. Temporary shelter must be found at once, and it is gladly provided in public halls and church rooms. As soon as possible billets are given them. Unhappily there are but few left; therefore it is not unnatural that refugees prefer to remain in the halls, where they are fed and made comfortable, and are loath to search for billets.

In this way small colonies come into being, each with health problems of its own. Sanitary arrangements that are adequate for a meeting hall may not be satisfactory when the hall is used for continued residence: washing arrangements are generally scanty, baths are absent, and there is no means of separating the sexes. Minor infectious ailments which could normally be treated at home cannot here be separated from the rest of the community. No room is available for the observation of children, perhaps sickening for a more serious infectious illness, nor can contacts be isolated. A distinct menace to public health therefore arises from the continued occupation of such premises.

A problem which we have not yet solved is the placing of children who have been treated for skin affections and enuresis at the hostel. Foster-parents are naturally chary of accepting such children, and the stigma is hard to remove. Skin affections should be treated in a hostel for minor infectious illnesses, and bed-wetters should first be sent to the sick bay for observation and treatment. It is found that often a change in the type of, and time for, supper, with restrictions in the amount of fluids taken with the evening meal, is enough to check the habit. These children should then be sent back to their former billets, or to new ones, which have been reserved for them for a stated period. Full written recommendations as to diet, etc., should accompany them. Children suffering from frequent nocturnal enuresis, who are apt to block beds in the bay and must be removed, should be sent not to a home for unbilletable children but to a long-term hostel under the control of the doctor and matron of the sick bay, where treatment would be continued.

As billets become scarcer the householder becomes more discriminating and finds a means of retreat by demurring at some condition of the skin of the intended child guest. An abrasion or a labial herpes which has become the site of a staphylococcal infection is given the dread name of impetigo, and so the child is pronounced unfit for billeting and must be sent to the appropriate hostel receiving such skin cases. Difficulty may be found in later placing it in a billet even when the sore is healed.

Suggested Medical Institutions

In this reception area we now have the following institutions: a home for unbilletable children which is also to be used as a sick bay; a hostel for the admission of measles with complications, chicken-pox, etc. (cases of scabies and impetigo are also admitted); two hostels where bed-wetters and mentally retarded children with dirty habits, scabies, and impetigo are admitted. These are administered by three local authorities. In addition to the county fever hospital, which admits all major infectious diseases, there is a disused small-pox hospital, which can

be opened to receive any cases of infectious disease should a major epidemic strain the regular accommodation. In the southern part of the county, and not in this district, two sick bays and one home for unbilletable children are available for the reception of children from this area.

Experience in this rural reception area has shown the need for the following institutions.

1. *Sick Bay.*—It is estimated that about 2% of evacuated children require indoor treatment for minor ailments. Beds should be provided on this scale for *minor non-infectious* illnesses and for convalescents from more serious ones. If enuretics are admitted the proportion of beds would be increased—e.g., to 3% to 4%. All enuretics would be admitted for observation and treatment. According to their response they would be sent either to billets or to a long-term hostel to continue treatment. Private houses are very suitable as sick bays, as they provide rooms for the separation of complaints. All major infectious illnesses would be sent to the fever hospital of the county authority.

2. *A Long-term Hostel.*—This would be under the control of the doctor and matron of the sick bay. A matron or housekeeper, not necessarily a trained nurse, would be in charge. Difficult cases of enuresis and retarded children needing special care would be housed here.

3. *A Hostel for Minor Infectious Diseases.*—Complicated and uncomplicated cases of measles, German measles, whooping-cough, chicken-pox, and mumps would be admitted Also children with skin affections and dirty heads would be treated here as in-patients or out-patients. A trained nurse would be in charge. It would be advantageous to have hostels provided by more than one local authority. It is not unusual for a ward in one of these to be in quarantine through the occurrence of a second infectious illness. This causes difficulty if other accommodation is not available.

4. *A Maternity Home.*

5. *A Short-term Home* for the little children of lying-in mothers.

6. *A Psychiatric Home* for the treatment of difficult children, including some bed-wetters. This institution could serve a large area or, alternatively, could be associated with the sick bay.

7. *A Hostel* where children may be temporarily housed should absence, sudden illness, or other cause prevent the foster-parent looking after the children.

If a hall is required for the use of refugees it should be carefully chosen in advance. It should have separate accommodation for the isolation of suspected cases of infectious illness and contacts: an adjacent small house might be available. Adequate lavatories and washing places, either in the building or close by, are essential.

This list of suggested institutions may seem to be an extravagant one, but it is largely in accordance with the advice of the Ministry of Health. If the health, comfort, and happiness of those who come to us from the danger zones can be better promoted by these means no one would grudge the expense.

The twentieth annual report of the National Executive Council of the British Legion (issued from Cardigan House, Richmond Hill, Surrey) states that during the year ended September 30, 1940, over 4,000 disabled men, war widows, and dependants sought the assistance of the Legion in connexion with claims for compensation from the Government. Constant liaison with the Ministry of Pensions has been maintained. When dealing with compensation claims the medical factor plays an important part, and in 194 cases where there had been a material conflict of medical opinion the advice of eminent medical and surgical specialists was sought. The council records its warm appreciation of those members of the medical profession who have assisted in this way, and also many local practitioners who submitted very full reports on cases.

ORGANIZATION OF RADIOTHERAPY IN WARTIME

The Faculty of Radiologists called a meeting on February 21 to discuss the question of the organization of radiotherapy in wartime, in view of the interruption in cancer treatment owing mainly to the evacuation of population from large centres into areas where the special facilities for diagnosis scarcely exist, and those for treatment, especially irradiation, do not exist at all.

Dr. W. M. LEVITT, who presided, said that a recent census taken by the Faculty of the work done in the radiotherapeutic departments of the voluntary hospitals of London showed that the number of *x*-ray treatments per day on the average was about 176, as compared with 321 before the war. Therefore 45% of the patients previously being treated in these hospitals were no longer coming for treatment. This reduction in numbers was due not to the contraction of facilities but largely to the dispersal of the patients themselves over the countryside. Early in the war the Ministry of Health was asked to take the responsibility for the organization of the radiotherapeutic service on the lines possibly of the E.M.S. The reply was that the Ministry did not regard this as part of its work, and that it was the duty of the voluntary hospitals to make their arrangements to meet the emergency. Later the Ministry agreed to put at the disposal of cancer patients a generous number of beds in E.M.S. hospitals provided that the cost of maintenance was borne by the voluntary hospitals from which the patients would be referred. A scheme for London had been proposed on those lines, and similar schemes for other large centres were under examination. Such a plan would be excellent from many points of view. It would mean that patients at present treated in London would be moved out and treated in safer areas, and that facilities would probably be concentrated in a few places, so that the utmost economy of apparatus would obtain. Two days previously the Ministry of Health had issued a circular (No. 2283), which in a letter was interpreted as follows by an officer of the Ministry:

"All evacuated persons are to be eligible for treatment in E.M.S. hospitals in addition to those persons normally transferred to E.M.S. beds from the town hospitals. Accordingly all these persons will now be brought without difficulty into the hospital system when they need treatment, and all that remains is to ensure that cancer beds to which they can be transferred when necessary are available as required.

It looked from this statement as though the Ministry was prepared to bear the cost of these patients, though it did not actually say so. If it did bear the cost this might furnish a real basis for the solution of their difficulties.

Action of the Radium Commission

Dr. MALCOLM DONALDSON, as a member of the Radium Commission, explained briefly what the Commission had been doing since the beginning of the war. It had told the Ministry that country centres should be started where radium treatment could be carried out in isolated buildings in comparative safety. What Dr. Levitt had just announced might facilitate this development. It had been suggested that three centres should be organized for the London area, and for the rest of the country possibly six. The London area was intimately connected with King Edward's Hospital Fund: the Radium Commission and the Fund had got together, and the Fund had asked the representatives of certain hospitals to meet it to discuss the formation of one centre to start with. His own view was that the centre should be a unit of 200 beds, and that a staff of radiotherapists and possibly surgeons should be chosen from the hospitals which were co-operating in the centre.

Mr. ROCK CARLING said that such a centre must be envisaged as a complete whole. It was not enough merely to move the radium and *x*-ray sets out to the hospital at the periphery, but the staff, including those giving radium and *x*-ray treatment and the specialists in surgery and medicine, must work together as a unit. The physicists must be there, too, for although treatment had been to some extent arrested by the war, research on the physical side had been extremely active. There was one difficulty that he foresaw which was rather

peculiar to radiotherapy. If a surgeon had a patient with tumour of the brain it was a matter of indifference whether he sent him to Queen Square, London, or to Manchester, Edinburgh, or Oxford. But he believed that the radiotherapist up to the present felt a certain amount of reluctance about transferring his case into the care of another radiotherapist who possibly used a method which he did not approve. He hoped that he was mistaken, and that there was in fact in radiology more standardization than he had supposed.

Regional Expedients

A number of speakers from various areas then described the circumstances in their localities. Dr. BOOTH of Wolverhampton said that at first his town had combined with Birmingham in taking over two wards of a hospital in Staffordshire, Wolverhampton having five beds and Birmingham twenty. The radium was kept in a well in the grounds of the hospital, and only such portions of it were brought up as were necessary for daily treatment. For reasons partly financial the joint clinic was given up, and Wolverhampton was now treating patients with its own radium (240 mg.)—another 200 mg. lent by the Radium Commission had been buried—in a reinforced basement block of its hospital. Dr. F. ELLIS (Sheffield) said that at first a centre with twenty-five beds was established about eighteen miles from Sheffield and worked very well for about a year. Then the place chosen became a vulnerable area, and a move was made to another place, where the twenty-five beds for radium treatment were transferred, while the *x*-ray apparatus was taken to the outskirts of Sheffield together with, in a separate building, a ward of ten beds. A further six beds were arranged in the hospital in the centre of the city, the patients being taken by ambulance for *x*-ray treatment.

Dr. B. W. WINDEYER said that the bigger and more pressing problem in London was that of diagnostic centres where it was possible to get hold of the cancer patients in the first instance. He thought also that it would be a retrograde step to set up radiotherapeutic centres divorced from the general clinical and pathological side of hospital work. They had been asked not to use radium for interstitial work, at least in London, and to use radon. But the position of radon supply had been rather desperate. The other day he sent a requisition for radon treatment for two cases of carcinoma of the cervix, and the reply was, "You can have it by April 13." But he understood that the position would soon be a great deal better because of the generous provision of the British War Relief Society, an American charitable organization, of £5,000 for a radium centre in the south of England.

After others had briefly spoken, Lieut.-Colonel A. B. SMALLMAN (Medical Officer, Ministry of Health) described the situation with regard to radium and *x* rays before and after the change in the character of the war in the autumn of 1940. Before that date *x*-ray treatment was being carried on in the ordinary fashion and radium treatment in a restricted fashion owing to the precautions which were taken for the safety of the element. Last autumn a new situation was created. Many *x*-ray departments had to be closed down, and radium treatment was still further restricted. Probably the best thing to be done was to form cancer treatment clinics in hospitals outside the big towns in comparatively safe areas, and of such a kind that by the transfer to them of radiotherapeutic apparatus and staff, the surgeons being already in the hospitals, it would be possible to form real cancer-treatment units. The interest of the Ministry of Health, of course, was not particularly in radium or in *x* rays, but in the whole of cancer treatment. Inquiries to this effect were being made in some of the most badly bombed towns, and were not yet completed. People seemed to wish to go on in the old fashion of separate radium centres. The Ministry was prepared to give whatever help it could, working through the agency of the E.M.S., as indicated in the chairman's announcement at the beginning of the meeting.

Dr. RALSTON PATERSON of Manchester deplored the creation of waiting lists in cancer cases. A delay of six weeks to two months was sufficient to convert a large majority of the curable cases into cases for palliative treatment only. With the exception of some relatively rare cancers, the cancers in which a reasonably high percentage of cases could be cured were those of the skin, mouth, breast, and cervix uteri, and the last was probably the most important because of the manner in which it occurred in relatively young women and usually in mothers of families. In Manchester, since January, 1940, the situation had been met by the creation of a small country unit of twenty beds in which purely radium work was done, and with this it was possible to cope with work represented by fifty or sixty beds, patients being admitted in the first instance to the central hospitals with which the unit was integrated. After bombing started some twenty outside hospitals in North and East Lancashire and Cheshire were used as subsidiary clinics to augment the work of the central clinics, practitioners in the areas concerned were notified, and the loss of patients at the central clinics was largely made good at these outside places, which in peacetime would be too small for the purpose. His general conclusion was that each hospital, voluntary or municipal, and each radium centre must face its own problems and solve them to the best of its ability, endeavouring to keep its own clinics going and to create new ones in accordance with the requirements of cases. He thought they had a claim on the Ministry to help them to meet the additional expenditure entailed, in that the cases were as much casualties of war as those which were due to direct enemy action.

SHORTAGE OF DRUGS

MINISTRY OF HEALTH'S STATEMENT

Certain drugs are now scarce or unobtainable as a result of a number of causes arising out of the war. Many such drugs can be replaced by others which are in plentiful supply and have substantially the same action. The Ministry of Health and the Department of Health for Scotland therefore urge doctors to refrain from ordering or prescribing any scarce drug for which a satisfactory alternative is available. For the guidance of the profession, a report of the Therapeutic Requirements Committee of the Medical Research Council will shortly be issued, containing recommendations on the replacement of scarce drugs by others with equivalent action.

Defence Regulation

As a further step, a Defence Regulation has been made empowering the Minister of Health and two Secretaries of State (acting respectively for Scotland and Northern Ireland), after consultation with the Medical Research Council, to make Orders dealing with the replacement of scarce drugs by alternatives having substantially the same therapeutic action. The general effect of any such Order will be to authorize a chemist who receives a prescription including a scarce drug to supply instead the alternative named in the Order. Any such Order will not apply if the doctor expressly writes against the scarce substance in the prescription the letters "N.A.," or words indicating that no other substance is to be used or supplied in lieu of the scarce substance.

Potassium Salts

An Order has now been made under these powers authorizing the replacement of potassium bicarbonate, potassium bromide, potassium iodide, and potassium citrate by an equal quantity of the corresponding sodium salt, subject to the right of the doctor, as already mentioned, to give a special direction that no alternative is to be used. Further Orders will be made from time to time as required.

Economy in Use of Squill

With a view to conserving the available supplies of squill, doctors are asked to refrain from prescribing squill in all cases where its use cannot be said to be essential. The principal galenicals containing squill are: Acet. scillae, ext. scillae liq., oxymel scillae, syrup, scillae, tinct. scillae; and the strictest economy should be exercised in the use of these preparations.

The committee recently set up by the Ministry of Health to prepare a War Emergency Formulary has under consideration the question of mixtures and linctuses containing preparations of squill, but, pending the issue of revised formulae, a doctor

when prescribing by title only a mixture or linctus containing squill should consider whether the squill is essential, and if he decides that it is not he should indicate on the prescription that the squill should be omitted. The following are the more frequently prescribed preparations containing squill:

Mist. diuret. N.F. contains acet. scillae.
Mist. expect. alk. N.F. contains ext. scillae liq.
Mist. expect. nig. N.F. contains ext. scillae liq.
Mist. ipecac. c. scill. N.F. contains ext. scillae liq.
Mist. senegae ammon. N.F. contains ext. scillae liq.
Linct. scillae co. B.P.C. contains oxymel scillae.
Linct. simplex N.F. contains oxymel scillae.
Mist. oxymellis N.F. contains oxymel scillae.
Mist. scillae co. N.F. contains oxymel scillae.
Linct. morph. rub. N.F. contains syrup. scillae.
Mist. tuss. rub. N.F. contains syrup. scillae.
Mist. digitalis c. scill. N.F. contains tinct. scillae.

AMENDMENTS TO THE BRITISH PHARMACOPOEIA

An official notice appeared in the *London Gazette* of February 28 concerning alterations and amendments to the *British Pharmacopoeia, 1932*, whereby a number of medicines and compounds and the directions for preparing some of them are modified. These amendments, made by the General Medical Council, became official from the date of the publication of the notice in the *London, Edinburgh, Belfast,* and *Dublin Gazettes*. Briefly stated they are as follows:

Cataplasma Kaolini: Poultice of Kaolin. Sodium lactate (70%) may be used, in place of glycerin, in making this poultice. When sodium lactate (70%) is used the formula is modified so that 425 grammes of the sodium lactate replaces the same weight of glycerin; and the directions for mixing the ingredients are varied accordingly.

Sodii Lactas: Sodium Lactate. Sodium lactate (70%) for the above purpose may be prepared by addition of sodium hydroxide or sodium carbonate to a hot dilute solution of lactic acid, and subsequent concentration. It contains 70% w/w of $C_3H_5O_3Na$ (limits, 68 to 72), and about 20% w/w of water.

Scilla: Squill. When squill is prescribed, or demanded, Indian squill may be dispensed or supplied.

Acetum Scillae: Vinegar of Squill. Indian squill may be used, in place of squill, in making this vinegar.

Oxymel Scillae: Oxymel of Squill. Indian squill may be used, in place of squill, in making this oxymel.

Tinctura Scillae: Tincture of Squill. Indian squill may be used, in place of squill, in making this tincture.

Indian squill is the bulb of *Urginia indica* Kunth, divested of its dry membranous outer scales, cut in slices, and dried. When powdered it is very hygroscopic and should be kept in a desiccated atmosphere. Doses: Metric, 0.06 to 0.2 gramme; Imperial, 1 to 3 grains.

Valeriana: Valerian. When valerian is prescribed, or demanded, Indian valerian may be dispensed or supplied.

Tinctura Valerianae Ammoniata: Ammoniated Tincture of Valerian. Indian valerian may be used, in place of valerian, in making this tincture.

Indian valerian consists of the dried rhizome and roots of *Valeriana wallichii* DC. *It contains not more than 2% of other* organic matter. Doses: Metric, 0.3 to 1 gramme; Imperial, 5 to 15 grains.

Appendix VI: Quantitative Test for Lead. In the table on page 558 of the *British Pharmacopoeia, 1932*, insert:

Sodii Lactas	12	5	2	5	10	10

Appendix VII. Quantitative Test for Arsenic. Add the following method:

Sodii Lactas .. .. Limit, 5 parts per million.
Treat 2 grammes as described under "Potassii Acetas."

Third Addendum to the British Pharmacopoeia, 1932. Correction, page 15. Mepacrinae Hydrochloridum, Mepacrine Hydrochloride. The statement of doses should read:

Metric	Imperial
0.05 to 0.1 gramme	¾ to 1½ grains

U. J. Wile and H. H. Houman (*Arch. Derm. Syph.*, 1940, **42**, 587) record two cases, in men aged 52 and 58, of generalized herpes zoster associated with lymphatic leukaemia, of which the first example was described by Fischl in 1914. This association is most frequent in middle-aged men.

Reports of Societies

INJURIES TO PERIPHERAL NERVES

A meeting of the Orthopaedics Section of the Royal Society of Medicine was held on February 22 for a discussion on "Injuries to Peripheral Nerves."

Mr. S. L. HIGGS, in taking the chair, said that the treatment of peripheral nerve injuries had, owing to the war, become of first-class importance. It was true that much research had been done on nerve grafting and regeneration during the last few years, but the practical problem of restoring the nerves remained much as it was left at the end of the last war. It was very necessary to recall the lessons which were then learned.

Mr. W. ROWLEY BRISTOW said that injuries to peripheral nerves, relatively unimportant in peacetime, took an altogether new position in war, and it had been thought well that these cases should be segregated. The segregation was at present mainly in three centres, but if casualties increased every orthopaedic centre would get its fill of this work. It was necessary for the older surgeons to cast their minds back for some twenty years in order that some elementary mistakes should be avoided. It was impossible to keep these patients in hospital during the whole of the long period required for recovery of nerve function; therefore arrangements were being made to have them re-examined by the surgeons and physicians who handled such cases in the last war, and an effort would be made to follow them up and have them back at their original centres for re-examination at intervals of two months or so.

The material under review at one centre at present comprised 145 cases. Injuries of the ulnar nerve predominated, followed closely by injuries of the musculo-spiral and median, and then of the sciatic. Up to date only twenty-three of these patients had been dealt with by operation. During the period of observation treatment was divided into postural and that directed to aid nutrition. In postural treatment the relaxation of the paralysed muscle, with which they were all so familiar, was carried out. There was only one proviso—namely, that they must not keep the hands stiff in a case of musculo-spiral palsy. In sciatic nerve injury there were two deformities to be considered from the point of view of postural treatment—namely, fixed flexion deformity of the interpharyngeal joint of the great toe, and foot-drop.

In treatment directed towards aiding nutrition they worked on the ordinary lines—heat, massage, electrical stimulation, re-education, and exercise. How far was electrical stimulation of muscles of real value after complete division of the nerve? His mind was not made up on this point. On the physical side no treatment of this kind had any effect on the rapidity or completeness of the regeneration of the nerve, but on the psychical side it did make a difference for the patient who had a paralysed limb to see his muscles contracting and relaxing and to see a joint which had appeared paralysed and dead moved again by the action of his own muscles, encouraged by the masseur.

Principles of Operation

With regard to the time of operation (Mr. Bristow continued) it was laid down by the Medical Research Council after the last war that no period was too long to preclude the possible regeneration of the nerve. J. S. B. Stopford of Manchester, in the *British Journal of Surgery*, 1922, published the results of resuture of injured nerve in cases in which the primary suture had failed, and his conclusion was that if a period of more than three years had elapsed since the time of the injury suturing was not worth while, but that it was worth while at any time up to two years. Harold Stiles, writing in one of Sir Robert Jones's books at about that time, said that he always felt it was wiser to operate early, and, as a rule, in cases in which he had waited a long time because they were showing some evidence of early regeneration he found when ultimately he had to operate that it would have been better

if he had operated sooner. A consensus, therefore, favoured early operation, as soon as circumstances permitted.

Repair was effected by end-to-end suture. He stressed the need for very wide exposure. The ulnar nerve could be exposed from the wrist to the axilla, and the freeing of it, in his experience, had never resulted in any ischaemia. Before operating it was essential that the surgeon should know a good deal about the patient. This was not a question of walking into the theatre to perform a technical exercise. One must be prepared to examine the nerve with a faradic battery or condenser discharge apparatus at the time of operation. In operating on a mass of scar tissue one would sometimes be not too certain which nerve was which, and the faradic apparatus would be of great help in differentiating.

The question of neurolysis and the freeing of scar was one of mobilization. It was a matter not of peeling off a sheath, but rather of freeing the nerve from the scar tissue which was pulling on it and irritating it with every movement of the limb. The great majority of nerve grafts in the last war had failed. Since then work had been done on the facial nerve in which the value of graft had been proved. He personally had an open mind about grafting, but it was certain that the autogenous cable graft was to be recommended. It was possible that the new method of suture by fibrinogen in plasma might make a difference. Imperfect recovery of function and sensation was almost invariably found in the most favourable cases after secondary suture or resuture, but, as Farquhar Buzzard had said, even when injuries to the nerve involved complete division they might in favourable circumstances be successfully treated in so far as a certain degree of usefulness was retored to the limb. If, however, the parts affected were needed for highly specialized work or sustained effort they were almost certain to be found wanting.

Disturbances of Function

Dr. J. ST. C. ELKINGTON said that from the clinical point of view lesions of peripheral nerves constituted a number of clear-cut and uniform pictures. He discussed them under the headings of motor, autonomic, and sensory functions. In the case of motor function he pointed out the necessity for differentiating clinically between anatomical severance of the nerve and a state in which the fibres were temporarily out of action without being divided. In many cases it was possible, even in the early stages, to make a fairly accurate guess whether the motor fibres of a peripheral nerve were truly divided or merely out of action. With the undivided nerve the tone of the muscle very often did not disappear completely, and the degree of wasting was much less. But sometimes the two conditions could not be distinguished clinically, and it was here that electrical examination was important. Another point in motor function was the relative vulnerability of the different types of fibres in a mixed bundle. The motor fibres appeared to be exceptionally receptive of injury, and might lose function while sensory nerves retained it, a fact which had led many to regard some conditions, wrongly, as functional.

Autonomic disturbances were particularly to be seen in the skin, but also in the subcutaneous tissue. The most conspicuous was loss of sweating; another was an increase in the growth of hair in the affected part. There was a decrease in the normal power of healing of the tissues. In long-standing cases there might occasionally be seen a marked osteoporosis in the bones of the affected limb. Derangement of sensory function was usually found distributed in two ways, the more important being diminution or loss of one or more varieties of sensation, and the other, spontaneous sensation in the absence of adequate stimulus. In any given mixed group of nerves the area of total sensory loss was very much less than the area anatomically supplied by the nerves. During the recovery of sensory function the first step was generally the return over the completely anaesthetic area of crude sensation, followed by a gradual shrinkage of the abnormal area as normal sensation advanced.

Pathological Aspects

Dr. J. G. GREENFIELD said that almost everything depended on the bridge between the two ends of the divided nerve; this was true in cases of complete division of nerve fibres even when the sheath of the nerve was not damaged, as in bruises. Even under ideal conditions, such as animal experiment, it was out of the question to expect the nerve fibres growing out from the upper end to reach the corresponding nerve fibres at the lower end with which they had had contact before, because there was always in division a very intricate neuroma with numerous axons coming off; similarly there was branching of the old nerve channels from the lower end. Nevertheless, owing to various factors, including re-education, conscious and unconscious, the end-results might be fairly good. In this bridge of the gap there was considerable delay while the nerve fibres were finding their way through the complex neuroma to the peripheral end. It was remarkable how long these peripheral channels remained in perfectly good condition for receiving the new nerve fibres. For as long as two years they could accept the nerve fibres and conduct them to the end-organs, and that was one of the hopeful points about nerve grafting.

Mr. JOCELYN SWAN, speaking about the time to operate, said that in the last war they learned to place very great reliance on condenser discharge reactions. A nerve which did not show any change in voluntary response might show a definite change in response to electrical stimulus. That led to delaying the operation in many cases, and in a number of these it had been possible to see return of function without operation. In his view no nerve case should be operated upon for five or six months after the injury, nor for two and a half to three months after the wound was soundly healed and the condition had become satisfactory. At operation a wide exploration of the nerve should be made, particularly above and below the region of injury. He condemned any suture which went through the nerve. All nerve sutures should be done in a perineural operation with the finest thread that could be obtained. With regard to end-results, it was not possible in the last war to get anything like a good follow-up, but he was able to follow a number of cases for a year or eighteen months, and had had many letters from patients. Best results were obtained with the musculo-spiral nerve. He did not think the patient with a median-nerve injury ever completely regained the sensibility of his fingers. With the sciatic nerve the results were not good. Better results were obtained with the external popliteal than with the internal.

Dr. GEORGE RIDDOCH said that one serious defect in the treatment and repair of patients in the last war was in follow-up and after-care. The Medical Research Council was now planning an adequate follow-up of a sufficient number of cases, at least one thousand, over a period of five years. Adequate occupational therapy would be introduced at the centres, and when the patients were discharged he hoped there would be a scheme whereby they could obtain what physical treatment was needed. A man ought to be placed for treatment as near his home as possible and as soon as possible. The initial distribution of patients before actual treatment was started should be made with a view to the convenience of the subsequent follow-up. The plan proposed would include the employment of research workers.

SERUM TREATMENT OF DIPHTHERIA

At the last meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, with the president, Dr. R. H. MICKS, in the chair, Dr. R. A. Q. O'Meara and Dr. C. J. McSweeney read a paper on the serum treatment of hypertoxic diphtheria.

Dr. O'MEARA compared the clinical results from diphtheria antitoxin now obtained with those of the earliest days of its use, showing that matters were worse rather than better, and that some essential factor had been missed out in the process of development of antitoxin. He advanced a new conception of the nature of diphtheria toxaemia and the specific treatment required to combat it. The toxin, he said, was composed of two substances, one of which (A) was highly lethal to the guinea-pig and present in large amounts in Park-Williams No. 8 toxin as prepared in the laboratory. It had been assumed that hypertoxic diphtheria was due to the production of this substance in excessive amounts, but in actual fact little of it was found in the human patient. Conversely, laboratory toxin contained relatively little of the second con-

stituent (B), but it was this substance which determined hypertoxic diphtheria. "B" promoted the penetration of the tissues by "A," and, in excess, led to a great increase in the size of the local lesion, in the gelatinous oedema around it, in the amount of necrosis, and in the tendency to wasting and paralysis. Ordinary antitoxin contained a high proportion of the antibody to A, but relatively little of that to B. On the administration of antitoxin clinically, therefore, B was not neutralized and the antitoxin was rendered non-avid, dissociation of toxin from antitoxin took place on dilution in the body, and the toxaemia continued unabated. Antitoxins rich in the antibody to B were required for the treatment of diphtheria toxaemia.

Dr. C. J. McSWEENEY recapitulated the clinical manifestations of hypertoxic diphtheria: faucial oedema which might even simulate quinsy; rapidly developing cervical cellulitis involving the whole of the tissues—so-called "bull neck", albuminuria beginning after the fourth day and persisting for two, three, or four weeks; subcutaneous or submucous haemorrhages (in the most severe toxaemias only); fall in blood pressure, most marked just before the onset of symptoms, and cardiovascular failure on or before the tenth or twelfth day. He then classified under four grades all cases admitted to Cork Street Hospital. In Grade I the membrane was confined to the tonsils, or was purely laryngeal, and took the form of speckling, spotting, or scattered patching. In Grade II there was a coherent patch of membrane not involving the palate, or in the larynx with faucial lesions not extending over the pillars. In these cases toxaemia was present and paralytic sequelae not uncommon. If death occurred in either of these grades it was due to some intercurrent cause, not toxaemia. In Grade III the membrane involved the palate, with or without investment of the uvula and or nasal discharge. Toxaemia in this grade was considerable, and there was usually much faucial oedema, bull neck, and multiple paralyses. These cases constituted fully 75% of the "gravis" diphtheria problem. In Grade IV there were toxic haemorrhages from mucous membranes and into subcutaneous tissues, with bruising at the site of injections, associated with lesions in the nasopharynx and much oedema of the throat. Toxaemia here was extreme and cardiovascular failure inevitable when commercial antitoxins were used. Multiple paralyses were almost inevitable in survivors, and these cases constituted the remaining 25% of the "gravis" problem. The grades represented stages of the process of circumferential spread of the membrane. In hypertoxic diphtheria all stages might be gone through within twenty-four or thirty-six hours. The degree of toxaemia was indicated by the sum of the two factors: extent of membrane, and oedema. No anxiety need be felt about paralyses in Grade II cases if commercial antitoxin were given reasonably promptly. For some reason, once the membrane crossed the faucial pillars dangerous cardiovascular sequelae were to be expected. The case fatality was 1% or less in Grades I and II; nearly 16% in Grade III; and nearly 50% in Grade IV. In April, 1940, a small quantity of Dr. O'Meara's avid serum rich in anti-B factor had become available for use in eight Grade III and eight Grade IV cases. The first four were given maximal doses corresponding to those of commercial antitoxin; the remaining twelve were given from 16,000 to 40,000 units each. Only one death occurred, a case mortality of 6.2%, as compared with the 50% anticipated in this type of case. After relating four case histories Dr. McSweeney summarized the difference in clinical behaviour as follows: none (except the fatal case) showed early or late cardiovascular failure; the clearing of the oedema and membrane was much accelerated; there was little or no albumin in the urine at any time; only a few paralytic sequelae were observed; the bull neck often disappeared within forty-eight hours of administration of the new serum; and there was no appreciable fall of blood pressure but, indeed, in some cases a rise.

After the anti-B factor serum had been used up, twenty consecutive Grade III and IV cases had been treated with serum taken from the same horse, only at a much later stage, when little or no anti-B factor was present—thus corresponding with commercial antitoxin. The case fatality rate had been 40%. The clinical proof of Dr. O'Meara's thesis appeared to be complete. Unfortunately serum rich in anti-B factor was not at present available.

Prof. HENRY MOORE characterized this as a monumental communication. Dr. A. R. PARSONS asked why Dr. McSweeney had drawn the line at 120,000 units; he himself never gave more than 100,000 units. He asked where the limit should be drawn, and if the serum neutralized in the same way as an alkali did an acid. Dr. T. O. GRAHAM said that the toxicity of diphtheria in Dublin was very high compared with other parts of the world. The variability in antitoxic properties of sera was probably due to varying amounts of B antibody. Dr. J. McCANN asked if it was now wise to give large doses of streptococcal serum in cases complicated by a secondary streptococcal infection. Dr. W. R. F. COLLIS asked if convalescent serum had been tried, and if suprarenal extract had been used to tide patients over the critical stage of fall of blood pressure. Prof. L. ABRAHAMSON said that he had recently become aware that diphtheria mortality was creeping up and that serum was losing its efficacy in some cases. Prof. HANS SACHS stressed the fact that the pharmacological action of diphtheria serum was not really helpful from the human point of view, though it had antitoxic value as a serum. He wondered if the problem of avidity were really related to the B toxin. Some substances which intensified the action of toxin also intensified the action of other toxins, and the bacilli might produce not the real toxin but a pro-toxin. Dr. BRENDAN O'BRIEN asked if in Grades III and IV there were any cases known to have been immunized by the ordinary methods available. Dr. OLIVER FITZGERALD asked if the B substance could be removed and A only injected; if so, would there be no reaction at all? Dr. ALAN THOMPSON asked whether in the first thirty-six hours there would be better results from using a mixture of avid serum and ordinary commercial serum, providing both anti-A and anti-B substances.

SCOTLAND

Orthopaedic Care in Scotland

In an address to the Edinburgh Women's Luncheon Club on February 19 Dr. J. M. Mackintosh, Chief Medical Officer of the Department of Health for Scotland, said that when the war came to an end some of the very large number of hospitals which the Department of Health had built and had taken over would have to be used for pensioners and some would be absorbed in meeting the shortage of beds which had been notorious in the general hospitals for many years past. With those that remained he hoped something more creative would be done, and he suggested that some part of these beds should be devoted on a regional plan to the care of crippled children. In England there were over forty voluntary orthopaedic hospitals, many of them with a number of clinics served from the centre. In Scotland there was one hospital, the Princess Margaret Rose Hospital, which had developed an orthopaedic system on the English model, and there were one or two municipal hospitals doing orthopaedic work, but in general very little had been done for the crippled child. Four first-class country hospitals were wanted for chronic orthopaedic cases. The hospital by itself, however, was not enough; the early discovery of the cripple, diagnostic facilities, and various kinds of care were also needed.

International Control of Disease

Sir Alexander Russell, who until recently was Public Health Commissioner with the Government of India, lectured at Dundee on February 24 on the international control of disease. He described the setting up of the International Office of Public Health with its headquarters in Paris and the framing of the first International Sanitary Convention in 1912. He referred particularly to the new aspect in international control since air traffic began to make it possible for infected persons and insects to be transferred thousands of miles within the incubation period of many of the dangerous infectious diseases. An air convention was adopted in 1934 whereby, in countries where plague, cholera, and small-pox were endemic, passengers leaving by air were required to be in possession of recent

inoculation and vaccination certificates. Under the terms of the convention every country was required to notify particular aerodromes as its ports of entry for air traffic, and these aerodromes had to comply with certain requirements before they could be classed as "sanitary." Until the fall of France the Paris office held meetings every six months to review the working of the conventions. Sir Alexander Russell is now in charge of anti-diphtheria measures in Scotland, and he mentioned that during the last six weeks approximately 250,000 persons had been immunized; the number aimed at is 800,000.

Hospital Beds in Glasgow

Sir Patrick Dollan, Lord Provost of Glasgow, presiding at the Court of Contributors of the Victoria Infirmary on February 19, suggested that an excessive number of beds had been reserved for air-raid casualties in Glasgow. He urged that the Department of Health should review the matter and take more into consideration the local knowledge of hospital governors and staffs. At the Victoria Hospital there were 300 beds so reserved, and the average waiting list at this hospital was above 600. He also drew attention to the large number of road accident victims, and suggested that the three city infirmaries—the Royal, the Western, and the Victoria—should combine in an inquiry into the subject, on the assumption that a large number of these casualties were avoidable. One matter for inquiry might be the fact that five times more males than females were injured; was it that women were more "safety-conscious" than men? It was reported that at the Victoria Infirmary there was a deficit on general maintenance account of £17,000. The cost of maintenance, owing to the rise in the price of commodities, showed an increase of nearly £12,500 over that for the previous year.

Central Midwives Board

At the last meeting of the Central Midwives Board for Scotland intimation was made of the appointment of the following persons to be members of the Board for a period of five years. The appointing body is named within parentheses.

Mr. Peter Taylor, Mrs. Frances A. W. B. Allan, Miss Mary McGhie, Miss Margaret Wilson Risk, and Miss Margaret Rachel Gouk (Department of Health for Scotland).

Mrs. Clarice M. M. Shaw (Association of County Councils for Scotland).

David Robertson, M.A., LL.B. (Convention of Royal Burghs).

Miss Isabella Cromarty Dewar (Queen's Institute of District Nursing, Scottish Branch).

A. S. M. Macgregor, M.D., F.R.F.P.S. (Society of Medical Officers of Health for Scotland).

Prof. R. W. Johnstone, M.D., F.R.C.S.Ed., F.R.C.O.G. (University Court of Edinburgh).

Prof. Margaret Fairlie, M.B., F.R.C.O.G. (University Court of St. Andrews).

Prof. James Hendry, M.B., F.R.F.P.S., F.R.C.O.G. (University Court of Glasgow).

Prof. Dugald Baird, M.D., F.R.C.O.G. (University Court of Aberdeen).

W. F. T. Haultain, M.B., F.R.C.S.Ed., F.R.C.O.G. (Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow, conjointly).

David Dale Logan, M.D., F.R.F.P.S., and William Leslie Cuthbert, M.B. (Scottish Committee of the British Medical Association).

Prof. Johnstone and Prof. Hendry were elected chairman and deputy chairman respectively for the ensuing year. Examiners were appointed and institutions were approved for the training of pupil midwives.

IRELAND

Medical Meetings in Belfast

A wartime innovation has been introduced in the collaboration of the Ulster Medical Society and the Northern Ireland Branch of the British Medical Association in a series of very successful meetings which are being held in the Whitla Medical Institute, Belfast, every fortnight. Members of the R.A.M.C. are invited, and there has been a large attendance at every meeting to hear papers on varying subjects and to take part in the discussions. The first of the series, under the presidency of Mr T. S. S. Holmes, was held on November 20, 1940, when Lieut.-Colonel L. B. Cole read a paper entitled "Diabetic Coma in a Series of Young Diabetics." He dealt with the causes of coma and its treatment, and mentioned some measures which might prove effective in its prevention. In a paper entitled "Peripheral Arterial Embolectomy" Major H. Agar recorded the operative details as well as actual cases, and explained that this condition, formerly thought hopeless, could now be tackled surgically with a reasonable hope of recovery.

The meeting on December 4 was preceded by the ceremony of the unveiling of the portrait of the late Sir Robert Johnstone—a gift from Lady Johnstone. Mr. Holmes paid eloquent tribute to Sir Robert's professional attainments and spoke warmly of his qualities as a man. Dr. Charlotte Warner then read a paper on "The Child, the Community, and the General Practitioner," in which she emphasized the importance of the doctor's taking a more active interest in the child's welfare from the post-natal period to the years of puberty. She also expressed the opinion that advice should be given by a doctor rather than by the child's relatives, and illustrated her contentions by quoting cases with which she had come into contact. Major B. W. Rycroft read a paper on "Some Recent Advances in Ophthalmology" and illustrated it with two films, one on the fitting of contact glasses and the other on corneal grafting. At the next meeting Lieut.-Colonel R. W. D. Turner, in a paper on "Sciatic Pain," outlined the defects in the present means of diagnosis and passed on to a classification of sciatic pain in its different forms. Each condition demanded specific treatment, and Colonel Turner dealt particularly with extradural injection for acute sciatic neuritis and local injection into the fibrositic muscles. Dr. B. R. Clarke read a paper entitled "Case-finding in Pulmonary Tuberculosis." He described the cineradiography method of discovery and illustrated his points with statistics and an excellent series of *x*-ray photographs showing various lesions. Then followed an animated discussion, in the course of which Mr. R. J. W. Withers spoke of his experience with sciatic scoliosis and showed slides illustrating the value of a plaster jacket. Three papers on "Non-penetrating Injuries caused by Blast" were contributed by officers of the R.A.M.C. Lieut.-Colonel R. Coyte classified blast injuries into two main categories—blast in air and in water. He divided these again into injuries caused by near, moderately near, and far-distant blast, and quoted cases illustrative of these types. Major W. C. Barbour described two cases of blast in water in which there had been a perforation of the ileum about eighteen inches from the caecum, and discussed the mechanism of the production of the condition. A paper by Major J. W. Osbourne was read by Major H. E. Bonnell in the absence of the former through illness. The physics of blast waves were dealt with, and quotations from Zuckerman's experiments showed the effects of blast on animals at certain distances. Post-mortem findings were related, together with a description of symptoms and treatment, in the cases of intracranial damage.

A discussion of the casualty services in Northern Ireland was the subject of an interesting meeting in which Prof. T. Flynn, Dr. F. M. B. Allen, and Dr. F. P. Montgomery were the principal speakers. Prof. Flynn, Chief Casualty Officer for Belfast, described the collection of casualties and the procedure to be followed in the event of a raid, emphasizing the importance of the "Report Centre." An account of the Emergency Medical Service was given by Dr. Allen, Hospital Officer to the Ministry of Public Security, in which he described the position of the various hospitals in Northern Ireland and the facilities for the treatment of wounded in the area of each hospital. He mentioned the mobile surgical teams, which could be sent to any part of the country, and emphasized his desire to see a store of plasma in every casualty-receiving hospital. Dr. Montgomery spoke of the Royal Victoria Hospital, Belfast, as a casualty-receiving hospital and discussed the various protective measures for the safety of the institution. He also dealt with the problems of staffing and the possibility of having to carry on the work of the hospital when water, gas, and electricity supplies were not available. During the discussion which followed, the D.D.M.S., Brigadier D. T. Richardson, offered his whole-hearted help to the civil authorities in the organization of the casualty services. At the sixth meeting of the series Dr. R. Thompson of Armagh read an instructive paper on the "Depressive Phase of Manic-depressive Insanity," quoting Kraepelin's classification of the disorder

and detailing the several degrees of the melancholia cases. He discussed the symptomatology of each type and described their treatment, emphasis being laid on prevention of suicide and on the necessity for rest in bed. Prof. J. H. Biggart then gave an address entitled "The Interrelationship of the Endocrine Glands" and showed a large number of slides of the various changes found in cases of overacting and underacting pituitary. He pointed out that the physiology of these glands was based on animal experimentation and was therefore fallacious, and that further human study was required. Through the courtesy of Colonel W. R. Ward, A.M.S., a meeting was held at the 24th (London) General Hospital, at which a large number of cases of clinical interest were shown.

Correspondence

Medicine in a Changing World

SIR,—The correspondence which has followed the publication of the lecture on "Trends in Nutrition" and your leading article on "Medicine in a Changing World" in the issue of January 18 indicates that at least some of the members of the Association think that the medical profession should make a contribution to planning for post-war reconstruction.

While there may be differences of opinion as to what part medicine should play in planning, there is general agreement that planning is necessary. It is now being realized that this war is the convulsive end of an epoch. When the fighting finishes there will be a new order of some kind. To avoid a breakdown of the economic and social system we must have a plan for the adjustment of the existing system to make possible orderly progress towards the new order. To this end the Government has already set up a new Planning Department, and a number of other influential groups are planning independently.

But what are they planning for? Between the last war and this one there was a great deal of economic planning on both a national and an international scale. The main schemes which came to fruition were those which restricted the production and distribution of commodities which people need. This setting up of barriers between the common people and the great wealth which science has made possible tends to perpetuate economic distress and poverty. This led to discontent and a feeling of frustration which the Dictators exploited to gain the allegiance of the common people, and especially of youth, to whom they promised a new and better economic system.

And now we start planning again. But this time, whatever ideas the planners may have, there is a strong and growing opinion that instead of piecemeal planning for sectional interest there should be comprehensive planning for the welfare of the whole population. In Government planning the first objective should be to provide the necessities of life for all the people governed. Mr. Churchill's reference to the fuller life of the common man, and Mr. Bevin's reference to relegating the miseries of poverty to the limbo of the past, as the main objective of post-war reconstruction, have given expression to this idea.

Now here is where medicine can make an invaluable contribution both to national and to international planning. It can define the requirements for physiological and psychological well-being, which are essential for a full life. By defining the first objective of planning they will have set it upon the right course.

In your leading article you point out the danger of the profession's being involved in politics. The profession would lose its influence if it allowed itself to become the battleground for conflicting political and economic theories. While members of the profession as citizens should be free to hold any political views they think right, the profession as a profession should be apart from, and above, politics. But it should be interested in the promotion of health, and planners should look to it for guidance on the kind of conditions under which the common man would be able to attain his fullest inherited capacity for health and physical fitness. A statement of these conditions based on facts, so far as they can be ascertained, would be a scientific, not a political, statement.

If the B.M.A. would undertake the task of laying down the standards needed for health and set them forth in what you, in your leading article, call a "medical charter," it would do much to lift all this planning out of the party political sphere. It would give the planners something definite to plan for, and enable them to deal with realities instead of with political and economic theories. As your correspondent Mr. Sayle Creer points out, the needs of man are absolute and unchanging and can be ascertained by investigation, whereas economic and political laws are alterable by man. Once the standards for human needs have been determined, the necessary political and economic adjustments can be made to provide for the needs. A statement of the needs would be a chart to planners. Once they had a clear idea of what was needing to be done they would tend to forget their conflicting theories and collaborate to devise ways and means of getting at the desired objective.

In the present crisis, when people of all shades of political opinion are co-operating in a spirit of good will to save freedom and build a better world, the B.M.A. can make an invaluable contribution to human welfare. It has the knowledge and the authority to state the first things that should be done. If the terms of the proposed "medical charter" were fulfilled—that is, if conditions were such that the whole population can attain physiological well-being—the worst evils of the past would be abolished. We would be well on the way to the new era of plenty. Indeed, we would be more than half-way home.

It is to be hoped that the B.M.A. will rise to the occasion and produce a charter which might well be of greater importance for humanity than many of the great historic political charters and declarations.—I am, etc.,

Aberdeen, Feb. 24. JOHN BOYD ORR.

*** Sir John Orr's letter, to which reference is made in a leading article at page 366, brings this correspondence to a close.—ED., *B.M.J.*

Effect of Peritoneal Irritation on Intestinal Activity

SIR,—I have read with pleasure and interest the paper by Mr. D. M. Douglas and Dr. F. C. Mann (February 15, p. 227). The subject of functional paralysis of the intestine was the theme of the Bradshaw Lecture I delivered in 1934, and I chose it "in the hope of inciting more workers in this country to enter a field of clinical and experimental research from which knowledge that will halve the risk and quarter the suffering that now attend abdominal operations is waiting to be garnered."

The problem is one which requires a welding of clinical and laboratory research, and no theory founded on experimental work can be acceptable unless it accords with and explains the clinical facts. An enormous number of experiments on dogs and other animals have been carried out, many of which to my mind miss the mark. For instance, a loop of gut or its afferent or efferent vessels are ligatured, and the investigator seeks to discover why the animal develops certain symptoms and dies. But surely the basic reason is the ligature!

Post-operative functional obstruction may be accompanied by peritoneal irritation, but the accompaniment is not constant, and, vice versa, peritoneal irritation frequently exists without any functional obstruction. The cases that most of all need investigation, and an explanation of which would throw a flood of light on the problem, are those in which functional obstruction occurs after operations not opening the peritoneal cavity, such as prostatectomy and nephrectomy, or sequent to states in which an operation plays no part, such as lobar pneumonia and severe injuries about the hip-joint.

The conclusion I reached in my lecture was that the motor and vasomotor disturbances in the intestine, fundamental to the derangement, are caused by an agent generated somewhere in the tissues that the operation, accident, or disease has injured, and that this tissue lies either in the peritoneal cavity or in close proximity to it. Such evidence as is available suggests that its production has some relation to partial circulatory interference in the tissue in which it is produced. Whether the agent, once produced, acts directly by blood or lymph conveyance or indirectly through the splanchnic nerves is not

clear, but the latter seems the most probable if only one manner of action exists. I deliberately employed the term "agent" in the same sense as the mathematician employs "x" to denote an unknown quantity, but if speculation may be indulged in I would say it is probably a substance, biochemical in nature, which antagonizes the mechanism which links the nerve-ending to the muscle.

I would hope that Mr. Douglas and Dr. Mann before they continue their valuable work would read my paper (if they have not already done so), because I think it would help them to determine the course that experimental work should take in order to reap the greatest advantage.—I am, etc.,

Feb. 23. VICTOR BONNEY.

Chemoprophylaxis by Proflavine

SIR,—In the valuable contribution made by Dr. Frank Hawking on the prevention of gas-gangrene infections by the local application of sulphonamide compounds, published in your issue of February 22, there is a short reference (p. 265) to comparative tests made with proflavine. Considerations of space doubtless prevented the full presentation of his results under this heading, but from what he does say we agree with your leading article on page 283 of the same issue, that the "acridine compounds still have a claim to consideration." Thus Dr. Hawking does not mention whether any of the animals died after proflavine prophylaxis: evidently some survived, because we learn that wounds reopened on the third day showed only small numbers of bacilli and "fairly healthy tissues." This seems to compare favourably with his sulphonamide series, in which he says that "smears from the wounds on the third day invariably demonstrated great numbers of Clostridia," while sloughs and necrotic tissue were present. We regret that he deprecated the use of the acridine compounds on the grounds of the mediocre results obtained in the last war. We have carefully read the reports published at that time and have generally found it impossible to establish which member or members of the acridine series had been used. In our experience both acriflavine and euflavine are highly damaging to the tissues, whereas proflavine sulphate and 2:7-diamino-acridine are practically harmless. We can well believe that a wound might not prosper after treatment with either of the two first-mentioned compounds.

During the past year proflavine sulphate has been used in this department in the prophylactic treatment of head wounds, including six cases of compound fracture or gunshot wound of the skull, with gratifying results. In five of these six cases solutions of 0.1% proflavine at *p*H 6.3 (made from Boots isoflav tablets) were used freely as irrigating lotions to the exposed brain and skull wounds after débridement had been carried out and before the wounds were closed by primary suture. In the sixth case multiple small penetrating wounds had been caused by the discharge of a shot-gun at close range and several of the pellets had entered the brain. As a thorough débridement was technically impossible the various puncture wounds were treated by a single irrigation with proflavine solution. Only one out of the six patients died, the remainder, including the case of shot-gun wounds, healing by first intention without any signs of wound infection or oedema of the brain. In the fatal case death occurred twelve hours after operation from shock due to multiple injuries to other parts of the body. Histological examination of the brain showed no damage in excess of the trauma inflicted.—We are, etc.,

Nuffield Department of Surgery, Oxford, Feb. 27. DOROTHY S. RUSSELL. MURRAY A. FALCONER.

SIR,—In a recent paper of mine on the prevention of gas-gangrene infections by the local application of sulphonamide compounds, a brief reference was made to some comparative tests undertaken with proflavine. I must apologize if a false impression has been given that I wished to cast doubt upon the use of this compound as a wound-antiseptic. In the few animals which were treated with 1% or 0.1% proflavine the results were approximately equal to those after treatment with sulphathiazole. However, no detailed comparison between proflavine and sulphathiazole was made, partly because this lay outside the intended scope of the investigation and partly because it was understood that sufficient clinical experience (which is the final arbiter) was now available to assess the merits and limitations of the use of proflavine. Dr. Dorothy Russell and Mr. Murray Falconer have kindly permitted me to see their letter describing the six cases treated with this compound. A comparison between a series of human wounds dressed with sulphonamides and a parallel series dressed with proflavine would certainly be most valuable. Such a study, however, would have to be made at a large centre where much material was available.—I am, etc.,

National Institute for Medical Research, London, N.W.3, March 3. F. HAWKING.

Local Application of Sulphonamides

SIR,—In view of the recent work on local sulphonamides, are we not justified in putting into immediate and wide-scale effect some of the known results? Would it not be reasonable for all wounds to be dusted with sulphanilamide powder (or, better still, sulphanilamide 2 parts and sulphathiazole 1 part) before the first-aid dressing is applied? To first-aid kits could be added a modified pepper-pot with a screw cap to cover the perforated end, filled with powder. It would be a matter of moments only for a first-aid man to unscrew the cap and sprinkle the powder on to the wound before applying the first dressing. He need not interfere with the wound and need not contaminate the top of the "pepper-pot" with his fingers.

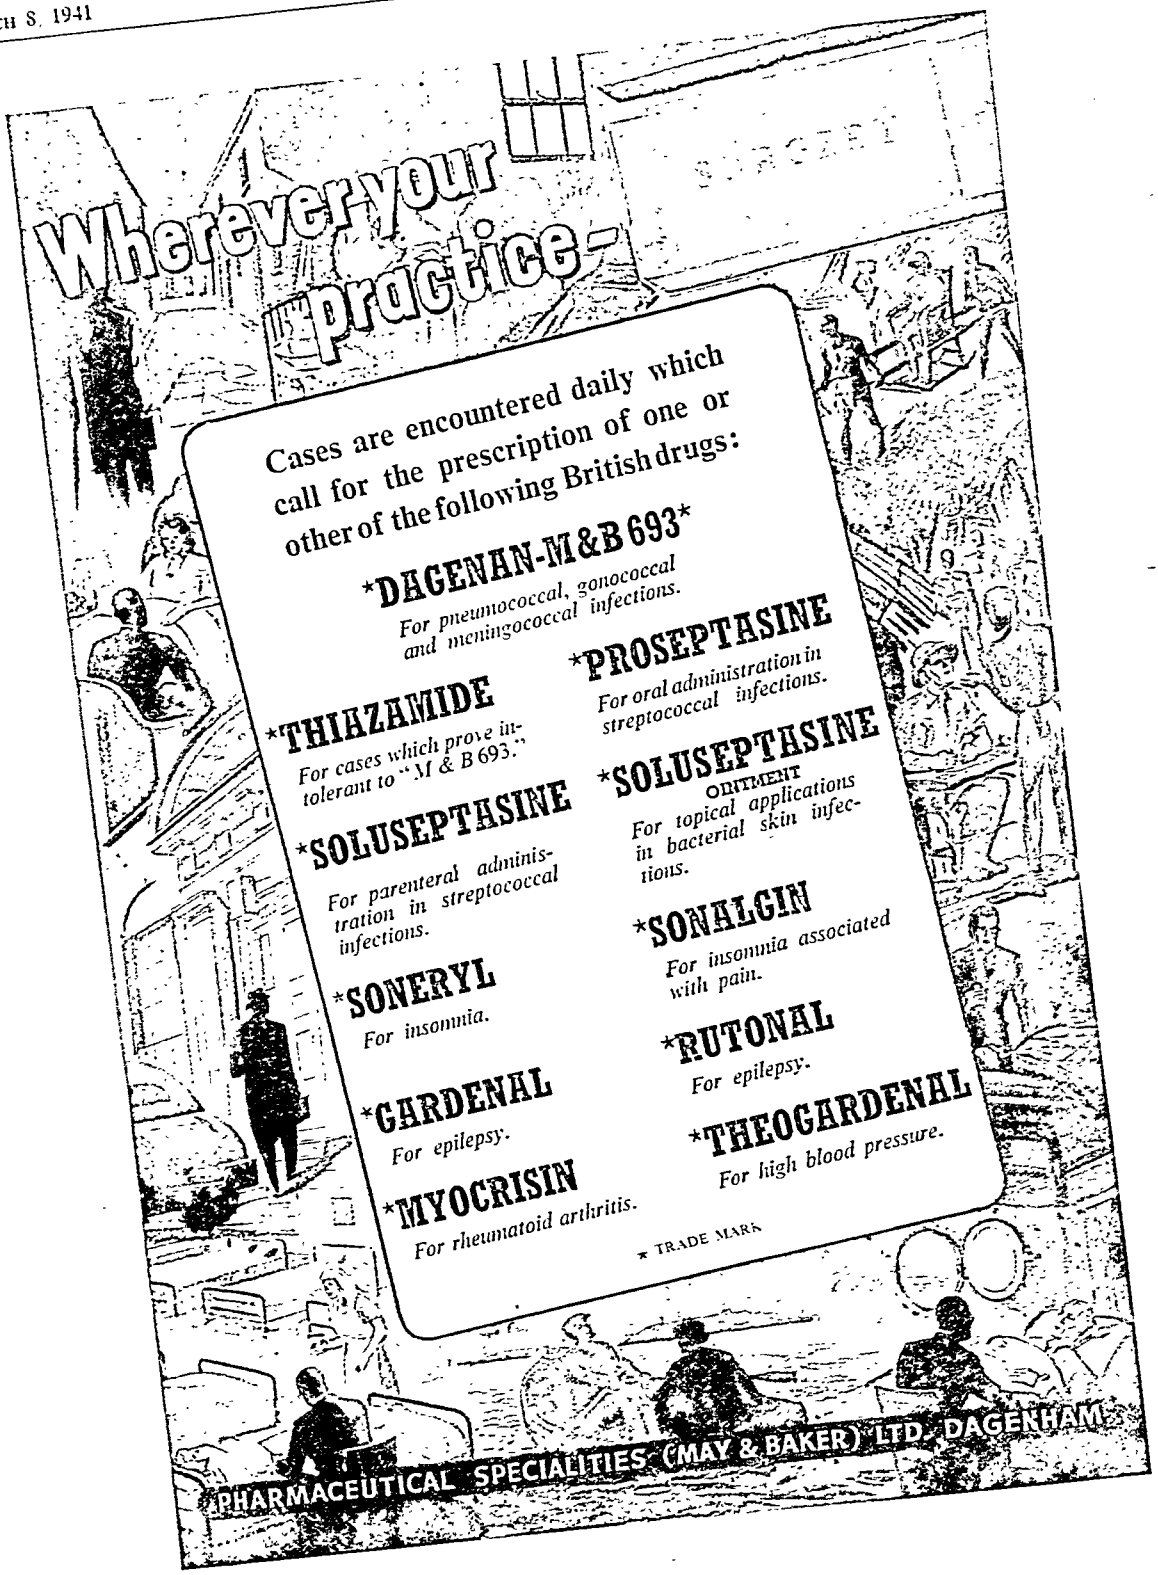
Dr. F. Hawking (February 22, p. 263) has shown that two hours' delay in applying sulphonamides locally produced fatal results in his animal experiments.

For those cases of wounds which after admission to hospital cannot immediately be taken to the theatre on account of shock or pressure of other cases, insufflation of the wounds with sulphanilamide and sulphathiazole powder as soon as possible appears to be indicated. Early in the period of resuscitation many wounds could have the fine nozzle of an insufflator gently inserted into the depth of the wound and a reasonable amount of powder blown in, without disturbing the patient or interfering with the treatment of shock. One could then leave each patient to take his proper turn in the theatre list, with some certainty that the growth of many virulent organisms would, at any rate, be inhibited.—I am, etc.,

Manor Hospital, Walsall, Feb. 22. E. S. CLAYTON, Medical Superintendent.

A.R.P. Casualties

SIR,—In some recent admissions shock seems to have been far greater than could be accounted for by the nature of the injuries. It appears that until last summer four blankets were considered to be the standard equipment for each stretcher in the ambulance. In some districts, however, two blankets were withdrawn during the summer months, and it appears that these have not been restored for winter service; neither have hot-water bottles been conspicuously in evidence. In some cases I saw the patients shivering with cold.



To facilitate quick exchange of blankets on arrival at hospital there should be a standard ruling for all districts and all authorities in this respect. Recent experience indicates that two blankets, however cunningly folded, are insufficient, notably in the case of a large patient, whose body surface loses a correspondingly greater quantity of heat.

It might make for speed and efficiency if local authorities were told to provide a thick felt or stuffed underpad, covered with spongeable material, just fitting and tied to each stretcher in the ambulance; when soiled it could be exchanged at the hospital, as is the case with the blankets. Some of the blankets in use, especially the cotton ones, are more weighty than warm.

Attention to these matters is evidently urgently required.—I am, etc.,

London, W.1, Feb. 24. G. H. COLT.

SIR,—May we submit the following comments on the article by Dr. Margaret Ball and Mr. George Quist. Our comments are based on a personal experience of some eighty air-raid casualties.

Wherever your practice—
Cases are encountered daily which call for the prescription of one or other of the following British drugs:
DAGENAN-M&B 693
For pneumococcal, gonococcal and meningococcal infections.
*THIAZAMIDE
For cases which prove intolerant to "M & B 693."
*PROSEPTASINE
For oral administration in streptococcal infections.
*SOLUSEPTASINE
For parenteral administration in streptococcal infections.
*SOLUSEPTASINE OINTMENT
For topical applications in bacterial skin infections.
*SONERYL
For insomnia.
*SONALGIN
For insomnia associated with pain.
*CARDENAL
For epilepsy.
*RUTONAL
For epilepsy.
*MYOCRISIN
For rheumatoid arthritis.
*THEOCARDENAL
For high blood pressure.

SURGICAL SERVICE
SALTAIR

These

ARE THE POSITIVE RESULTS OF THE ADOPTION OF

SALT'S SACRO-ILIAC BELT:

1. Firm, equable and continuous pressure is applied to the pelvic girdle — always with complete comfort.
2. The subluxated components of the articulation are thereby approximated.
3. The normal relationship of the sacral and iliac bones are restored.
4. Pain is quickly relieved, so that the patient can resume her normal avocations.
5. A beneficial effect is exerted on the tone of the abdominal viscera.

In addition to this Belt there are alternative Corset models available, having exactly the same effects and only differing in the matter of style. All these appliances are described and illustrated in Salt's Corset & Belt Book, which will be sent post free to any Doctor who lets us have a request for same. This Book contains Measure/Order forms which have been found distinctly time-saving for the busy Practitioner.

London Consulting Rooms:
"OAKLEY HOUSE,"
14-18, Bloomsbury Street, W.C.1.
Female Fitters in attendance Monday to Friday.
Orthopædic Mechanician Wednesdays only.
By Appointment.

Guarantee
"We guarantee to alter exchange or accept the return of any appliance without cost ordered by the Medical Profession, if not found Suitable within fourteen days from date of supply."
Salt and Son Ltd.

SALT & SON LTD · BIRMINGHAM 4

Our operative technique differed from Ball and Quist's only in the routine use of sulphapyridine powder as a dressing for the excised wound.

We have had no case of gas gangrene. None of the three cases of gas gangrene reported by Ball and Quist had received local sulphonamide treatment, which Hawking (February 22, p. 263) has shown experimentally to be more effective than systemic administration. This is also borne out by the series of cases reported by King (February 15, p. 231) and others.

Ball and Quist do not regard routine x-rays of the limbs as absolutely essential. We have found that in the absence of routine radiographs of the limbs the existence of complications which necessitate the removal of small foreign bodies may be overlooked, and that secondary operations undertaken at a time when infection has become established may then be required. We quote the following case as an example. A man aged 49 had a small penetrating wound in the right calf. This received routine operative treatment, but a subsequent radiograph showed a small bomb fragment lodged in a fracture of the fibula. This fragment required removal later owing to sepsis, and osteomyelitis is now established.

In our series the results of resuscitation treatment, including blood and plasma transfusion, were uniformly good, only one patient dying of shock after admission. It would be interesting to hear which, if either, of these two contrasting results has been the more general experience.—We are, etc.,

W. H. GRAHAM JESSOP.
ARNOLD S. ALDIS.

Cardiff, Feb. 24.

SIR,—The data given by Dr. Margaret Ball and Mr George Quist (February 22, p. 273) are useful and interesting, but there are some further details which many of us would like from a first-aid viewpoint.

How far away was the incident? Was it in a closed or an open space? Was there an awkward or long ambulance journey? Could blast have complicated the shock of these patients? Was any morphia given or other shock treatment attempted at the site of the incident? Was any fluid given by mouth? If so, what? Were the tourniquets complained of applied by trained first-aiders?

I might add that I have tried to crystallize "shock" to my first-aid pupils as "loss, more or less complete, of muscular and nervous tone." They can all grasp the difference in tone of their own muscle when fit and when exhausted.—I am, etc.,

W. F. BENSTED-SMITH.

Devon, Feb. 23.

Calcium Metabolism

SIR,—In the discussion on calcium metabolism in your columns one important point has not been brought out. I refer to the methods of estimation of calcium. The accurate determination of this element in biological material presents some difficulties, especially in the analysis of low-calcium diets. The analyst unaccustomed to this particular estimation may be unaware that the results he is producing are incorrect. Calcium balance experiments are not easy to carry out, as Dr. R. A. McCance remarks, and a carefully planned experiment is as easily ruined in the laboratory as in the ward.

It is possible that much of the conflict in the evidence that appears in medical literature has its origin in experimental or analytical errors which might be obvious if more details were reported.—I am, etc.,

A. B. ANDERSON.

Royal Infirmary, Glasgow, Feb. 25.

SIR,—Regarding Dr. R. A. McCance's article on calcium metabolism (February 22, p. 276), it is curious that what is, in a way, a mass experiment of administering calcium by inhalation has received so little attention. I refer to workers in lime dusts. Fisac (1909) reports that in Spain the workers in quicklime and plaster-of-Paris are immune to tuberculosis, despite the fact that they live in squalid dwellings and are underfed. Hamburger (*Journal*, January 8, 1916) states: "Labourers in limekilns do not get tuberculosis." In a dusty chalk industry in France M. Rénon reported an absence of tuberculosis among the workers, though they were very alcoholic.—I am, etc.,

W. J. BURNS SELKIRK.

Birmingham, Feb. 27.

Control of Scabies

SIR,—I quite agree with Dr. Allan Bigham (February 22, p. 294) that scabies might well be treated in gas *decontamination* stations. This procedure has been adopted in this borough for some weeks past and is working quite satisfactorily. I have notified the general practitioners that if they wish any of their patients suffering from scabies to be treated at the first-aid post centre they should notify me and the matter will be arranged. In this way a number of adults and children are constantly being cleansed, and both doctors and patients appreciate the facilities that have been provided.

I have had no experience with benzyl benzoate therapy, but if this method of treatment is more certain and effective than sulphur ointment the eradication of scabies would be helped by facilities being given for an increased supply of benzyl benzoate.—I am, etc.,

W. F. CORFIELD.
Medical Officer of Health.

Colchester, Feb. 24.

SIR,—I was much interested to read Dr. Allan Bigham's letter on scabies, and I readily approve his suggestions for stamping out the disease.

In general practice in this industrial area in the Midlands I have noted with growing concern the steadily increasing incidence of scabies, and I feel that unless more intensive measures are adopted for its control it may seriously affect the output of employees engaged in work of national importance. I am repeatedly confronted with the young panel patient who is keen to be treated and rid of the pest, thus permitting him to perform his work satisfactorily and enjoy proper rest, but am further informed that other members of the family have the same disease, and for reasons of financial need (not enjoying the benefits of free treatment) or perhaps sheer apathy remain untreated, and so form a source of infection to an ever-increasing circle of contacts.

It would appear, therefore, that stricter control is required, and I venture to suggest that (1) scabies should be a notifiable disease, and (2) local authorities should provide facilities for free treatment as in the case of other infectious diseases.—I am, etc.,

J. BORRIE HARRIS.

Tipton, Staffs, Feb 23

Chicken-pox with Bell's Palsy

SIR,—In your issue of February 15 (pp. 234 and 236) were two most interesting articles on "Paresis following Herpes Zoster" (Drs. A. Barham Carter and John B. W. Dunlop) and "Bell's Palsy and Herpes Zoster" (Major John D. Spillane), which brought to my mind a case of chicken-pox with Bell's palsy which occurred in my practice about ten years ago. The patient was a healthy girl of 11 years who had the severest attack of chicken-pox I have ever seen; the rash was very widespread, particularly on the face, and constitutional disturbance was severe. On the fifth day of the illness, while she was still febrile, there appeared a complete peripheral facial palsy. The well-known association between chicken-pox and herpes zoster supplied an explanation, though it had not been my experience (then) to see a case of motor-nerve involvement in a case of the latter. The paresis cleared up completely in about six weeks.

Since this experience I have always felt that the typical Bell's palsy must be due to a virus akin to that of herpes zoster, as it surely would be a much commoner condition if chill were the only causative factor, and this hypothesis, I note with interest, is supported by Major Spillane in his article.—I am, etc.,

A. R. C. DOORLY.

Surbiton, Feb. 25

Muscular Lesions in Somatic Pain

SIR,—The observations of Mr. Martin Button (August 10, 1940, p. 183) upon muscular rheumatism, and of those who took part in the subsequent correspondence, have been abundantly confirmed by my experiences in general practice during the past two and a half years. Since the publication of the earliest work of Sir Thomas Lewis and Mr. J. H. Kellgren (*Journal*, February 12, 1938, pp. 321 and 325) I have been ready to give this method a trial in all cases of somatic pain, and many

apparently of visceral origin. The general practitioner is very conveniently situated with a view to carrying out important researches upon somatic pain, for he constantly sees large numbers of these cases, and he is provided with an instrument of great scientific precision in local anaesthesia.

So regularly does a persistent search reveal a muscular lesion that I have come to regard this as the cause of any case of obscure pain until proved otherwise. Intramuscular nodules are found in many cases of headache, in a number of cases of painful shoulder, and in the majority with "brachial neuritis." They occur in all cases of pleurodynia, and in many cases which resemble angina pectoris. Muscular lesions can simulate the symptoms in every kind of visceral disease, and they can usually be discovered in lumbago, "sacro-iliac disease," and sciatica. They can be found in adjacent muscles in association with painful knees, and they occur with almost regular frequency in painful feet. Their frequency is unbelievable to one who has not become familiar with the idea of their existence. They have certain sites of election where they will be found with almost monotonous regularity. These situations are tender in the normal subject, and are the site of soreness when an untrained muscle becomes "stiff" from fatigue. These situations are:

Symptom	*Situation*
Headache	Nuchal muscles at about the level of the sixth cervical vertebra. (Cyriax, *British Medical Journal*, 1938, 1, 1367.)
Shoulder pain	Anterior border of trapezius in mid-clavicular line.
Pain in forearm and hand	Extensor muscles just below external epicondyle.
Pleurodynia	Edge of erector spinae.
Lumbago and "sacro-iliac strain"	Edge of erector spinae; more commonly in fibres of origin of gluteus maximus, just outside posterior superior spine. (This spot was described by Souttar in 1923.)
Abdominal visceral disease	Same as for lumbar pain.
Sciatica	Lower half of gluteal mass.
Painful knees	Region of adductor tubercle: upper ends of calf muscles. (Kellgren, *Clinical Science*, December, 1939.)
Painful feet	Plantar surface of first metatarsal; deep situation in sole near scaphoid.

The rectus abdominis should be carefully examined when abdominal discomfort is prominent. Nodules may occur in any other muscles.

The reality of this condition is gradually coming to gain recognition, as shown by the correspondence in your columns, and by the recent observations of Copeman and Burt (*Post-graduate Medical Journal*, September, 1940) and of Harman and Young (*Lancet*, June 22, 1940). J. B. Mennell has for years been writing on painful deposits in muscles, to which, he says, pain can often be solely attributed. The conception of neuritis should now be allowed to lapse into oblivion. In most (probably all) cases pain which shoots down a limb is not due to a nervous but to a muscular lesion. It is probable also that the orthodox views of many other common ailments will come to be modified in the light of these researches.

Copeman and Burt, among others, complain that their results are inconsistent; that they cannot predict which cases will be cured and in which the pain will recur. This also was my experience in the earlier stages of my observations, and indeed often enough at present. Many failures were due to my inability to distinguish between the referred tenderness and the tenderness of the lesion itself. The referred pain and tenderness tend to be located in the region of joints, and bony points beneath the skin may be acutely tender. It is disastrous to inject these points, though some immediate improvement will follow. The true lesion should be sought in adjacent muscle. Similarly, tendons, periosteum, and joint capsules should not be infiltrated; their tenderness will be found to vanish as if by magic when the true lesion is anaesthetized.

The discovery by Kellgren that a localized lesion can cause widely distributed referred pain and tenderness has opened up a large new field in which symptoms encountered every day attain a new significance. We are thus provided with the key to the understanding of many rheumatic manifestations, which are proved to have a common origin. I am reminded of the statement of Pennington (*British Journal of Rheumatism*, 1939, p. 3) that fibrositis, lumbago, sciatica, and neuritis are all local names for a probably identical process.

The researches I have mentioned will in the long run bring about an entirely new conception of the origin of pain. Hitherto we have been obsessed with nerves; pain is said to be due always to pressure on nerves. The knowledge that widespread tenderness will disappear on anaesthetization of a single painful spot should lead us to discard the views accepted at present, and to consult the work of Lewis upon nocifensor nerves (*British Medical Journal*, 1937, **1**, 431 and 491). An area of injury to tissue becomes surrounded by a spreading zone of hyperalgesia. This is brought about by a reflex through the nocifensor nervous system. Lewis likens the appearance of hyperalgesia to a process of secretion; injury to the tissues causes a nervous reflex by means of which a substance is liberated from the cells which lowers the threshold of pain nerve-endings. Similarly with a painful muscular lesion; its presence causes a continued stimulation of the nocifensor network immediately surrounding the lesion, and sometimes in distant areas. Further researches upon this network will no doubt demonstrate the linking up of the various somatic tissues and viscera in a unity whose closeness has not yet been generally suspected.—I am, etc.,

Bunbury, Western Australia, Dec. 3, 1940. MICHAEL KELLY.

Malignant Measles

SIR,—In view of the fact that "black" or malignant measles is of such rarity that a man of the late Claude Ker's wide experience could write that he had never seen an instance, the following case may be worth putting on record.

A child aged 9 months was brought to my surgery at 2.30 p.m., having vomited about half an hour previously. It was pale, with a temperature of 100.4° F. and a slightly increased respiration rate but no other physical signs, and the skin showed no suggestion of a rash. I was, however, impressed by the apathy of the child, indicating a degree of illness which the mother clearly did not appreciate, for I had to insist firmly that the child must be taken home at once and put to bed.

I was called to see it again at 2 a.m. the following morning. I found it *in extremis*; respirations rapid and shallow, lips cyanosed, and swallowing reflex absent. Its face, trunk, and limbs were covered with a measles rash which was deep purple in colour. Some of the spots had petechial centres and there were scattered purpuric areas up to half an inch in diameter. The child died within an hour and just over twelve hours after being first seen. The mother insists that until the onset of vomiting "there was nothing wrong with her."

The fulminating character of the illness, the nature of the rash, and the fact that an epidemic of measles was in progress in the town left little doubt as to the diagnosis. It has been stated that the disease should be differentiated from small-pox. In this instance the rash bore no resemblance to that of variola, of which I have had the opportunity of seeing several examples, and the child had been vaccinated.—I am, etc.,

Tiverton, Devon, Feb. 13. AUDREY Z. BAKER.

Intramuscular Quinine for Malaria

SIR,—Medical officers who have come to this country in the last few years have been imbued with the idea that intramuscular injections of quinine are fraught with danger. The quickest and most efficient and comfortable method of treating malaria is thereby denied to many patients. The danger of abscess formation is negligible if the precaution is taken to empty the needle of quinine by a shot of air from the syringe before it is withdrawn. If this is not done a track of quinine will be left when the needle is withdrawn. The area of injection should, of course, be massaged well.

In Kano practically everyone is infected with malaria during the rains. Three daily intramuscular injections of quinine grains 5 are found to cure the acute symptoms of malaria in all but the most exceptional cases. Quinine is afterwards given by the mouth in small doses. This is the routine in this native hospital of 300 beds, partly on account of its cheapness. The injection solution is made up in the dispensary, 5 grains of quinine bihydrochloride to 1 c.cm. of

water. The needles are regularly sharpened, and the injection, if given into the gluteus medius, is usually painless. The patient lies on his side and his uppermost leg is fully flexed. The upper border of the gluteus maximus is usually seen and the injection made at that level. This is about 2½ to 3 inches below and behind the anterior superior iliac spine.

I have never seen abortion caused by an injection of quinine even in those in whom a dose of 5 grains of quinine by the mouth causes pain in the uterus and bleeding.

Intravenous quinine should be reserved for cases of cerebral malaria. Europeans have an attack of syncope and sometimes a feeling of impending death just after the intravenous injection which can be most unpleasant. Africans do not suffer in this way, but owing to its rapid excretion it is not so efficacious as the intramuscular route.

Europeans in Nigeria who take prophylactic quinine while not having any temperature, often suffer from general lassitude, a heavy head, and occasional headaches. One injection of quinine is usually found sufficient to remove these and other malaria symptoms. Personally I submit to an intramuscular injection of quinine rather than suffer the unpleasant effects of large doses of quinine by the mouth.

Atebrin (quinacrine), while being very valuable in certain cases, particularly blackwater fever, does not suit all patients, and the relapse rate appears to be high.—I am, etc.,

Kano, Nigeria, Dec. 12. R. N. HALL.

Cyclical Mucosal Ulceration

SIR,—I was interested to read the article on cyclical mucosal ulceration by Dr. M. H. Pappworth (February 22, p. 271). It would be interesting to know whether an eosinophil count was made, and, if so, whether it was more than normal. One asks this question as so many conditions which occur in cycles in some patients have an allergic origin.—I am, etc.,

Liverpool, Feb. 24. J. BERNSTEIN.

Shelter Policy

SIR,—It is stated that 1,502 deaths resulted in January, 1941, from enemy air raids, and these will continue steadily if things remain as they are. Is the B.M.A. and are doctors generally, whose objectives are the preservation of life and health, satisfied that all is being done, as far as can be, to lessen this holocaust of our courageous fellow countrymen and women? If not, our primary duty is to make a formidable demand at once to the Government and to the Minister of Home Security to take all steps, as far as is humanly possible, to prevent this wounding and suffering in our home front line. Who of us will volunteer to do so?

In support (1) I refer to the *Journal* of February 15 (p. 250), which records a conference of the Association of Architects, Surveyors, and Technical Assistants, of the National A.R.P. Co-ordinating Committee, of various local authorities, and of doctors, which urged that a higher standard of protection against high explosives and a better shelter policy be introduced (without further departmental delays). Dr. Joan McMichael advocated, from a medical and safety aspect, the maximum degree of safety with a minimum of risk of disease, as is afforded by "two-stage" shelters (Haldane), because they could be strengthened so as to render them proof against medium (and even higher) calibre bombs. It is true that the Regional Commissioner for London, in charge of the shelter "problem," advocates the use of Anderson shelters, and Lord Horder believes in "domestic" shelters, but this Governmental viewpoint of "dispersal" is certainly not shared by all experts and is not in accordance with recent tragic experiences.

Again, (2) recognizing the vulnerability and repeated bombings of London and provincial hospitals, with losses of patients', nurses', and doctors' lives, bomb-proof hospitals should be provided for the (comparatively small) number of casualties and sick persons who cannot be moved out of the danger zone. For those casualties that can be moved suitable ferroconcrete buildings should be requisitioned along wide and strategic roads and their basements adapted as comparatively safe clearing stations, other patients being removed outside the danger zone (Socialist Medical Association leaflet, 33, Murray Road, Northwood, Middlesex). Many of the flimsy structures that have been and are being provided as shelters are potential death-traps.

These two gaps (1 and 2) in our home defences are a direct help to Hitler, and are comparable to the disastrous military events which led up to Dunkirk. How long will those of the medical profession, who mean to win this war, allow this "slaughter of the innocents" to continue without a collective challenge?—I am, etc.,

Woking, Feb. 24. F. G. BUSHNELL, M.D., Major R.A.M.C., T.F. (retired).

Supplementing the Dietary

SIR,—In the last war many doctors had notices in their surgeries exhorting their patients to "Eat less bread," and it seems to me that the time is now ripe for other notices referring to the present food situation.

Possibly "Eat more potatoes and less bread," "Carrots are *good for you*," and suchlike might be useful, but the outstanding requirement at the moment is some instruction about supplementing the foods which are in short supply—the fats and the proteins. Eggs might be recommended for their fat content, but unfortunately they go in with the scarcer proteins, meat, cheese, and fish. Milk also is not so plentiful that it can be used largely in additional amounts. Some recommendation should be made of the next best foods for their protein content—peas, beans, lentils, and oatmeal. A soup made of the pulses would be excellent, but the need that most folk feel is for a recipe for a pea or lentil soup which is palatable without the unobtainable ham bone in it. The vegetarians have been making it for years, and if the Ministry or the B.M.A. could produce posters containing practical advice in plain language, not in the highbrow sentences which sometimes adorn the hoardings of one or another of the Ministries, there is little doubt that doctors would put them up in their waiting-rooms. The patients might or might not be impressed by a blessing from the medical profession, but they would in any case have to sit and stare at the poster for a certain amount of time, and some of it would sink in.

It might be considered advisable to refer to the "Scottish ploughman's diet" recently mentioned in the *Journal* (January 11, p. 63); but the motive should be to point out that there is plenty of food of all necessary kinds if only a little trouble is taken. A short note might be added about use of vitamins in (if necessary) capsule form, one a day. May we hope for some action?—I am, etc.,

Leigh, Lancs., Feb. 24. JOSEPH JONES, M.D.

Medical Planning Commission

SIR,—As one of the younger members of the profession I should like to add my opinion of the B.M.A. Planning Commission and the future of medicine. I think that the chief reason why the Commission has met with so much criticism is the secrecy with which it was appointed without authority from the profession as a whole. For many reasons the Commission is not representative and does not command the support of a large body of the profession. It would seem, furthermore, from the Prime Minister's statement in the House of Commons, that the Government is not going to put much weight on the findings of the Commission. It seems to me, therefore, that the Commission is going to waste its time, and that the whole Commission, as appointed by the B.M.A., should be dropped.

I do feel, however, that the B.M.A. has done the right thing in taking the lead and suggesting that now is the time to plan for the future. No man can say how long the war will last, and it would be wrong to wait for the end of the war before beginning what will necessarily be lengthy deliberations on the future of medicine. I suggest, therefore, that the Government be strongly urged to appoint a small but representative Royal Commission, representative of every branch of the profession—of general practice in country, town, and colliery, of consulting medicine, research, teaching and public services, and especially of young and old, male and female.

Before it can hope to plan for the future the Commission must find out what is wrong with the medicine of the present. A profitable approach to the problem would be a questionary sent out to every British member of the profession, whether

at home or in the Forces, to ask (1) what from his experience he considers to be wrong with the present medical service of the country; (2) what suggestions he has to improve matters. The inclusion of the Forces in the questionary answers the criticism that this is the wrong time to have a Commission because so many are serving over-seas. A questionary would allow everyone to play his part in planning for the future. From the result of this investigation a constructive scheme for the future could be elaborated.

When one considers some of the faults of the present system some of the requirements of such a service immediately spring to one's mind:

1. The pooling of hospital beds. The present system, in which the voluntary hospital has a waiting list of anything up to five years while the municipal hospital in the same city has none, is manifestly absurd. Furthermore, in many teaching centres there is a shortage of clinical material for teaching in the voluntary hospital, with consequent overcrowding by students, whereas there is an abundance of material in the municipal hospital to which the students are not allowed access. I believe that the Nuffield Provincial Hospitals Trust is at present concerning itself with some of these problems.

2. A fairer scheme for admission to hospital. Selection of cases for admission from the waiting list should be governed by the urgency of the case and not by the payment of a consultation fee to a member of the hospital staff. In one hospital I know a patient with an inguinal hernia will wait two years for admission as an "ordinary case" and not more than a week if he has paid his three guineas.

3. Better pay for some house officers, for all research workers, registrars, and members of the nursing profession. It is absurd that some house officers and nurses, with all their responsibility for the lives of their patients, should be paid less than the maids, whose responsibility is to scrub the floor or tend the potato peeler. There must be many good young men who are deterred from attempting to climb up the tree to the honorary staff for fear of falling by the wayside through financial difficulty, especially when they are well up the tree and in the perilous stage without support when they first become junior members of the honorary staff.

4. The more even distribution of work in general practice. There is no valid reason why the general practitioner in a wealthy practice should earn much more money than a man doing three times more work in a depressed area.

5. Improvement of the standard of medicine. There should be compulsory "internship" for at least six months after qualification before going into practice, and facilities for all practitioners to keep up to date, with compulsory attendance at refresher courses at frequent intervals.

6. A solution of the financial difficulties which trouble the middle-class patient and the poor non-panel patient in outlying parts of the country in obtaining treatment. Only a few weeks ago I inquired my way at a farm so remote that the nearest doctor's fee was £1 per visit.

7. Better facilities for laboratory investigations at a reasonable cost, especially in country districts.

8. Better system of promotion. Promotion in any of the branches of the service should depend on ability, experience, and the degree of responsibility attached to the post, rather than on graft, nepotism, or merely on age or duration of service.

I feel that a full-time State Medical Service is the only one which can fulfil these and many other requirements. I do not for a moment hold with the argument advanced, especially by some senior physicians, that such a service would abolish initiative, individuality, or ambition. With the system of promotion mentioned the reverse would be the case. Space will not permit me to give my ideas about the financing of such a scheme, but I do not think that it presents great difficulties. Now is the time, when the future of medicine is in the melting pot, to think and plan for the future. It will be the profession's fault if the new State service after the war is a bad one, with the present evils unremedied.—I am, etc.,

Oxford, Feb. 24. RONALD S. ILLINGWORTH.

SIR,—In his letter (February 22, p. 295) Dr. C. E. S. Flemming asks: "Are we not giving too much importance to proportionate representation?" My answer is "No," if the object is to secure the full confidence of all sections. He then suggests that the function of the Commission is merely to take evidence and act as judge and jury. If this is in the nature of a trial, then under British usage the jury must be composed of one's peers, and 26,000 out of 36,000 doctors in Great Britain are general practitioners. He goes on to state: "What we want is men of understanding." Quite so—men understanding the difficulties and needs of general practice. We don't want "the opportunity of discussing the proposals" later on, but of taking a major part in formulating the proposals, so far as they affect general practice—and while writing this I am not forgetting that other questions of great importance, not peculiar to general practice, must also be considered. Dr. Flemming himself recognizes that the difficulties and needs of general practice must form a very important part of the Commission's work, yet he seems content to allow them to rest in the hands of a preponderant majority of consultants and public health officials, few of whom can have felt the pinch and the need for remedy. Take, for instance, his demand for beds in hospitals. Is he satisfied to leave a decision on this question in the hands of a majority whose life-work must incline them to the belief that no such step is necessary or desirable?

With the rest of Dr. Flemming's letter I am in complete agreement, but I prefer that the decisions on the questions he raises should be made by men who know the difficulties and needs personally, and not only by hearsay.—I am, etc.,

Ashover, Feb. 24. H. W. POOLER.

Dyspepsia in the Army

SIR,—In the *Journal* of March 1 Major Spillane criticizes the findings of our interim report on dyspepsia in the Army, especially our statistics relating to the high incidence of organic disease. Major Spillane will find a detailed answer to this criticism in our letter to the *Lancet* of February 8 in reply to Prof. Hartfall. There are, however, certain points which we should like to stress.

First, our investigation was primarily concerned with troops invalided home from the B.E.F. in the early days of the war. Secondly, we found a great tendency in the Army hospitals to label dyspeptic cases as functional ones, even, at times, in the face of most conclusive evidence to the contrary. Thirdly, we certainly agree that the dyspepsia problem at the present time may well be very different from that in the early days of the war. Finally, we must put forward a plea for the most careful diagnosis of the individual dyspeptic; and in the difficult or obscure case for a diagnosis based on a summation of all the evidence. Dyspepsia due to organic conditions such as ulceration may render a man totally unfit to be a soldier. Functional dyspepsia may or may not render a man unfit for service, but this diagnosis can only be scientifically and practically justified when organic disease has been first excluded by every possible means.

Major Spillane criticizes our statement that "among those investigated there was little evidence of minor dyspepsia." This statement did not appear in our original report to the Royal College of Physicians of London. It was inserted in our published report after discussion with the Army authorities and at their request. We could not, however, possibly object to its inclusion as a positive statement of fact, as it was in entire agreement with our experience in investigating B.E.F. and local sick in the early stages of the war. Whether or not such a statement could still be made of the dyspepsia problem is entirely outside the scope of our inquiry.

On the basis of our experience we are satisfied that the most careful investigation of the dyspepsia patient can be justified on the grounds of Army efficiency, public expenditure, and the health of the community.—We are, etc.,

REGINALD T. PAYNE.
London, March 3. CHARLES NEWMAN.

The forty-ninth semi-annual list (May 1 to November 1, 1940) of the publications of the staff of the Rockefeller Institute for Medical Research has been received. Copies of these lists will be posted regularly to those who send requests to the Publication Office, Rockefeller Institute for Medical Research, York Avenue and 66th Street, New York, N.Y.

Obituary

SIR FREDERICK BANTING, K.B.E., M.C., F.R.S.

LL.D., D.Sc., F.R.C.P., F.R.C.S.

As briefly announced in last week's issue, Sir Frederick Banting lost his life in an aeroplane accident in Newfoundland while on a mission concerned with research into medical aspects of flying.

Frederick Grant Banting was born on his father's farm at Alliston, Ontario, on November 4, 1891, and from Victoria College, Toronto, went to study medicine at the University of Toronto, qualifying in 1916. While serving in France with the Canadian Expeditionary Force he was severely wounded in one arm at Cambrai and invalided to England, and was awarded the Military Cross for his gallantry. In England he took the M.R.C.S. and L.R.C.P. diplomas, and returned to Canada in 1919 to become resident surgeon at the Hospital for Sick Children, Toronto. He then for two years combined practice at Toronto, Canada, with the work of a part-time assistant in physiology at the Western Hospital. On May 16, 1921, he began research on the internal secretion of the pancreas at Toronto, and was appointed lecturer in pharmacology at the University; it was the turning point of his career, for these were the experiments in collaboration with the late Prof. J. J. R. Macleod and Dr. C. H. Best which led to the discovery of insulin. The first inkling given to this country that Banting and Best were on the eve of an epoch-making pronouncement was an annotation in the *British Medical Journal* of July 22, 1922, headed "The Control of Glycosuria by the Islets of Langerhans," which referred to a preliminary paper published early that year in the *Journal of Laboratory and Clinical Medicine*. In these columns on November 4, 1922, J. J. R. Macleod gave to the British medical profession a summary of the work carried out during the past two years in the Toronto Medical School. His paper, entitled "Insulin and Diabetes: A General Statement of the Physiological and Therapeutic Effects of Insulin," was written at the invitation of the Editor, Dawson Williams, who had close contacts with medical science in Canada and had quickly recognized the great importance of this work at Toronto. Thenceforward Banting's name was a household word, and honour after honour came to him. He was awarded the Starr gold medal for the D.Sc. of Toronto in 1922, and in the following year was made Professor of Medical Research there; soon afterwards he received jointly with Macleod the Nobel prize for medicine, and was granted an annuity by the Canadian Government so that he might pursue his researches. He received in turn the Scott medal and the Favelle medal and Fellowship of the Royal Society of Canada, the Cameron prize of the University of Edinburgh, and the gold medal of the Apothecaries Society of London. He was an honorary doctor of a number of universities, the Royal College of Surgeons of England made him an honorary Fellow in 1930, he was elected a Fellow of the Royal Society in 1935, and the Royal College of Physicians of London made him a Fellow under By-law XXXIX (*b*) in 1936. He was created K.B.E. in 1934.

In the early months of the present war Sir Frederick Banting was in England attached to the Canadian Forces, with a view to special research in the Canadian Hospital here, but he returned to Canada to undertake investigations into the medical aspects of aeronautics as a member of the Technical and Scientific Development Committee set up at Ottawa. The Canadian Prime Minister told the House of Commons at Ottawa that Sir Frederick at the time of the aeroplane crash was proceeding to Britain on a mission of high national and scientific importance.

SIR HENRY DALE, P.R.S., writes:

It is sad to think that Banting has gone from us in what should have been still his scientific prime, though the dramatic end is not without its fitness to a career of research which had an unusual tinge of romance. The death of Keith Lucas in a flying accident in 1916 comes to mind, but with a suggestion of contrast more than of analogy. Lucas, at the age of 37, by work of increasing depth and brilliance over a decade, had given new form and substance to a whole range of fundamental physiology; to those who knew, he was already a master, but to the world at large his work meant nothing. Banting, who has died in his fiftieth year, was already a world celebrity in his earliest thirties. Rightly, as I think, the world gave him the biggest share of the credit for a great discovery, which brought about what is still the most dramatically sudden change in the aspect of a disease within living memory. Banting, however, had but little preparation for such an achievement, and his direct share in its development was relatively brief.

The year 1915 had found him still a medical student, and he served in France as a combatant, being wounded so severely as nearly to lose an arm, before he completed his qualification. By 1921, when the vision came to him, he seemed to be settled in medical practice in London, Ontario, with only a spare-time contact with the Department of Physiology there. The idea which had set his imagination aflame was not, in fact, a completely new one. Even its basal assumption that the action of trypsin had been responsible for frustrating earlier attempts to extract the anti-diabetic hormone from the pancreas has not survived the progress of knowledge; but this progress itself became possible only as a result of Banting's enterprise and determination. Carbohydrate physiology, in the thirty years following Minkowski's fundamental discovery, had left a trail strewn with the wreckage of attempts, many by workers of ripe experience, to extract the supposed hormone from the pancreas; and this was the problem which Banting, with no previous experience at all, was eager to tackle anew. When Macleod was asked to give him room for the attempt in the Toronto laboratory it would be natural for him to warn Banting, as he is said to have done, that this dismal history left little hope of success. It is more pertinent, I think, to remember that Macleod did, in any case, give Banting the chance of a trial, and, more important still, that he advised him to accept collaboration with a younger man, Charles Best, recently schooled under Macleod in methods of determining blood sugar and analysing respiratory gases. So these two young men, the one a surgeon with an insistent idea, the other still a student, but bringing essential technique to the joint equipment, embarked bravely on an enterprise which, through a Canadian summer, was to make demands on all their reserves of determination, conviction, and personal devotion. By dint of all these they succeeded in a few months in demonstrating directly that the hormone insulin had real existence, and that it could

be extracted in relatively permanent form, under appropriate conditions.

This was the first essential step. When once the possibility of extracting insulin had been established, other workers, first in the Toronto laboratories, led and organized by Macleod, and soon in many laboratories in many countries, contributed to the knowledge of its properties and to the discovery of methods for its purification. Such studies led eventually, and with a rapidity which would have seemed incredible when its existence was first demonstrated, and which still seems astonishing in retrospect, to the crystallization of pure insulin as a metallic salt. With all this further development, however, Banting had little concern. As soon as its partial purification had made clinical trials possible, he had centred his interest on the practical application of insulin in the treatment of diabetes; his Nobel Lecture in 1925 reviewed the clinical results obtained with it to that date. It was rather noteworthy, indeed, how soon he seemed ready to leave to others the further investigation of the properties of insulin and the mode of its action, and to direct his own researches to other objectives. It may be suspected that more than one influence was concerned in this decision. Banting would certainly be aware that such further developments required a fundamental equipment, especially on the chemical side, which he had had no chance of acquiring. He had shown, thus early in life, what he could do by natural insight in alliance with an iron determination, and without any normal apprenticeship in research. The best reward, from his point of view, would probably have been an opportunity to make good such defects of equipment by some years of quiet and disciplined study in the world's most productive centres of research, and then to return to researches chosen for himself in the light of the wider experience. Conditions, in any case, conspired to make such an arrangement difficult, or impossible. No other medical discovery in living memory has so caught the public interest as the discovery of insulin; and Banting, in particular, soon found himself, to his embarrassment, a mark for popular enthusiasm and excited expectation, in Canada first, and later in the world at large. Money was freely forthcoming, and it would have been difficult for those in authority to avoid founding a Banting Institute for Medical Research, with a Research Chair for himself as its director, or for Banting to refuse such a flattering opportunity. The whole atmosphere of haste and exaltation, however, could not fail to be detrimental. In spite of all pleas for patience and caution from those who were soberly concerned for Banting's future and for his further value to medical research, he had become a public figure; everything concerning him was "news," and the world at large had been taught what to expect. Every few months a new rumour was set afloat in the popular press, attributing some fresh discovery to Banting. I remember being asked myself, over the telephone, whether it was likely that he had discovered a cure for metabolism. His comings and goings were chronicled like those of any film-star.

Even a research worker of long experience and established repute would have found himself inhibited by such an atmosphere. When half the world is agape for a miracle it takes unusual courage to offer it the results of some sound and necessary but unexciting piece of spadework. The matter for surprise is, not that Banting should have seemed for a time to be somewhat embarrassed, but that he should, in the end, have been so little deflected from the proper use of the opportunity which had been given to him. For a few years, indeed, he seemed to feel a constraint towards problems of the kind which popular rumour expected him to solve. Before long, however, he had settled down to a good and varied programme of important but relatively long-range researches, gathering round him a group of collaborators whose training could supplement at different points what was lacking in his own. There was no further discovery like that of insulin, but he and his group did work of substantial and permanent value, for example, on the difficult problem of silicosis, which was a matter of growing concern to the mining industry of Canada.

Whenever I met Banting in these more recent years, before the war broke out, I was impressed not only, as always, by his native keenness and alert intelligence, but by his steadily maturing judgment, and by the essential modesty and quiet firmness of his character. It is idle to speculate as to what he might have achieved if he had lived into a further period of normal activity. The war diverted him, like others, to abnormal duties. A deep glow of patriotic devotion to the British Empire and to Canada was always a central motive with him, and I think that he would have been content if he had known that death on national duty was before him. Apart from the relief and the new prospect of useful life which insulin has given to unnumbered sufferers from diabetes, it is a commonplace that its discovery has had a revolutionary effect on the progress of knowledge concerning the nature of normal carbohydrate metabolism. Perhaps it is not so generally recognized how much wider its influence has been. In 1921 only two relatively simple and stable hormones, adrenaline and thyroxine, had been chemically isolated. Secretin and the post-pituitary hormones, being thermostable and of comparatively small molecular dimensions, had been obtained in extracts, but attempts at their further isolation had ended in discouragement. For the rest, the endocrine function of the other ductless glands was itself little more than a deduction from the results of extirpation and grafting. Their hormones, it was supposed, might be too complex and unstable to be handled, or they might be secreted as fast as they were formed, without accumulation of a store which could yield an active extract. The possibility of progress towards their isolation and chemical study seemed depressingly remote. The separation of insulin from the pancreas was not only an achievement in itself; it had an immense effect of encouragement to workers over the whole field of endocrinology. The whole position has since been transformed at a rate which would have seemed incredible in 1921. Other previously hopeless conditions of endocrine deficiency have been brought under successful treatment, and a number of hormones whose very existence was then a matter of inference have now been not only isolated but even made by artificial synthesis. In paying our tribute to the memory of Frederick Banting, for ever to be associated with the discovery of insulin, it seems fitting that we should remember also the stimulating influence of that discovery on so much that has followed.

H. S. BEADLES, M.R.C.S., L.R.C.P.

The news of the death of Dr. H. S. Beadles, which took place at Romford on February 23 after a long illness, will be received with regret by a wide circle of British Medical Association members, not only in his own locality—London over the Essex border—but throughout the Metropolitan Counties Branch.

Harold Shatford Beadles, the son of a general practitioner, was born in 1870, and received his medical education at University College and Hospital, London. After taking the

Conjoint diplomas in 1893 he gained some experience as an assistant, and then, in 1896, acquired a large practice in Barking Road, which became larger as the district grew to realize what a careful and conscientious practitioner he was. He was also appointed a factory surgeon under the Home Office for the important industrial area in which his practice was situated, and was entrusted by that Department with many responsible duties over a period of twenty-five years.

When the National Health Insurance Act came into operation in 1913 Beadles found his most fruitful field of service for the profession and the public alike. From the beginning he was a member of the West Ham Insurance and Panel Committees, and his thorough knowledge of the Act and Regulations made his advice of great value. To him it was due in large degree that West Ham became one of the best administered insurance areas in England. Failing health compelled him to retire from active practice in 1922, but he retained his membership of the Insurance Committee and passed its chair. He also continued to take his full share in the divisional and central work of the British Medical Association.

His first appearance as a representative was in 1913, and for many years thereafter he was a well-known figure at the Annual Representative Meetings, and an occasional, always matter-of-fact, participant in its debates. He became a member of the Council in 1919, and, with an interval of one year, so remained until 1934. The number of central committees and subcommittees on which he served was above twenty. His longest term, extending from 1920 to 1934, was on the Insurance Acts Committee, and he was a member of the Medico-Political Committee for about the same period. On the Organization Committee he served for nine years, specially interesting himself in Association work for medical students. His work for his Division was equally noteworthy. For many years Stratford meant Beadles, and Beadles meant Stratford. After the last war, at a time when the reorganization of medical services was very much in the air, he induced Lord Dawson of Penn to address the Stratford practitioners and kept the debate going until after midnight. He was honorary secretary of the Division from 1917 to 1933. In 1929 he was elected to the chair of the Metropolitan Counties Branch, of which he had for several years been treasurer.

One of the hardest of workers, Beadles managed to convey an impression of casualness and nonchalance. A man as well versed in medical politics as any man of his time, especially in the technicalities of health insurance, he was content to be just a member of committees, never striving for the limelight. He was a man who needed knowing. Thirty years of close acquaintance with hard industrial life on the east side of London takes the frills away from a man, but his intimates knew him as a "jolly good fellow," and the fact that he was one of the two or three who arranged year after year that lively function, the dinner which followed the Annual Panel Conference, speaks for his social gifts. During the last six years Headquarters had scarcely seen him: the handicap of ill-health proved too much for him.

Dr. LESLEY MAUDE CAMPBELL PROBYN was killed when a London air-raid shelter of which she had medical charge was hit by a heavy bomb one night in February. She was educated at University College, London, and Charing Cross Hospital, and qualified M.R.C.S., L.R.C.P. in 1926. She was in practice in London and had filled the post of second house anaesthetist at Charing Cross Hospital. She had spent every night since the heavy raids on London began touring the many shelters in the district. Dr. Lesley Probyn joined the British Medical Association in 1928. She has died serving her country just as much as if she had been killed in action.

We record with regret the death on February 9, at a nursing home at Torquay, of Dr. ARTHUR JOHN WHITING, consulting physician to the Prince of Wales's General Hospital, Tottenham, and formerly dean of the North-East London Postgraduate College. He was born at Beverley, Yorks, on March 16, 1865, and studied medicine at the University of Edinburgh, graduating M.B., C.M. in 1889 and winning a gold medal at the M.D. examination in 1892, after which he served for a time as assistant to the professors of physiology and of clinical medicine. At Edinburgh he won the Murchison scholarship in clinical medicine and the Goodsir prize. Coming to London, Whiting held the posts of house-physician and medical registrar at Queen Square, and was later appointed physician to the City Dispensary in College Street. He obtained the M.R.C.P. diploma in 1896, and was for many years a member of the medical staff of the Prince of Wales's General Hospital; he was also physician to the Mount Vernon Hospital for Consumption until the building at Hampstead passed into the hands of the Medical Research Council and the hospital entered on a different phase of work at Northwood. For two or three years at the beginning of this century Whiting held the part-time post of subeditor of the *British Medical Journal*, before the reorganization of editorial duties. His name appeared on the title-page of several editions of *Aids to Medical Diagnosis*, the last being published only this year. He had been a member of the British Medical Association since 1893, and by reason of his experience as honorary secretary of the Fellowship of Medicine he was asked to serve on the Postgradute Courses Committee of the B.M.A. in 1921.

By the death on February 22 of JAMES BATES WILKINSON, M.D., C.M., medical officer of health for Oldham for thirty-eight years, there passed on one who in his day and generation did probably more for the health of the county borough than any other individual. Dr. Wilkinson was born at Godmanchester, Huntingdon, and studied medicine at Edinburgh, graduating in medicine and surgery in 1883, and proceeding M.D. two years later. After holding a post as demonstrator of pathology in the University, he obtained experience of general practice in London, Peterborough, and Manchester, and started practice for himself in Oldham in 1887, during which time he qualified for the D.P.H. of Manchester University. He was appointed M.O.H. for Oldham in 1898, and held this post until his retirement in 1936. He was also superintendent school medical officer from 1906 to 1936, and consulting county medical officer for Huntingdonshire from 1898 to 1911. He lectured in public health subjects for many years at the College of Technology, Manchester. Dr. Wilkinson always took a keen interest in the work of the professional societies associated with his branch of the profession. He had been a member of the British Medical Association since 1886, and acted as representative in the Representative Body when the Association met in Liverpool in 1912. He was a past president of the Institute of Sanitary Engineers. In his early days as M.O.H. Dr. Wilkinson was much attracted to the scientific side of sewage disposal, and gave evidence before the Royal Commission on this subject. He always took an active part in charitable matters, and was a founder-member of the Oldham Rotary Club. Perhaps his greatest interest outside his work was, however, the Order of St. John of Jerusalem and its associated body the St. John Ambulance Association. He was awarded several medals and decorations for his services in connexion with the Order of St. John, being finally awarded the high order of Knight of Grace. Dr. Wilkinson was proud of the fact that he, his son, and his daughter, Dr. Gladys Wilkinson, all received the medal commemorating the Jubilee of King George V.

The following well-known foreign medical men have died: Dr. ANTON SCHNÖLLER of Davos, a tuberculosis specialist, said to have been one of the first physicians to practise artificial pneumothorax, died at Zurich, aged 75; Dr. ADOLPHE LUTZ, for many years chief of the department of medical zoology at the Instituto Oswaldo Cruz, Rio de Janeiro, aged 84; and Dr. DÉSIRÉ GLIBERT, a Belgian physician and one of the leading men in industrial hygiene in Europe.

G. L. Hallez (*Nourrisson*, 1940, **28**, 22) records a case of paratyphoid A in a male infant aged 1 year which is remarkable owing to the rarity of the disease at that age. The fever continued until the ninth day, when some rose spots appeared. There were no other signs of the disease and the spleen remained normal. Recovery took place. The father, who was a nurse in a fever ward, may have acted as a carrier.

The Services

MEDICAL DIRECTOR-GENERAL OF THE NAVY

Surgeon Rear-Admiral Sheldon F. Dudley, C.B., O.B.E., F.R.C.P., K.H.P., has been appointed Medical Director-General of the Navy in succession to Surgeon Vice-Admiral Sir Percival T. Nicholls, K.C.B., F.R.C.S., K.H.P., from July 2, 1941.

DIRECTOR-GENERAL OF MEDICAL SERVICES, AIR MINISTRY

Air Vice-Marshal H. E. Whittingham, C.B.E., F.R.C.P., K.H.P., has been appointed Director-General of Medical Services, Air Ministry, in succession to Air Marshal Sir Victor Richardson, K.B.E., C.B., M.B., D.P.H., K.H.S., from March 1, 1941.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Missing, Presumed Killed

In an Admiralty casualty list, published on March 3, the names of Surgeon Lieut. W. Boyd, R.N., Surgeon Lieut. F. H. Williams, R.N., and Probationary Temporary Surgeon Lieut. H. F. Sloan, R.N.V.R., are included as "Missing, Presumed Killed."

Surgeon Lieut. WILLIAM BOYD was educated at Glasgow University and graduated M.B., Ch.B. in 1932. In the same year he joined the British Medical Association.

Surgeon Lieut. FRANK HANSON WILLIAMS took the L.M.S.S.A. and the L.A.H. in 1933, and had been a member of the British Medical Association since 1934.

Probationary Temporary Surgeon Lieut. HAROLD FITZGERALD SLOAN was educated at Dublin University, where he graduated M.B., B.Ch., B.A.O. in 1937. His home was at Kilmainham, Dublin.

Injured and Wounded

Temporary Surgeon Lieut. Maximillian Raphael Julius Behrendt, R.N.V.R.

Probationary Temporary Surgeon Lieut. Richard George Sarel Whitfield, R.N.V.R.

ROYAL ARMY MEDICAL CORPS

Major JOHN FRANCIS BOURKE, M.C., lost his life at sea by enemy action in January. He took the Scottish triple qualification in 1913 and served during the war of 1914–18, being mentioned in dispatches in 1916 and receiving the Military Cross. He attained the rank of major in 1927 and was invalided out towards the end of 1940. He had just served a term of duty in India and was recently stationed at Quetta, and was on his way home when he met his death. He had been a member of the British Medical Association since 1928.

DEATHS IN THE SERVICES

Surgeon Captain CHARLES JAMES EDWARD COCK, R.N. (ret.), died at Exmouth on February 22, aged 68. He received his medical education at Charing Cross Hospital and qualified M.R.C.S., L.R.C.P. in 1894. Entering the Royal Navy soon afterwards, he became surgeon commander in 1909 and retired with an honorary step in rank as surgeon captain in 1923. He served during the war of 1914–18, receiving the medals, and the President of the Czecho-Slovak Republic conferred upon him the Croix de Guerre in recognition of services rendered during the war.

Colonel EUSTACE AUGUSTUS BURNSIDE, late R.A.M.C., died at Paisley on February 17, aged 80. He was born at Nassau, in the Bahamas, on September 24, 1860, the eldest son of the late Sir Bruce Burnside, was educated at King's College, London, and took the M.R.C.S. and L.S.A. in 1886. Entering the Army as surgeon in 1887, he became lieutenant-colonel in 1911, colonel in 1915, and retired in 1917. He served in the South African War of 1899–1902, when he took part in the actions at Elandslaagte, Rietfontein, and Lombards Kop, and in the defence of Ladysmith, also in the subsequent operations in Natal, the Orange River Colony, and the Transvaal, and received the Queen's medal with four clasps and the King's medal with two clasps. He also served in the war of 1914–18. In 1917 he was appointed a Knight of Grace of the Order of St. John of Jerusalem. He had been a member of the British Medical Association for thirty-two years.

Colonel EDWARD MORESBY HASSARD, late R.A.M.C., died at Hindhead on February 20, aged 78. He was born at Hilsea on November 10, 1862, the youngest son of the late Major-General F. Hassard, C.B., R.E., and received his medical education at St. Bartholomew's Hospital, taking the M.R.C.S., L.R.C.P. in 1886. Entering the Army as surgeon in 1887, he became lieutenant-colonel in 1911, colonel in 1915, and retired in 1919. He served on the North-West Frontier of India in the Isazai campaign of 1892; in West Africa in the Lagos campaign of 1897–8, when he was mentioned in dispatches and received the African medal with a clasp; in operations in Sierra Leone in 1898–9 (clasp); in the South African War of 1899–1902, in operations in the Transvaal, in the Orange River Colony, and in Cape Colony (Queen's medal with three clasps and King's medal with two clasps); and in the war of 1914–18, when he received the Portuguese Order of Avis as commander. He had been a member of the British Medical Association for thirty-four years.

Lieut.-Colonel REGINALD JOHNSON, M.B.E., R.A.M.C., died on February 4, aged 52. He was born on September 12, 1888, and was educated at Trinity College, Dublin, where he graduated M.B., B.Ch., B.A.O. in 1912, proceeding M.D. in 1914. He entered the R.A.M.C. as a temporary lieutenant in 1916, became temporary captain a year later, and took a permanent commission in 1920. He became major in 1928 and had recently been promoted to lieutenant-colonel. He had lately been stationed at Quetta.

Universities and Colleges

UNIVERSITY OF OXFORD

The following medical degrees were conferred on March 1:

D.M.—R. N. B. Cridland, N. L. Rusby.

B.M.—J. C. Pease, J. B. Wilkinson, R. B. Buzzard, J. J. Pritchard.

UNIVERSITY OF CAMBRIDGE

The Rockefeller Foundation has agreed to continue until the end of 1941 its grant of £1,200 a year for research in cellular physiology at the Molteno Institute under the direction of Prof. Keilin.

In Congregation on March 1 the Senate resolved to confer the degree of Master of Arts upon Leicester Hammond Aitken, M.B., B.Ch.N.Z., F.R.C.S.Ed., university demonstrator in anatomy.

The following medical degrees were conferred on March 1:

M.B., B.CHIR.—(By proxy). W. W. Brigden, C. E. Watson, S. C. Gold, F. A. Whitlock.

UNIVERSITY OF LONDON

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

Entrance Scholarships and Exhibitions

Two Goldsmid Entrance Scholarships, entitling the holder to the final course of medical study, are offered for competition in July and are open to students who are preparing for the degrees of the universities of London, Oxford, Cambridge, Durham, or other British universities, or for the diplomas of the Royal Colleges of Physicians and Surgeons; also one Goldsmid Entrance Exhibition, entitling the holder to a reduction by £80 of the fees due for the full course of final medical study; and the Filliter Entrance Scholarship in Pathology, entitling the holder to a reduction by £52 10s. of the fees due for the full course of final medical study. Entries must reach the Secretary, University College Hospital Medical School, University Street, W.C.1, by July 5, and applications for further particulars should be made to the same address.

UNIVERSITY OF ABERDEEN

On February 26 the Senatus agreed to confer the honorary degree of LL.D. on Prof. Arthur Wellesley Falconer, C.B.E., D.S.O., M.D., F.R.C.P., Principal and Vice-Chancellor of the University of Capetown.

UNIVERSITY OF EDINBURGH

At a meeting of the University Court on February 24 Prof. A. Patrick and Prof. J. Hendry were appointed external examiners in systematic medicine and systematic midwifery and gynaecology respectively.

Prof. J. R. Learmonth was appointed a member of the Lister Memorial Committee of the Royal College of Surgeons of England for the award of the Lister Memorial Prize and Medal for 1942.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

The following have been elected to the Fellowship of the College:

William Cunningham Armstrong (Glasgow), Norman Llewellyn Edwards (Derby), Alistair Livingston Gunn (London), Joan Kennedy Rose (Edinburgh), Wentworth Alexander Taylor (Birmingham), Robert Watson (Northampton).

Medical Notes in Parliament

Increase in Road Accidents

The BISHOP OF WINCHESTER, in the House of Lords on February 25, said that since the war started road casualties had exceeded the worst previous figures. In the last four months of 1940 persons killed numbered 4,380, of whom 496 were children. In January the number killed dropped to 741, of whom sixty-three were children. In parts of the country during January the roads could not be used for motor traffic. Totals of non-fatal accidents on the roads were not now published; judging by the proportion between deaths and injuries before the war, the 8,600 killed on the roads in 1940 were accompanied by 250,000 injured, including 70,000 seriously injured. Over half the accidents occurred during the black-out, but in the last months casualties during the black-out had diminished while those in daylight had steadily increased. Comparing the last three months of 1940 with the last three months of 1939, the increase in casualties in daylight had been 63%. Casualties at night had been considerably but not correspondingly reduced. No legal claim could be made by hospitals for persons injured by military vehicles; the hospitals were anxious to know whether they would get compensation from the War Office. The police and the Post Office had agreed that they would not claim exemption, and would pay compensation if accidents occurred through the driving of vehicles by their employees. The hospitals hoped the War Office would take the same line.

LORD SNELL said that in the Metropolitan Police District there was an increase of 100% in the number of pedestrians killed in the winter months of war compared with the corresponding winter months of 1938–9. For motor cyclists the increase was 77%. Motor drivers caused fewer casualties, and those of pedal cyclists had decreased until this winter. Casualties had increased on roads not subject to speed limits, and daylight casualties had increased on all roads. With regard to military accidents, no Crown vehicles were insured, and there was no proposal at present to alter that. Taking November and December, 1940, as a period of observation, the Secretary for War had acknowledged that 300 accidents a day due to military vehicles was unsatisfactory. Special instructions had been issued to Commands about care on the roads. There for the moment they must leave that matter. Better street lighting was practicable, consistently with air-raid precautions, and would be considered before the next winter period. Safety instruction among children was being resumed.

Fracture Treatment and Rehabilitation

Dr. MORGAN asked Mr. Ernest Brown on February 20 what steps were being taken to secure modern and adequate fracture treatment of industrial injured workers, and whether the organization of such treatment would be on the lines recommended by the British Medical Association Committee and by the Delevingne Interdepartmental Committee in approved fracture clinics in hospitals or other centres. Mr. BROWN announced that in conjunction with the Minister of Labour and the Secretary of State for Scotland he was considering the better organization of facilities for the treatment of fractures, the rehabilitation and, where necessary, the re-training of injured industrial workers. He would make a further statement as soon as possible.

Voluntary Hospitals and the War Damage Bill

Moving the third reading of the War Damage Bill in the House of Commons on February 26, Sir KINGSLEY WOOD said with regard to voluntary hospitals that it would be the duty of the War Damage Commission to consult with the Minister of Health. That Minister assured him that if he was consulted on questions affecting voluntary hospitals he, for his part, would consult the organizations representing the voluntary hospitals movement, such as King Edward's Hospital Fund, the British Hospitals Association, and particular hospitals concerned. The base of the scheme would be full, cordial, and close co-operation. The Government would decentralize the administration of the scheme and would open offices in the towns in which were situated Civil Defence Regional Commissioners. Four regional offices would be set up in the London area.

Shelter Conditions

Replying to Captain Cunningham Reid on February 27, Miss WILKINSON said local authorities had used their powers to close shelters which were damp and trenches which had fallen in. In London a number of trenches had been closed. Where official shelters under local authorities had been closed the police had power to deal with persons who visited them. The Ministry of Home Security recognized that large shelters invited tragedy, and encouraged people to stay in their homes or to use small surface shelters. On February 5 the Horder Committee submitted recommendations on the matter, which were being considered. The Ministry might ask the House for a new Defence Regulation, giving power to turn people out of places where they ought not to go. Mr. EVELYN WILKES hoped Miss Wilkinson would persuade local authorities to improve the sanitation and lighting of surface shelters. Miss WILKINSON said everything should be done to persuade the people that the surface brick shelters were useful.

Estimated Expenditure on Health Services

Estimates are issued for the financial year which will end on March 31, 1942. These include provision of £24,646,200 for the Ministry of Health, against £23,891,724 in 1940–1; £208,962 for the Board of Control, against £184,216; £4,384,544 for the Department of Health for Scotland, against £4,295,319; £20,300 for the Board of Control, Scotland, against £17,827; £106,900 for Broadmoor Criminal Lunatic Asylum, against £93,664. Token votes of £100 each are asked for the war services of the Ministry of Health and the Department of Health (Scotland).

Compulsory Evacuation of London Children.—The Minister of Health told Miss Cazalet on February 27 that the number of children who, after medical examination under the new Order, had been compulsorily evacuated was six. It was expected that where the evacuation of a child was shown to be desirable on medical grounds the parents would normally agree and recourse to a compulsory Order would be unnecessary. The total number of children evacuated in this way was unlikely to be large, since the health of children in London remained good. Out of 395 children inspected in shelters in Kensington, the examining doctor was prepared to certify fourteen for compulsory evacuation; all fourteen were being sent away voluntarily

Notes in Brief

Up to February 26, 28 civilians—19 men and 9 women—had been reported in hospitals in the United Kingdom with injuries from enemy action which resulted or were likely to result in blindness.

On February 18 Miss HORSBRUGH informed Sir Thomas Moore that there was no general shortage of blood donors, but in certain areas more were needed. Local campaigns were being organized in those areas.

Between July 1, 1940, and January 31, 1941, the total number of amputations in civilians due to injury by enemy action was 776. The number of recorded cases of eye injury of a kind necessitating removal since the outbreak of war was 191.

The twenty-first annual report of the James Mackenzie Institute for Clinical Research at St. Andrews is a brief document of twelve pages, and half of those are given up to the financial position, which is very serious. In order to meet ordinary expenditure investments have had to be realized, with consequent loss of income. On an income of less than £1,000 the Institute has made every effort to carry on the work as in pre-war days, and this has been possible in the children's department, where forty-six clinics were held during the year, and 674 children attended; in the laboratories, and in the x-ray department. Under the blood transfusion service, 154 volunteer donors have had their blood typed during the year. The clinical research fund makes grants for research out of the income from a trust provided by an anonymous donor. An appeal is made by Prof. David Waterston, the chairman of the council, for financial help for the work founded by the late Sir James Mackenzie.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

Pneumonia (primary and influenzal), dysentery, and cerebrospinal fever have increased in incidence during the week. Whooping-cough, diphtheria, and scarlet fever declined slightly and measles considerably.

Cerebrospinal Fever

Compared with the beginning of last year cerebrospinal fever has been unusually prevalent, as is shown by the figures for the first eight weeks for both years (figures for 1940 in parentheses): 229 (52); 266 (107); 293 (142); 303 (190); 331 (295); 345 (402); 378 (560); 434 (586). More important than total numbers over a given period is the rate of increase, which was very steep last year, reaching its peak at the end of March, when weekly notifications reached the high level of 623. The more gradual development of the present epidemic is in itself a favourable sign, but the notifications are high in certain areas. Present conditions favour the spread of the disease. During the week more than five cases were recorded in: Lancaster 63; London 32; West Riding of Yorkshire 23; Chester 18; Southampton 17; Glamorgan and Warwick 16 each; Middlesex 13; Essex 12; Flint 10; Gloucester and Surrey 9 each; Kent 8; and 6 each in Berkshire, in both East and North Riding of Yorkshire, in Monmouth, and in Stafford.

In Scotland, so far, notifications have remained below those of the previous year; the rate of increase for both years is approximately equal.

Diphtheria Immunization in Scotland

The experience of the diphtheria immunization campaign conducted in Edinburgh in the last three months presents certain features of interest. Of the total of 26,131 children immunized to date, 12,153 were inoculated in first-aid posts, 3,737 in schools, 2,842 at child welfare centres, and 7,399 in private practice. Although the number dealt with so far (close on 30,000 if 3,000 treated during an experimental period before the campaign are included) is only one-half that originally aimed at, and the use of first-aid posts has been discontinued, the campaign is being pressed home, for half-measures exert but little effect on the prevalence of the disease and may, under certain conditions, actually constitute a threat to the unimmunized; attempts should be made to protect at least 75% of the child population.

Influenza for Week Ending February 22

In the week ending February 22 314 deaths were ascribed to influenza in the great towns, 10 fewer than in the previous week. The age distribution of the deaths continues to be normal—54.1% of the deaths are at ages over 65 and 6.4% at ages under 25. In the County of London the deaths have decreased from 50 to 26 and hospital admissions from 526 to 379 (influenza, bronchitis, pneumonia). The proportion of total deaths coming from the South-Eastern Area (including Greater London) has decreased to 35.2%.

Total of Influenza Deaths and Deaths in Age Groups in 126 Great Towns for Week Ending February 22

All Ages	A Under 1 year	B 1-5	C 5-15	D 15-25	E 25-35	F 35-45	G 45-55	H 55-65	I 65-75	J 75 and over
314	9	9	2	7	6	19	33	59	89	81

Regional Totals of Influenza Deaths for Week Ending February 22

South-Eastern Area:		Midland Area	81
Greater London	95	Eastern Area	5
Rest of S.E.	27 = 122	South-Western Area	4
Northern Area	106	Wales and Monmouthshire	29

Total for 126 Great Towns, including the Outer Ring 347

We are not entitled to assume that a further increase in the great towns will not occur—namely, that the epidemic has spent itself. But it is now improbable that this winter's mortality will be as great as that of last year and very improbable that a major recrudescence will occur.

No. 6

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended February 8, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales, (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	(b)	(c)	(d)	(e)	1940 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Medical News

Sir Arthur Keith has been elected an honorary member of the New York Academy of Sciences.

Prof. Geoffrey Jefferson, F.R.C.S., and Mr. A. Tudor Edwards, F.R.C.S., have accepted appointments as honorary consultants to the Ministry of Pensions at the invitation of the Minister.

The name of Dr. Ernest Berry Garrett, medical officer, A.R.P. Casualty Service, Leicester, has been brought to notice for brave conduct in civil defence.

The next meeting of the Shaftesbury Military Hospital Medical Society will be held at the hospital on Tuesday, March 11, when Major W. C. Somerville-Large, R.A.M.C., will speak on "The Army's Feet."

At a meeting of the Pharmaceutical Society of Great Britain, to be held on Thursday, March 13, at 2.30 p.m., at 17, Bloomsbury Square, W.C., an address entitled "Recent Developments in Pharmaceutical Practice" will be given by Mr. H. Berry, B.Sc., dean of the Society's college. It will include a discussion on present knowledge of the problems concerned with the preparation of solutions for parenteral injection, their sterility and stability; and the need for further investigations of the stability of pharmaceutical preparations will be stressed.

A general meeting of the Tuberculosis Association will be held at 26, Portland Place, W., on Saturday, March 15, at 10.30 a.m., when Dr. W. E. Snell will read a paper on "Senile Tuberculosis," and a discussion on "Current Topics" will be opened by Dr. F. T. Clive, followed by Dr. J. Glyn Jones.

The home of Lord and Lady Melchett, Colworth House, Sharnbrook, near Bedford, was opened on March 1 by Mrs. Rex Benson, representing the British War Relief Society of New York, as a rest home for London's voluntary hospital nurses. The hon. secretary of the home is Mr. Charles M. Power, and inquiries in regard to it may be addressed to him at Westminster Hospital, St. John's Gardens, London, S.W.1.

The issue of the *South African Medical Journal* for December, 1940, is devoted to syphilis. In this C. K. O'Malley records that there are five times more cases of early syphilis among Europeans in Capetown than in Stockholm (Capetown 0.9, Stockholm 0.18, per 1,000 of population), and there are twenty times more cases of congenital syphilis among the European population in Capetown than in Stockholm (Capetown 0.19 and Stockholm 0.01 per 1,000 of population).

The current issue (September, 1940) of the *Chinese Medical Journal* is devoted to the history of Chinese medicine.

The recently published August–September issue of *Tubercle* contains a supplement on tuberculosis in wartime.

Messrs. Oliver and Boyd, Ltd., Tweeddale Court, Edinburgh, and 98, Great Russell Street, London, W.C., have been appointed publishers to the Royal Society of Edinburgh. Copies of previous issues of the *Transactions* and *Proceedings* and of all future publications of the Society will now be supplied by this firm, to whom all inquiries should be sent.

Full details of the arrangements that have been made for the provision of spectacles as part of the treatment of patients under the Emergency Hospital Scheme are contained in a circular (No. 2240) from the Ministry of Health to all local and hospital authorities concerned in the Scheme and to medical officers of health. The arrangements apply to members of the Services and those civilians (*a*) who have suffered injury through enemy action or in carrying out civil defence duties, and for whom spectacles are required to correct defective vision or changes in vision caused by the injury, and (*b*) who are receiving in-patient treatment under the Emergency Hospital Scheme and for whom spectacles are necessary for the efficient treatment of the condition for which they were admitted.

Owing to the war the annual report of the Family Planning Association for 1939–40 gives only a brief statement of the past year's work and present plans, and appears as a four-page leaflet. The association, of which Lord Horder is president, has been able to keep its headquarters in being and to carry on from this at least part of its usual work. The wartime office is at 190, Old Christchurch Road, Bournemouth, and part of the usefulness of the organization is maintained through the kindness of the Eugenics Society at the London offices, 69, Eccleston Square. The Medical Subcommittee continues to examine the value of present contraceptive methods and to report on the results to members of the medical profession and other inquirers. It also endeavours to overcome difficulties in the supply of contraceptives which are due to war conditions.

Ripley Court, an early eighteenth-century country house in Surrey, has been taken over by Westminster Hospital as a maternity home and teaching centre, in conjunction with the Surrey County Council, which has reconditioned the house, and the Westminster City Council ante-natal clinics. Westminster Hospital is providing complete equipment for a unit of 25 beds, with medical and nursing staff. The home was opened on January 8.

The Ministry of Labour and National Service has made regulations prescribing standards of lighting in certain classes of factories. These are substantially similar to those issued in draft last autumn, the main difference being that the list of classes of works of a special character in the schedule to which the Regulations apply only in a somewhat modified way has been extended. The Regulations came into force on February 1.

Dr. Arnulfo Arias, a distinguished physician of Panama who had previously held the posts of Director of the Department of Hygiene and Minister of his country in Italy, France, and England, has recently been appointed president of the Republic of Panama.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology, Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Treatment of Night Sweats

"J. N. T." would be grateful for any suggestion about the treatment of heavy night sweats in an obscure case. There is no evidence of heart disease. The patient has a slight cough but no sputum. There is no evidence of lung disease. There is a nocturnal rise of temperature to 99° or 100° F., which is followed by a drenching perspiration lasting for two or three hours. On two or three occasions there had been symptoms and signs resembling mild Addison's disease—feelings of exhaustion, low blood pressure, and patches of pigmentation in the skin. The urine is normal. The patient has not had malaria. There is undoubtedly a psychological element in the case. So far the injection of atropine has helped to control the perspiration, but the condition still persists.

Local Treatment of Herpes Zoster

DR. PATRICK DUFF (Ballyshannon) writes: I was interested in reading a letter by Dr. A. H. Bartley on treatment of herpes zoster (January 4, p. 38). For some time I have received very excellent and immediate results by local treatment of the erup-

tions by tannic acid jelly (amertan, Lilly) and radiant heat in the same manner as in the treatment of burns. I have also found similar treatment valuable in a case of pemphigus. A male patient aged 76 years was admitted to hospital with widespread pemphigus vulgaris, and although various remedies were tried his condition was becoming worse. He was put on local applications of tannic acid jelly as described above, and this produced a marked improvement in the eruptions and gave the patient great relief. He was later put on calciferol as recommended by H. King and C. M. Hamilton, New York. After six weeks on the above treatment the skin lesions have cleared up with no recurrence of bullae.

Income Tax

Retirement

"J. C." retired on September 30, 1940. How should he calculate his liability? (It is understood that his previous assessments have been on the "cash basis.")

*** His liability for 1940–1 is in respect of the profits for the period from April 5, 1940, to September 30, 1940, only; he should prepare a statement on the usual lines (cash receipts and payments apparently) for that period. If this produces a balance of profit that is clearly insufficient for a six-months account—for example, by bringing in as an expense two half-years' rents instead of one—the inspector of taxes may require an account on the "earnings" basis.

Partnership—Acquisition of Partner's Share

"GAMMA" has taken over his late partner's three-fifths share as from October, 1940, and is employing an assistant. It may be assumed that the profits of the practice will be less than in the past. The assessments have been on the basis of cash receipts; cash for the old firm's debts is not coming into the "new practice" accounts.

*** The simplest method is for "Gamma" and his late partner to elect to have the practice regarded as having ceased and recommenced as a "new" one. As regards the old firm the effect will be that the assessment for 1940–1 will be reduced to the amount of the profit for the period from April 5, 1940, to the date of dissolution; also, if the assessment for the year to April 5, 1940, was less than the amount of the profits for *that* year, then the assessment can be increased to bring it up to the actual profit amount. As regards the "new" firm, "Gamma" will be assessable for the period from the date of dissolution to April 5, 1941, on the amount of his earnings for that period, and for the year to April 5, 1942, on the amount of his first twelve months' earnings. In either case the result should be equitable.

Expenses of Removal, Renewals, and Insurance

"J. M." inquires whether the following are allowable expenses: (*a*) cost of removal to present location, and (*b*) renewals of waiting-room carpets and linoleum. He also asks for advice as to a "cost of replacement" insurance policy for the house and contents.

*** (*a*) Not allowable; (*b*) allowable. As to the question of insurance we cannot recommend a particular company, but suggest that "J. M." might communicate with the Medical Insurance Agency.

Half Pay during Instruction Course

"G. H" has been appointed to the Colonial Service, but is required to take a full-time course in tropical medicine, during which he receives half pay. Is this liable?

*** Cases of this type depend on the wording of the Service agreement; prima facie we should regard the half pay as liable. The similarity with non-taxable subsistence allowance is not very close as such an allowance is given for additional expenses while in receipt of taxable pay. The point may be worth taking up with the taxing authority, but we should not advise an appeal.

Purchase of Practice

"D. C." was working as a locumtenent from April 6, 1939, to October 15, 1939, from which date he acquired the practice. What should be the basis of his liability for 1939–40 and 1940–1?

*** It has to be borne in mind that the previous year's basis does not apply where an employment ceases or to the first year or two years of a new practice. As a result the basis for the years in question in this case becomes:

1939–40—The earnings of the actual year—i.e., £730.
1940–1—The amount of the profits of the first year of the practice after "D. C." took it over—i.e., £1,107.

If, however, "D. C." wishes the assessment for 1940–1 and each of the two following years can be based on the earnings of the actual year; but he cannot choose between those years, the "actual-year" basis if applied must be applied to all three years.

LETTERS, NOTES, ETC.

Bell's Palsy and Herpes Zoster

Dr. G. LLEWELLYN DAVIES adds the following note to his letter published last week under the title "Bell's Palsy and Herpes Zoster": My patient with the herpes and the Bell's palsy did complain of an intense pain in the ear on the same side as his other symptoms. He reminded me of this yesterday, but the rush of work prevailing at the time did not enable me to assess the true value of this symptom, and my rather cursory examination of the ear evidently did not reveal any vesicles. Had I tumbled to the true pathology of the condition I should probably have used an aural speculum.

Bran in the Prevention of Constipation

Dr. M. E. LAMPARD (Colchester) writes: Apropos the letter from Dr. F. Parkes Weber (February 15, p. 252) about all-bran, many of my patients have been using ordinary bran for the last few years, with excellent results. We have also consumed it in our own household. It is advisable to buy it from a miller, as when it is stored in corn merchants' shops it is apt to contain weevil. It can be taken well wetted with cold milk and with porridge added.

Naming of New Drugs

Mr. CHARLES ALEX. HILL (Managing Director of the British Drug Houses Ltd.) writes: In the note appearing in the *Journal* of February 22 (p. 280) the writer is undoubtedly correct in stating that "great difficulties attend alterations in nomenclature of drugs"; but I think that he has slipped slightly in suggesting, as I think he does, that we have shown inconsistency by coining the names "anacardone" and "iodatol." The B.D.H. set up the manufacture of pyridine-β-carboxylic acid diethylamide so soon as the patent expired, and made it available to the medical profession in January, 1939. We could hardly market it under its chemical name, for this contains thirty-five letters, and the only existing short name then was a registered trade mark, the property of the patentee firm. We were obliged, therefore, to coin a new name, and "anacardone" was chosen as being both "appropriate" and "easily memorized." It was not until two years later that the substance was made official as "nikethamide" in the Third Addendum to the *B.P.* (January 1, 1941). To change over abruptly from the name "anacardone" to the name "nikethamide" would seriously inconvenience practitioners who have known and have been prescribing the drug as "anacardone" for the past two years. Similarly, the name "iodatol" for iodized oil was coined by us in 1914. Iodized oil was made official in the Addendum, 1936, to the *B.P.* (December 29, 1936)—twenty-two years later.

Friedländer's Pneumobacillus and Sulphapyridine

Dr. MORRIS CUTNER (Chelsea, S.W.) writes with reference to Surgeon Lieutenant Fraser Sinclair's clinical memorandum on the above subject (February 8, p. 196): Early in 1939, during the routine investigation of a chronic cough, a predominating culture of the pneumobacillus was obtained from the muco-purulent sputum. An attempt to treat this by sulphanilamide with the patient ambulant proving unsuccessful, the use of sulphapyridine was considered. An opportunity occurred when the patient was in bed with influenza. He was submitted to a full oral course of the drug. The influenzal condition improved within a few days, but the degree of cough and amount of sputum remained unaltered. Later a further examination confirmed the presence in the sputum of the pneumobacillus in undiminished amount.

Spasm of Sphincter of *Oddi*

"A.B.C." writes: My experience conflicts with that of your contributors who state that morphine in any form causes spasm of the sphincter of Oddi. For many years I have suffered from periodical attacks of spasm of this sphincter, resulting in an acute and very painful distension of the gall-bladder. This can be felt as a rounded tender prominence in the hypochondrium. Naturally, the pain—which is continuous and which simulates a painful indigestion—is insidious in its onset, but as soon as I am sure what is happening I give myself an injection of morphine grain 1/4 with atropine grain 1/100. This invariably has given complete relaxation and relief within fifteen to twenty minutes, the bile escaping with an audible gurgle; and as the attacks always come on in the late afternoon or evening and send me to bed, I am soon asleep. A sufficiently large dose of acetylsalicylic acid (gr. xv) will often relieve the condition if taken early in the attack. Fortunately there has been no recurrence for some months, and now I have nitroglycerin at hand if and when it does come.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MARCH 8 1941

OLD AGE WELFARE

BY

J. C. C. LANGFORD, M.R.C.S., L.R.C.P.

It is very natural that infant welfare has inspired much more interest than old age welfare, which may, by comparison, appear even depressing. But the latter subject is important. Moreover, the aged invalid has greater capacity for mental suffering than has the infant, and this fact should spur reformers to spend more time in consideration of the welfare of old people, and especially of *poor old people.*

The Poor Old Person

The lot of the average poor, or even moderately impecunious, old man or woman is not as happy as it ought to be. All too often the old person, suffering from chronic illness, is living a lonely life in one of those wretched semi-slums which are still such prevalent reminders in our suburbs of past gentility now gone to seed. Such places are so depressing as to have a deleterious effect on their unfortunate inmates.

Often the poor old person has been "parked" *on relatives.* Often the relatives are surprisingly unselfish and kind in their attentions, but it is very hard on a young and struggling married couple with several children to be burdened with, say, an elderly invalid aunt or uncle whom nobody else will have. Very often, too, the elderly, by reason of their infirmities, are awkward, stubborn, and testy. Capacity for self-sacrifice is a virtue to be extolled, but the demand for its employment may sometimes be unjust, unnecessary, and inadvisable; also there is a point beyond which youth should surely not be sacrificed to age. It follows that old age welfare is important not only to the aged but also to younger people indirectly.

Serious Illness in the Aged

One of the major problems in dealing with the aged poor arises when serious illness supervenes. Sometimes the patient may be treated fairly satisfactorily at his home with the aid of local district nurses. Not infrequently admission to a hospital may be advisable, if only for the reason that a visiting district nurse, however competent she may be, cannot always give sufficient time for some cases when much skilled nursing is required. It may happen, and especially in wartime, that it is not easy to obtain hospital accommodation for such cases, or elderly patients may be stubborn in their refusal to go into an institution of any kind, partly from a not unnatural horror of "institutionalism" and partly because they cling pathetically to the remnants of home—as if, by loss of contact with their belongings, however poor, they would lose touch with life itself. I think it right to stress the point that such difficulties are by no means confined to the *very* poor.

A Communal Plan

These problems of old age welfare could best be solved, in my opinion, by a system of blocks of "flatlets" arranged somewhat as follows:

The buildings should be pleasant, well built, and as *un*-institutional as the architects could make them. They should be situated in healthy localities, and surrounded by lawns and gardens. Lifts should be installed. Each old person or old couple should have at least two private rooms—one for sleeping and one for "sitting." These rooms, whenever possible, should be furnished by the tenants with their own possessions. There should be a resident trained nurse or nurses in every block. Remotely situated almshouses *without* such skilled resident nurses are of doubtful value in my experience. This point about resident nurses is most important, for it should thus be possible in many cases to avoid the necessity for removal to hospital, and the resident nurses would be able to give more time than the most conscientious of visiting district nurses.

Such blocks of flatlets, I suggest, should be supplied with communal kitchens, laundry rooms, a few isolation rooms, and a *common hall for entertainments. It would be most important* (1) to try to give all the advantages *of a well-run institution,* with (2) as little of the *institutional atmosphere* as possible. This may sound contradictory, but the meaning is *obvious.*

There are other points, of course, such as arrangements for medical attendance when required, and it would be an advantage if the visiting M.O. (for private or panel doctor) could have the right to call into consultation experts from the staff of the local county hospital in cases of serious obscure illness, when such consultations might obviate the necessity for removal to hospital for further investigation. Especially during war, but probably at any time, there is much to be said for building these blocks in country places, provided that the sites are not too remote from hospitals, bus services (for visitors), etc.

Perhaps the times may seem inopportune for discussion of this subject, but it is at least interesting to think out in advance *another way in which the lot of our fellow men and women* could be made much happier in the days which will follow war.

MEDICAL CERTIFICATES FOR NAVAL RATINGS

A certain amount of difficulty is being experienced by the Naval authorities in connexion *with medical certificates* granted in respect of Naval ratings by medical practitioners who are called in to attend *Naval men who fall ill when on* leave. It is essential for medical practitioners to certify on these occasions that *the Naval rating is unfit to travel.* This is required, as if the rating is fit to travel then it is necessary for *him* to go back to his ship or to a Naval hospital to receive treatment there. Failure to give the certificate involves a considerable amount of correspondence between the Naval authorities and the medical practitioners concerned, and valuable time would be saved on both sides if certificates were invariably to be made out in accordance with the instructions (which are fully explained on the back of each Naval rating's leave ticket).

The position of radiologists on the staffs of voluntary hospitals at which medical staffs are remunerated for E.M.S. work on the occupied-bed basis has been considered by the Advisory Emergency Medical Service Committee at the request of the Radiologists Group Committee of the B.M.A. On the subject of the special investigation or a second opinion given in the out-patient department in relation to a Service patient, the Advisory Committee has expressed the following opinion:

That, when a Service patient is referred by a Service medical officer to the out-patient department solely for the purpose of radiological examination and report, the whole fee of one guinea should be paid to the radiologist.

B.M.A.: Branch and Division Meetings to be Held

NORTH OF ENGLAND BRANCH.—At Newcastle-upon-Tyne, Thursday, March 13, 2.30 p.m. Prof. J. A. Nixon, "Chest Wounds from a Physician's Standpoint"; 3.45 p.m. Drs. A. E. W. McLachlan and Sydney Thompson, Clinical demonstration. Members of the Services stationed in the area of the Branch are invited to attend

SUSSEX BRANCH: BRIGHTON DIVISION.—At Hove, Thursday, March 13, 3 p.m. Clinical meeting. (Postponed from March 6.)

FIRE PREVENTION DUTIES

Medical practitioners are asking whether they are liable for fire prevention duties. The Civil Defence Duties (Compulsory Enrolment) Order, 1941, gives local authorities power to enrol local residents for compulsory fire prevention duties in the area. As a result of representations made by the British Medical Association the Ministry of Home Security has promised to take steps to exempt medical practitioners from registration and enrolment under this Order.

The Fire Prevention (Business Premises) Order, 1941, compels occupiers of business premises to make arrangements for fire prevention duties, but it is expressly stated that this Order does not apply "to any premises occupied by any person partly as his dwelling house and partly for the purpose of his business, trade, or profession." This proviso automatically excludes from liability under the Order medical practitioners whose surgeries are at their place of residence. There remains the case of a practitioner who has a lock-up surgery or who lives away from his surgery. He is liable to make arrangements for the protection of the premises, and he will do this in most cases by employing someone to undertake fire prevention duties.

Postgraduate News

The Fellowship of Medicine announces the following postgraduate courses for Final F.R.C.S. candidates: (1) orthopaedics (theoretical), lecture-demonstrations, illustrated by x-rays, on Wednesdays at 2.30 p.m., at Medical Society of London, 11, Chandos Street, W., March 26 to April 30; (2) comprehensive revision course at Royal Cancer Hospital, clinical and theoretical teaching, daily, 10 a.m. to 1 p.m., March 31 to April 25; (3) operative surgery, thrice weekly, 2 p.m., March 31 to April 25.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m., Post-mortem Demonstration. *Tues.*, 11 a.m., Paediatric Clinic, Dr. R. Lightwood. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical); 2 p.m., Historical and General Aspects of Shock, Prof. J. H. Dible; 3 p.m., Clinico-pathological Conference (Surgical). *Thurs.*, 2 p.m., Radiological Demonstration, Dr. Duncan White. *Fri.*, 2 p.m., Clinico-pathological Conference (Gynaecological).

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1 Wimpole Street, W.—*Brompton Hospital*, S.W.—Mon. and Thurs., 4 p.m., M.R.C.P. Course in Chest Diseases. *West End Hospital for Nervous Diseases.*—Tues. and Fri., 3.30 p.m., Clinical Demonstrations in Neurology. *Royal National Orthopaedic Hospital*, Stanmore.—Sat., 2.15 p.m., F.R.C.S. Clinical Orthopaedic Course. *Medical Society of London*, 11, Chandos Street, W.—Mon., 2.30 p.m., F.R.C.S. Course in Neurological Surgery. Lecture-demonstrations: (1) Intracranial Tumours, General; (2) Cerebral Tumours.

DIARY OF SOCIETIES AND LECTURES

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Demonstration. *Mon.*, 3 p.m., Surgeon Rear-Admiral Cecil P. G. Wakeley, Tumours of the Alimentary Tract; *Tues.*, 3 p.m., Mr. R. Davies-Colley, Tumours of the Breast; *Fri.*, 3 p.m., Dr. A. J. E. Cave, The Innervation of the Body Wall.

ROYAL SOCIETY OF MEDICINE

Section of Proctology.—Wed., 2.30 p.m. Clinico-pathological meeting at St. Mark's Hospital, City Road, E.C. Demonstration by Dr. Cuthbert Dukes and Mr. H. T. R. Bussey: Venous Spread of Carcinoma of Rectum. Cases and specimens will be shown.

DAVYHULME MILITARY HOSPITAL MEDICAL SOCIETY.—*Thurs.*, 3 p.m. Discussion: "Effort Syndrome." To be opened by Prof. Crighton Bramwell. Medical men and women in any Services (including civilian) will be welcomed.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced: Stoney Stanton (Leicestershire); Loanhead (Midlothian); Leominster (Herefordshire). Applications to the Chief Inspector of Factories, Cleland House, Page Street, S.W.1, by March 11.

APPOINTMENTS

CROWTHER, J. W., M.B., Ch.B., Examining Factory Surgeon for the Stretton District (Cheshire).

METROPOLITAN BOROUGH OF STEPNEY.—*Temporary Assistant Medical Officers of Health*: Caroline Meade, M.B., B.S., D.P.H., and J. P. Crichton, L.R.C.P. & S.Ed., D.P.H.

BIRTHS, MARRIAGES, AND DEATHS

The charge for insertion announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

BIRTH

KAHAN.—On February 28, to Dr. Nest Kahan (*née* Thomas), wife of Dr. Alexander Kahan, a daughter.

A NEW TYPE OF TYPHOID AND PARATYPHOID VACCINE

BY

A. FELIX, D.Sc.

(From the Lister Institute and the Emergency Public Health Laboratory Service)

Anti-typhoid inoculation is one of the old-established immunizing procedures introduced in the relatively early days of the bacteriological era. The original method of making typhoid vaccine (Wright and Semple, 1897: Pfeiffer and Kolle, 1896) has survived essentially unchanged up to the present time, and the type of vaccine still employed most extensively consists of a suspension of bacterial bodies which have been killed by heat and preserved by the addition of phenol. A great number of different methods have been described, both before and after the war of 1914–18, with a view to increasing the immunizing power of the vaccine and reducing the unpleasant systemic reactions which follow the administration of typhoid vaccines of the ordinary type. Some of these modified vaccines were suspensions of bacterial bodies killed by various chemicals instead of by heat, others were bacteria sensitized by treatment with homologous immune serum, while still other modifications consisted of bacterial extracts prepared in a great variety of ways (for references see Gay, 1918; Fleming and Petrie, 1934). These numerous types of typhoid vaccine were, however, all abandoned, since none of them was found to be superior to the ordinary vaccine made by the simple and time-honoured method of heat-killing and phenol-preservation.

Practical advances in anti-typhoid immunization, long delayed, have recently been made in quick succession as a result of our newer knowledge of the antigenic structure of the typhoid bacillus and of the different significance of different antibodies. Of the two typhoid antigens that were first differentiated the somatic O antigen is an important immunizing agent, while the flagellar H antigen is not (Felix, 1924: Arkwright, 1927; Topley, 1929: Schütze, 1930). Arkwright (1927), in an admirable discussion of the Army Council Report of the Anti-typhoid Committee (1912), showed that its main conclusions with regard to the preparation of typhoid vaccine were accounted for by the fact that the committee concentrated its attention almost entirely on one test as an index of immunity—namely, the measurement of the agglutinins produced by the inoculation of rabbits and man. The only typhoid agglutinin that could be estimated at that time was, however, the H agglutinin, and it is now known that the corresponding antigen is of little, if any, importance in the production of immunity.

Grinnell (1932) showed that the mouse is a suitable experimental animal for virulence and protection tests with the typhoid bacillus, and that the Rawlings strain—the classical laboratory strain used for more than thirty years in the preparation of typhoid vaccine in this and many other countries—had lost its immunizing capacity, although the cultures still possessed most of the commonly accepted criteria of smoothness. Perry, Findlay, and Bensted (1933a, 1933b, 1934a, 1934b) demonstrated in numerous experiments on mice that the degree of protection afforded by a typhoid vaccine was closely related to the virulence of the culture employed in its preparation. These workers also succeeded in "rejuvenating" the old Rawlings strain. It is now generally recognized that smooth mouse-virulent cultures of the typhoid bacillus possess the two antigenic constituents known as the O and the Vi antigens and that these are the essential elements which determine the immunizing capacity of typhoid vaccines (Felix and Pitt, 1934).

The balance of evidence obtained from active and passive protection experiments in mice indicates that the Vi antigen is the more effective prophylactic agent. At the same time reports have accumulated from various parts of the world showing that strains of the typhoid bacillus when freshly recovered from the blood culture invariably contain the Vi antigen, which, however, is gradually lost on subculture on ordinary media (Craigie and Brandon, 1936; Bensted, 1937, 1940). Earlier reports on the isolation from the blood of typhoid patients of strains devoid of the Vi antigen—for instance, that published by Felix, Krikorian, and Reitler (1935)—were probably incorrect and resulted from inadequate methods of growing and testing the cultures. It seems justifiable, therefore, to assume that the prophylactic value of typhoid vaccines has been greatly increased in recent years by the employment of selected strains which are particularly rich in the Vi antigen.

The Case for Changing the Old Method of Making Typhoid Vaccine

Why, then, it will be asked, should a new type of typhoid vaccine be suggested? It is perhaps not out of place to quote here two remarks from Gay's (1918) excellent monograph on typhoid fever: "It may well be questioned why further modification of typhoid vaccine

should seem necessary in view of the extremely good protective results that have already been obtained in certain large groups of individuals. . . . The only answer to such questions is and must ever remain that theoretical considerations based on the understanding of underlying principles will ever precede all practical advances" (p. 163). There can be little doubt that present-day methods of anti-typhoid immunization do not yet afford protection of a degree comparable to the immunity acquired by recovery from the disease. Gay's remarks seem to be as much to the point now as they were at the time they were written, nearly a generation ago.

The available knowledge of the properties of the Vi antigen clearly indicates that it is a remarkably labile substance which suffers very considerable damage by the treatment to which it is subjected in the customary processes of making typhoid vaccine. Sera from rabbits or horses immunized with suspensions of Vi strains sterilized by heating to 58° C. or by 0.5% phenol contain either no Vi antibody or only negligible amounts of it. Such sera are much less effective in protecting mice against virulent O + Vi bacilli than are sera which have been prepared by immunization with living bacilli and contain demonstrable Vi antibody. Treatment with formalin, such as that employed in the preparation of Grasset's (1939) "endotoxoid" vaccine or the mixture of T.A.B. vaccine and tetanus toxoid suggested by Ramon (1939) and Maclean and Holt (1940), so alters the Vi antigen that the resulting antibody exhibits a peculiar "functional deficiency," which is characterized by a reduced power of promoting phagocytosis and of protecting mice passively against infection with virulent strains of the typhoid bacillus (Felix and Bhatnagar, 1935). On the other hand, alcohol-treated suspensions stimulate in the rabbit or the horse the production of a Vi antibody which possesses the full functional efficacy of the antibody induced by immunization with the "natural" Vi antigen in living Vi strains (Felix and Petrie, 1938).

When mice are actively immunized, instead of passively protected by the injection of immune serum, the results are entirely different. In mice, vaccines sterilized in different ways induce an active immunity against infection with a virulent strain so long as cultures containing the Vi antigen are employed in the preparation of the vaccine. Schütze (1936) compared ten different methods of sterilization, including the standard method of heating to 53° C. for seventy minutes with the subsequent addition of 0.5% phenol, and found all of them of equal value in the active immunization of mice. Other workers have recorded similar results, and active-protection tests in mice are now employed in most laboratories as the sole method of assessing the protective value of typhoid vaccines. The demonstration of circulating antibodies in a suitable animal or in man, by using the serum to passively immunize mice, is not generally held to indicate the real protective value of a vaccine, and most workers discard it as unnecessary, though this technique appears to me to be of fundamental importance. The position is reminiscent of that already referred to when, in the early days of typhoid vaccination, agglutination tests were used as the sole criterion of immunity response, to the exclusion of the other suggested tests which were more difficult to perform, such as the estimation of the lytic or opsonizing power of the serum, or protection tests in the guinea-pig.

It is recognized that active antibacterial immunity depends mainly on the increased power of the tissues to elaborate specific antibodies rapidly when infection occurs, and the titre of the circulating antibodies that is found in the individual animal or man before the stimulus of infection occurs is not a reliable measure of this power. To that extent it is probably correct to state that active antibacterial immunity is independent of circulating antibodies. It is, however, equally well established that both the increased cellular reactivity and the circulating antibody owe their existence to the specific stimulus of the same substance—namely, the specific bacterial antigen. Thus it is also correct to state that in order to induce good active immunity the vaccine used must contain the specific antigen in that form which most effectively stimulates the increase of both cellular reactivity and the circulating antibody. Recovery from the disease, it is known, produces both these signs of immunity response.

It has been mentioned already that the active immunity experiments in mice do not disclose those great differences in the antigenic value of various preparations of the Vi antigen which are so clearly demonstrated by using the serum of vaccinated rabbits or horses in passive-protection experiments with mice or even by *in vitro* laboratory tests. This may perhaps be due to the fact that the typhoid bacillus is not a natural pathogen of the mouse. The customary anti-immunity test in the mouse therefore does not represent a sufficiently sensitive method of testing different preparations of typhoid antigens, and certainly should not be accepted as the sole test. It is obvious that in comparative tests of this kind all available methods should be employed in order to detect how far the immunizing properties of the various vaccines have been preserved or impaired. At present the position seems to be unsatisfactory, since the greatest care is taken to include in the vaccine only cultures that are particularly rich in the Vi antigen but very little is done to ascertain that this substance is being preserved in its most efficient form.

Methods of Assaying the Protective Value of Different Types of Typhoid Vaccine

Three distinct methods are available for carrying out comparative tests of different types of typhoid vaccine, as follows: (1) Active immunization of mice. (2) Immunization of rabbits with a view to establishing: (*a*) whether circulating Vi and O antibodies are readily elaborated; (*b*) whether the Vi antibody produced possesses full functional efficacy or belongs to the variety which is deficient in opsonizing and protecting power. (3) Tests of the Vi and O antibody responses in man.

Technical details cannot be discussed here. The tests are essentially identical with those employed in the estimation of the potency of therapeutic anti-typhoid sera, and have been described in detail (Felix, 1938). A few remarks only need be made concerning the practical application of the various tests.

1. Active immunization of mice is the least sensitive test. A vaccine that has been found to be of low protective value in this test should be condemned, and need not be further examined.

2*a*. The antibody response in the rabbit is estimated by Vi and O agglutination tests. It has been shown, in work already referred to, that in sera prepared against living Vi bacilli the Vi agglutinin titre runs approximately parallel with the protective power against living virulent bacilli, while the O agglutinin titre in all sera that contain the O antibody runs, on the whole, parallel with the protective power against the toxic action of killed typhoid bacilli. Thus the two agglutinin titres provide a trustworthy measure of the protective activities of the two antibodies, and the complicated protection tests can be safely replaced by the relatively simple agglutination reaction.

2*b*. The functional efficacy of the Vi antibody is examined in passive-protection tests in mice or in phagocytosis experiments (Felix and Bhatnagar, 1935).

3. A vaccine that has successfully passed the tests specified under paragraphs 1 and 2 should be submitted to the final

test of its capacity to induce the formation of Vi and O agglutinins in man.

So far this more severe method of assaying the efficacy of typhoid vaccines by tests in the mouse, the rabbit, and man has not been adopted by the majority of the workers engaged in the preparation of typhoid and paratyphoid vaccines. Rainsford (1937, 1939) experimented with typhoid vaccines sterilized by silver nitrate or sodium merthiolate and tested them in the manner outlined here. His experiments, however, were interrupted by the outbreak of the war before reaching the final stage of testing the efficacy of the vaccines in the inoculated human subject.

Experiments with Alcohol-killed Typhoid Vaccine

As soon as it was found that alcohol-killed typhoid bacilli stimulated in the rabbit abundant Vi antibody of full protecting and opsonizing power (Felix and Pitt, 1936; Felix and Petrie, 1938) an experiment was arranged to test for antibody response to such vaccine in the inoculated human subject. With the kind co-operation of Dr. W. D. Nicol, medical superintendent of the Horton Mental Hospital, 50 female mental patients were given three doses of the vaccine by the subcutaneous route, and another group received large doses of the same vaccine by the mouth. Samples of blood were taken in each case before the first dose and again eighteen days after the third dose, and the sera were examined in parallel by agglutination tests, using as reagents the same batch of agglutinable suspensions. Any rise in agglutinin titre corresponding to an increase of 100% or more was taken as "significant." The results of the O and Vi agglutination tests are summarized in Table I.

TABLE I.—*Percentage of Cases showing a Significant Increase in O and Vi Agglutinins after Immunization with Alcohol-killed Typhoid Vaccine containing no Preservative*

	No. of Organisms in Dose	No. of Immunized Persons in Group	Percentage Frequencies of Significant Increase in Titres	
			O	Vi
Subcutaneous inoculation	1st dose, 2,000 × 10^6 2nd ,, 3,000 × 10^6 3rd ,, 3,000 × 10^6	50	93.0	43.0
Oral administration	1st dose, 60,000 × 10^6 2nd ,, 80,000 × 10^6 3rd ,, 80,000 × 10^6	44	31.9	4.5

It is seen from the table that the results obtained were very encouraging indeed, since the subcutaneous inoculation of the vaccine had induced a detectable rise in O antibodies in nearly all and of Vi antibodies in nearly half the inoculated. Though the doses were larger than those employed in the customary T.A.B. inoculation the reactions following the alcohol-killed vaccine seemed to be much less severe. The table also shows that the oral administration of very large amounts of the vaccine, which was given on the empty stomach in the form of a saline suspension without the addition of bile, only led to very feeble stimulation of either the O or the Vi antibody.

The vaccine used in this experiment did not contain any preservative. The bacilli were killed by treatment with 75% alcohol; the latter was then removed by centrifuging and washing with saline, and the bacillary bodies were made up to the required opacity with saline alone. However, re-examination of samples of this vaccine after storage for half a year in the cold room, in saline alone or with the addition of 0.5% phenol or 0.35% tricresol, gave the disappointing result that each of the samples had almost entirely lost the capacity of stimulating formation of Vi antibody in the rabbit, though O antibody invariably was produced to high titre. This alcohol-killed vaccine could therefore not be recommended for use in large-scale inoculations, since a vaccine must contain a preservative capable of protecting it from casual contamination. Freshly prepared alcohol-killed vaccine containing no preservative was, however, employed during the past few years for the immunization of those amongst the personnel of the Lister Institute who were often handling virulent typhoid bacilli, and the impression gained in the course of time was that the reactions following the inoculations were less severe than those produced by the customary heat-killed and phenol-preserved vaccine. The experiments referred to were not published, but were recorded in the Annual Report of the Lister Institute for 1937.

Alcohol as a Preservative of Typhoid Vaccine

During the present war experiments with the alcohol-killed vaccine were continued, and the suggestion was made by Prof. G. S. Wilson of the Emergency Public Health Laboratory, Oxford, that alcohol might serve not only for the sterilization of the vaccine but possibly also for its preservation. This suggestion was soon found to be most valuable.

Long experience of alcohol-killed suspensions of the typhoid bacillus had proved beyond any doubt that a solution containing 75% absolute alcohol and 25% normal saline was a most reliable bactericidal agent. Large quantities of typhoid vaccine sterilized in this way and suspended in saline had been employed during the past few years for the immunization of horses in the course of the preparation of therapeutic anti-typhoid serum (Felix and Petrie, 1938), and in no instance did sterility tests on the numerous batches of vaccine prepared disclose the survival of either typhoid bacilli or other organisms.

The disinfectant action of alcohol was now compared with that of 0.5% phenol, using *Staphylococcus aureus* as the test organism. The comparative tests, which need not be described here in detail, were conducted both in saline alone and in saline containing 2,500 millions of alcohol-killed T.A.B. bacteria per c.cm. The clear-cut result was that the disinfectant action on *Staph. aureus* of 25% alcohol was slightly stronger than that of 0.5% phenol, while that of 20% alcohol was slightly weaker.

Next the effect of the subcutaneous injection of saline containing 25 or 30% alcohol was tried out on me and on a few volunteers. The injections of 0.5 or 1 c.cm. of these solutions were felt as a sting lasting for a fraction of a minute, but did not cause any local or general reaction. It was therefore decided that 25 or 22.5% alcohol could be employed as a suitable preservative of typhoid vaccine.

Batches of T.A.B. and T.A.B.C.* vaccine were prepared for experiments in rabbits and for comparative trials in human subjects. Two different vaccines were made in each case, both equivalent in composition and total bacterial count to the customary T.A.B. or T.A.B.C. vaccine—i.e., 2,500 million organisms per c.cm.—but prepared by one of the following two methods: (*a*) sterilized by treatment with 75% alcohol and preserved in saline containing 25% alcohol; (*b*) sterilized by treatment with 75% alcohol, washed on the centrifuge with saline, and preserved in saline containing 0.5% phenol. At the same time a quantity of the alcohol-killed typhoid suspension that served as one of the components of the mixed vaccines was retained for further experiments in

* Under the Therapeutic Substances Regulations the denomination T.A.B.C. now signifies in this country a vaccine containing typhoid bacilli along with paratyphoid bacilli of Types A, B, and C, and not, as previously, a vaccine containing typhoid bacilli and paratyphoid bacilli of Types A and B plus the vibrio of cholera; this latter vaccine is now known as T.A.B. + cholera.

rabbits, divided into five equal portions, and suspended in: (1) saline, (2) saline + 0.5% phenol, (3) saline + 25% alcohol, (4) saline + 30% alcohol, and (5) saline + 50% alcohol. All the vaccines were stored in the cold room at 1° to 2° C. and were tested for antibody response in rabbits and in human subjects after various intervals of time. The comparative trials in man are described in a paper by Felix, Rainsford, and Stokes that will appear in the next issue of the *Journal*. The experiments in rabbits are summarized in Tables II and III.

TABLE II.—*Typhoid Vi Antibody Response in Rabbits Immunized with T.A.B. and T.A.B.C. Vaccines*

Vaccines Sterilized with Alcohol			No. of Rabbits in Group	No. of Rabbits Showing Significant Increase in Vi Agglutinin Titre				Average Vi Agglutinin Titre after First and Second Intravenous Injections
Batch	Stored at 1° to 2° C. for	Preserved with		After Subcutaneous Injection of		After Intravenous Injection of		
				0.5 c.cm.	1 c.cm.	1 c.cm.	2 c.cm.	
T.A.B.	4 months	Phenol	3	0	0	0	0	
		Alcohol	3	0	0	3	3	1 : 20
T.A.B.C.	1 month	Phenol	3	0	0	1	1	1 : 3
		Alcohol	3	0	0	2	2	1 : 7

Table II shows that one of the alcohol-killed vaccines that had been preserved with phenol failed to stimulate Vi agglutinin, while the other induced formation of Vi agglutinin in only one out of three rabbits, whereas the two alcohol-preserved vaccines did so in five out of six. It is seen from the table that Vi antibody was in no instance demonstrable after the two subcutaneous injections, but made its appearance only after intravenous injection of a dose identical with the maximum dose that is employed in the customary subcutaneous inoculation of adult men, making no allowance for the difference in body weight. This fact is noteworthy in view of the results—discussed in the subsequent paper—which were obtained in human subjects inoculated with these four batches of vaccine. On the other hand none of the twelve rabbits failed to show a significant rise in the typhoid O agglutinin even after the first subcutaneous dose. At each stage during the immunization of the rabbits the average typhoid O titres were much the same in the four groups—namely, about 1 in 500 after the first subcutaneous injection, about 1 in 1,000 after the second subcutaneous injection, and about 1 in 5,000 after the first intravenous injection. In this and the following experiment the rabbits were inoculated at weekly intervals and the samples of blood were taken on the seventh day following each immunizing injection. The degrees of agglutination that have been employed to indicate the O and Vi titres respectively were identical with those used in the examination of the sera from inoculated human subjects, and are defined in the subsequent paper.

TABLE III.—*Vi Antibody Response in Rabbits Immunized with Variously Preserved Typhoid Vaccines*

Alcohol-killed Typhoid Vaccine Stored for 9 Months at 1° to 2° C. Suspended in	No. of Rabbits in Group	No. of Rabbits Showing a Significant Increase in Vi Agglutinin Titre after Intravenous Injection of		Average Vi Agglutinin Titre after Intravenous Injection of	
		500 · 10^6 Organisms	1,000 · 10^6 Organisms	500 · 10^6 Organisms	1,000 · 10^6 Organisms
Saline	4	2	2	1 : 4	1 : 10
Saline + 0.5% phenol	4	1	1	1 : 2.5	1 : 2.5
Saline + 25% alcohol	4	4	4	1 : 20	1 : 80
Saline + 30% alcohol	4	4	4	1 : 10	1 : 50
Saline + 50% alcohol	4	4	4	1 : 35	1 : 90

Table III corroborates the observation, already referred to, that the capacity of the alcohol-killed vaccine to stimulate Vi antibody formation deteriorates on storage in saline with or without the addition of 0.5% phenol. At the same time the table clearly demonstrates that the presence of alcohol in the vaccine prevents this deterioration taking place for at least nine months, and probably for much longer. It is also seen that 25% alcohol seems to be as effective in this respect as the two higher concentrations tested, though the latter conclusion may have to be modified after observation over a longer period of time. Again, there was no significant difference in the O antibody response to the five different vaccines. Each of the twenty rabbits produced abundant O antibody, and the average titres in the five groups were of the same order—about 1 in 5,000 after the second dose of vaccine.

The Vi Antigens of Bact. paratyphosum A, B, and C

A few remarks must be made here on the other three constituents of the mixed typhoid and paratyphoid vaccine. Some time ago *Bact. paratyphosum* A and B were found to possess specific Vi antigens of their own (Felix and Pitt, 1936), while *Bact. paratyphosum* C contains a certain amount of the specific Vi antigen of the typhoid bacillus (Kauffmann, 1935). So far most workers have paid very little attention to these findings, because the presence of these antigens in cultures of paratyphoid A, B, and C bacilli has much less striking effects on their virulence, agglutinability, and immunizing properties than the typhoid Vi antigen has on the typhoid bacillus.

Experiments carried out in collaboration with Miss R. M. Pitt before the war, but not yet published, strongly suggest that the heat-labile somatic antigens of paratyphoid A and B bacilli have chemical properties essentially similar to those of the typhoid Vi antigen, though they differ from the latter in certain respects. These antigenic components must therefore be recognized as separate and distinct entities, quite different from the heat-stable somatic O antigens of paratyphoid A and B bacteria. In experiments on passive immunization of mice pure Vi serum has a powerful protective action against virulent paratyphoid B bacilli, and the same is probably the case with paratyphoid A bacilli, though experimental evidence on this point has not yet been published.

From this brief summary of the experimental data three conclusions of practical importance in the preparation of T.A.B. or T.A.B.C. vaccine seem to be quite obvious: (*a*) The cultures of paratyphoid A and B bacilli to be included in the vaccine should contain maximum amounts of both the O and the Vi antigen. (*b*) Treatment with alcohol, instead of with heat and phenol, is likely to enhance the protective power of the vaccine against infection with paratyphoid A or B bacilli, though the advantage may not be of the same magnitude as it is in the case of the typhoid bacillus, since heat-killed or phenolized suspensions of paratyphoid A or B bacilli do stimulate circulating Vi antibodies in the rabbit. (*c*) If, for special reasons, paratyphoid C bacteria also are included in the vaccine, further advantage is gained by selecting a strain which possesses the specific Vi antigen of the typhoid bacillus and by treating it with alcohol.

Technique employed for the Preparation of Alcohol-killed and Alcohol-preserved Vaccine

This technique is very simple indeed. The growth on plain agar from Roux bottles of the usual size is washed off with 20 c.cm. of sterile saline per Roux bottle, the suspensions are collected in flasks containing glass beads, and a count or estimation by opacity is made. The growth from one Roux bottle, 8½ in. by 4½ in., usually yields about 1,500,000 × 10^6 organisms of the typhoid

and paratyphoid strains employed, varying according to the quality of the agar medium. Absolute alcohol is added to the suspensions in the proportion of 60 c.cm. of absolute alcohol to 20 c.cm. of saline. The flasks, which now contain the bacterial suspensions in 75% alcohol, are kept for two days at room temperature in the dark and are repeatedly shaken during that time.

The time required for the sterilization of the suspensions is very short—probably to be measured in minutes rather than in hours—nevertheless it is advisable to prolong the treatment for forty-eight hours and to ensure very thorough shaking. It is well known that absolute alcohol is a very poor disinfectant, and it might be feared that some contaminants, especially spore-bearing organisms, might gain access to the suspensions with the alcohol. It has been mentioned already that treatment with 75% alcohol for forty-eight hours at room temperature has invariably accomplished sterilization of each batch of vaccine that has been prepared up to the present time, without previous sterilization of the commercial absolute alcohol.

On the morning of the second day of the treatment with 75% alcohol the supernatants are decanted or sucked off, and the sediments are resuspended in the same quantities of fresh 75% alcohol and allowed to stand for some hours, until the bacteria have settled down completely. The solution of 75% alcohol – 25% saline to be used for this purpose should be prepared at least two days in advance and kept at room temperature, to ensure sterilization of the commercial absolute alcohol. The second supernatants are then sucked off as completely as possible. This procedure removes from the suspensions most of the constituents, mainly broth, which may have been collected from the agar medium together with the bacterial growth.

The deposits now consist of about a tenth to a fifth of their volume of solid bacteria and the remaining part of 75% alcohol. The amount of alcohol present in the deposits is estimated approximately and an appropriate adjustment is made while the dilute alcohol is being prepared, so that the deposits are finally suspended in saline containing 22.5% alcohol. This dilute alcohol should be prepared from a stock dilution of 75% alcohol which has been stored at room temperature for not less than two days. The suspensions of the three or four strains that are to be incorporated in the vaccine are then tested for sterility and again counted by opacity or some other method, and the final product is made by mixing the calculated quantities of the various suspensions and further diluting with 22.5% alcohol.

Attention must be paid to the fact that suspensions of alcohol-killed typhoid or paratyphoid bacteria have an opacity considerably less than that of suspensions equivalent in number of bacteria but killed by heat and preserved with phenol. The difference in opacity is about 10 to 20%, and is accounted for partly by the destruction of the flagella and partly by some alteration in the physical condition of the surface of the bacteria.

The methods used for the selection of the most suitable strains and the preservation and maintenance of the cultures have been described in detail in previous papers. Freshly isolated strains of typhoid and paratyphoid bacilli are not necessarily the best source of the antigens that are essential in the make-up of a potent vaccine. Though many strains at the time of their isolation are highly virulent and possess the Vi antigen in maximum amount, only few have the ability to maintain it at a high level when subcultured on artificial media. The strains employed in the present experiments—*Bact. typhosum* strain Ty 2, *Bact. paratyphosum* A strain HA 6, *Bact. paratyphosum* B strain HB 3, *Bact. paratyphosum* C strain K 32 (Kauffmann)—are all known from earlier work, and the first three strains have been chosen for their outstanding ability to produce Vi antigen in maximum amount when grown on plain agar for periods of many years.

The routine examination of the cultures consists of agglutination tests alone, using pure O and pure Vi sera. Occasionally the precaution is taken to check the results by virulence tests in the mouse. Bensted (1937), who has had much experience of such tests, found that the estimation of the Vi content of typhoid cultures by agglutination tests was often a more accurate guide in observing slight differences in virulence than the actual mouse test itself, unless large numbers of animals were employed.

The important discovery made by Craigie and Yen (1938) of type-specific typhoid Vi phages also must be mentioned in connexion with the problem of selecting the typhoid strain or strains for inclusion in the vaccine. It is known that by means of these phages Craigie succeeded in dividing typhoid strains from different sources into a number of different types. In view of the striking stability of these phage types it was considered necessary to investigate whether serological differences could be detected in the Vi antigen of typhoid strains belonging to different phage types. The experiments included cross-agglutination and cross-absorption tests, and phagocytosis and passive-protection tests in mice, and were completed in collaboration with Miss R. M. Pitt before the war but are not yet published. No difference between the actions of homologous or heterologous phage-type sera could be disclosed by any of these methods, and it appears to be safe to continue employing a single strain of the typhoid bacillus for making typhoid vaccine.

Summary

Ordinary typhoid-paratyphoid vaccine killed by heat and preserved with phenol stimulates in the rabbit and in man only negligible amounts of demonstrable typhoid Vi antibody.

Alcohol-killed vaccine readily stimulates circulating typhoid Vi antibody when injected intravenously into the rabbit, and induces its formation in nearly 50% of human beings after subcutaneous inoculation. This Vi antibody possesses its full opsonizing and protecting power.

Alcohol-preserved vaccine still contains typhoid Vi antigen in its effective form after storage in the cold for at least nine months, and probably much longer.

The technique of the preparation of alcohol-killed and alcohol-preserved T.A.B.C. vaccine is described.

*From the Lister Institute, London**

In earlier papers by Korenchevsky and co-workers (1933–40) the manifold effects produced by sex hormones on the non-sex organs have been repeatedly emphasized on the basis of (1) the changes in weight of the organs of gonadectomized rats as compared with those of normal intact animals; (2) the changes in weight of the organs of rats injected with various sex hormones as compared with those of uninjected litter-mates. The microscopical changes produced in some of the non-sex organs of the rats described in these papers have been examined, and the literature on the subject reviewed in the case of adrenals of males and females (Hall and Korenchevsky, 1938b; Hall, 1940), liver of males (Hall and Korenchevsky, 1938a), and kidneys of both sexes (Korenchevsky and Ross, 1940).

In the present paper the weights of the liver and heart of 281 male and 503 female rats from all our experiments, published and unpublished, have been divided into three series according to age and duration of hormone administration, and the data from each series have been pooled and statistically analysed. The other methods of examination of the organs are given below. In the experiments on females special attention has been paid to two male hormones, androsterone and transdehydroandrosterone, since both are naturally present in the female organism (Callow, 1936; Callow and Callow, 1938); and in the experiments on males to the effects of oestrogens, since large quantities of oestrone have been found in male urine (Häussler, 1934; Deulofeu and Ferrari, 1934, 1935; Zondek, 1934; Cartland, Meyer, Miller, and Rutz, 1935; Girard, 1938), and oestrone and oestradiol have been isolated in the pure form and in large quantities from the testes (Beall, 1940).

Technique

The general technique has been described in previous papers. The male rats have been grouped as follows: Series I and II (Table I) include experiments of 20 to 24 days' (in most cases 21 days') duration on rats aged 71 to 100 days (Series I) and 101 to 150 days (Series II). Series III refers to rats 137 to 177 days old injected with sex hormones for a longer period, varying from two to four, mostly three, months. Series I to III of the experiments on female rats (Table II) correspond in length of treatment to those on males, but the ages of the animals were 60 to 85 days (Series I), 86 to 125 (Series II), and 110 to 214 days, mostly about 150 days (Series III). The following hormones were used in the doses stated (mg. per week):

	Series I and II	Series III
Male Hormones		
Androsterone	6.3–25.2	7.5
Androstanediol	2.45–25.2	—
Transdehydroandrosterone	7.0–28.0	7.5
Testosterone pure	1.17–10.5	0.75–7.5
Testosterone P (propionate)	1.17–10.5	0.75–7.5
Testosterone D (dipropionate)	1.05–10.5	7.5
Δ^4-androstenedione	3.5–21.0	—
Female Hormones		
Oestrone	0.014–0.024	—
Oestradiol D (dipropionate) or BB (3-benzoate-17-n-butyrate)	0.018–0.09	0.018–0.2

In the tables a particular male or female hormone or a special dose is noted only when this hormone or dose had a considerably different effect on the liver or heart; the doses given in the tables are in mg. per week.

Sections were stained with haematoxylin and eosin and, when necessary, Masson's trichromic stain and scharlach red, and the usual microscopical investigation was made. In addition, in order to compare the size of the liver cells, the same technique of counting the number of cells in an area of known size with the aid of a camera lucida was used as in our previous paper (Hall and Korenchevsky, 1938a). In the present paper the cells were counted at a lower magnification than in the previous one; in this way a larger number of cells were contained in the measured area, which, it was felt, would lead to greater accuracy in the results. In Series I and II, Table I, the data for the number of cells are taken from our previous paper and multiplied by 2 in order to make them comparable to the figures of Series III.

In order to measure the heart-muscle fibres a technique was used similar to that described in our paper on kidneys (Korenchevsky and Ross, 1940). Longitudinal fibres were outlined on a measured area of paper (7.5 × 12.5 cm.), which had been previously weighed; the intermuscular spaces were then cut away, and the paper replicas of the fibres thus obtained were weighed. This weight was corrected to a standard weight of the paper, since different sheets and even different parts of the same sheet were found to vary in weight. Five areas from each heart were drawn and weighed in this way, and the average obtained represented the measurement of the muscle fibres. These measurements of liver cells were made in about a half, and of heart fibres in about one-third, of the total number of rats.

The technique used on the isolated hearts of rats will be described in detail elsewhere.

Statistical Treatment of the Results.—The data presented in the tables which follow were analysed by one of us (J. Cohen) by means of Fisher's t-test (Fisher, 1936). For the sake of simplicity the statistical significance (abbreviated "S.S.") is briefly given in the appropriate places in brackets. Thus "(S.S. 1:100)," for example, means that the observed difference between the means of two groups could occur by chance less than once in 100 such experiments. Not all the differences attain the same level of significance. The majority by far would have occurred less than once in 100 cases in random sampling. Many, however, would have occurred less than once in 1,000 or even 5,000 cases. All the instances where the statistical significance reaches or exceeds the level of 1 per 1,000 (by chance) are expressed as "S.S. 1:1,000."

Changes in Body Weight and Fat Deposition.—These changes are given in Tables I and II. They will not be discussed in detail here, but as they might have a considerable effect on the changes in weight and size of the organs they will be referred to, when necessary, in order to understand the mechanism of the weight changes in the liver and heart.

Effect of Gonadectomy

It is necessary to remember that in general, as compared with normal controls, castrated rats become lighter (S.S. 1:100) and ovariectomized rats heavier (S.S. 1:100–1,000), the changes usually becoming most clear during the later periods after gonadectomy, when there is also a tendency in most animals to increased fat deposition.

The liver in males becomes lighter both in actual weight (S.S. 1:100–1,000) and per unit of body weight (S.S. 1:20–1,000), whereas in females only the latter weight decreases (Series II and III, S.S. 1:1,000), the actual weight remaining unchanged or even slightly increasing. It is

* Dr. Korenchevsky desires to express to Oxford University, to Prof. E. S. Goodrich, and to Prof. J. A. Gunn his own and the Lister Institute's gratitude for the kind hospitality extended to him and his co-workers in the Department of Zoology and Comparative Anatomy and the Nuffield Institute for Medical Research.

thus clear that in males castration has a depressing effect on the development of the liver. There are, however, no great histological changes in the liver in either sex. The size of the cells is unchanged or (Series III) only slightly decreased In several cases there is an increase, sometimes considerable, in the vacuolation of the cells and the content of lipoid granules.

Similar changes occur in the weight of the *heart*, but they are much less pronounced: in males the actual weight becomes significantly smaller (S.S. 1:100), in females only the relative weight (S.S. 1:1,000, in the later periods after ovariectomy). Histologically no definite changes in the structure of the heart were found, except, on the average, a slight decrease in the size of the muscle fibres in males.

Effect of Oestrogens

This was similar in both sexes. The depressing effect of oestrogens on growth and body weight has been shown by several workers, including ourselves, in our previous and present papers (in the present series S.S. 1:50–1,000 in experiments of short duration, 1:100 in those of long duration). In most cases there was also a depressing effect on fat deposition (S.S. 1:20–1,000).

The effect on the actual weight of the *liver* was not uniform or definite except with large doses injected for long periods (Table II, Group 12), in which case a considerable decrease in the actual weight of the liver (S.S. 1:1,000) was observed. It should be noted, however, that in all experiments with esters of oestradiol the relative weight was greater than that of control gonadectomized animals (S.S. 1:100–1,000), returning to or even exceeding the normal relative weight (Tables I and II). This fact suggests that oestrogens may in reality have a stimulating effect on the liver, which is produced in spite of, and is obscured by, the general depression of growth of the organism.

This stimulating effect on the liver was clearly demonstrated by the increase in both actual and relative weights of the organ (S.S. 1:100–1,000) and in size of the cells after administration of small doses of oestradiol esters with a rest interval of 10 to 52 days between the last injection and the date of killing (Table II, Group 13). This indicates that some of the toxic effects of oestrogens might be prevented by administering small doses of oestradiol esters with a mild action but prolonged activity.

This suggestion as to the stimulating effect of oestrogens appears to be contradicted by the results of the measurements of the liver cells, which in Groups 7 (Table I) and 7–12 (Table II) were slightly smaller in rats injected with oestrogens. When, however, sections of these livers were stained with scharlach red there was found to a great decrease in or disappearance of the lipoid droplets in the cells; this gives a very probable explanation of the discrepancy and of the cause of it, since disappearance of fat from the cells should result in a decrease in their size. In agreement with this is the fact that the livers of oestrogen-treated animals are always dark brown in colour, while those of normal and especially of gonadectomized control animals are much lighter. This appears to be due to the disappearance of fat from the cells in the former animals.

The effects of oestrogens on the weight of the *heart* in rats of both sexes are similar to those on the weight of the liver: while, as compared with gonadectomized controls, no constant or significant effect on the actual weight of the organ was noted, the relative weight was in most cases increased (S.S. 1:100–1,000). Measurement of the muscle fibres showed no significant change, nor were any other histological changes noted.

However, the presence of an increased amount of heart tissue per unit of body weight in oestrogen-treated animals might suggest, as in the case of the liver, a stimulating effect of oestrogens on the heart. In any case, in ovariectomized animals the relative weight of the heart, which in the gonadectomized uninjected controls was decreased, was restored by oestrogens to or above the normal level.

Effect of Male Hormones

In general the effects of the various compounds of male hormones on gonadectomized animals are similar, varying only in degree. They are shown more clearly in the experiments of longer duration, on which the conclusions are mainly based. For this reason, and for economy of space, the effects of the different male hormones are given separately in some of the longer experiments only (Series III).

Transdehydroandrosterone produces the weakest effect, testosterone propionate the strongest; androsterone, especially in females, possesses all the beneficial stimulating properties without producing in some organs (e.g., the uterus) pathological effects which appear after injections of testosterone propionate. Compared with gonadectomized control animals, (1) there was a decrease in body weight (S.S. 1:20–100) and fat deposition (S.S. 1:100) only with large doses of strong male hormones (testosterone propionate); (2) in both sexes androsterone and testosterone propionate produced hypertrophy both in actual and in relative weights of liver and heart. The hypertrophy was especially pronounced in the experiments of longer duration (S.S. 1:100–1,000 for liver, 1:100 for heart), but in most cases was significant even after a short period of injections in males (S.S. 1:100–1,000).

In comparing weights of heart and liver of gonadectomized injected rats with those of the intact uninjected controls (Group 1) an important difference between males and females appears: in males the weights of these organs were returned only to or towards normal (Table I); in females (Table II, Series III) they exceeded the normal level after injections of androsterone (S.S. 1:20–100) and testosterone propionate (S.S. 1:100). Thus, in gonadectomized females, as has already been described in the case of the weight of adrenals (Hall, 1940), the male hormones have also a *masculinizing effect* on the weights of liver and heart, which approach those of the males.

Histologically, in experiments of long duration androsterone and testosterone propionate, unlike oestrogens, produced slight hypertrophy of the liver cells in both sexes, when compared with gonadectomized uninjected controls, and of heart-muscle fibres in males. In females there appeared also to be a slight increase in the thickness of the muscle fibres with these hormones (Table II, Groups 16 and 19), but the difference in the figures was very small (paper replicas weighing 21 mg. in ovariectomized controls, against 23 to 24 mg. in the injected animals). Our rats were killed by bleeding and therefore the intermuscular spaces in the heart only very approximately can be considered to be occupied by blood vessels. When these spaces were compared as weighed paper replicas, the amount of vascular tissue was found in the case of males (Series III) to be as follows: castrated controls – 67 mg., and testosterone propionate – 75 mg. In females this difference did not appear. It appears, therefore, that the enlargement of the heart of males injected with male hormones can be explained by hypertrophy of muscular tissue, with probable hyperaemia and hypertrophy of vascular tissue. No other histological changes were found.

Effect of Male Hormones Injected Simultaneously with Oestrogens

When male hormones and oestrogens are injected simultaneously the effect of the latter dominates that of the former if large doses of oestrogens are used. Groups 14 in Table I and 24 in Table II provide good examples of this. Therefore all our statements made for oestrogens are valid also for the characterization of this action.

On the other hand, when the dose of oestrogens is comparatively small (up to 0.018 mg. per week in males—Table I, Group 13; and up to 0.09 mg. in females—Table II, Groups 22 and 23; compared respectively with Group 7 in Table I and Group 11 in Table II) the male hormones androsterone and esters of testosterone are able in most cases to neutralize some of the depressing effects of oestrogens on body growth (S.S. 1:100–1,000), liver (S.S. 1:20–1,000), and heart (S.S. 1:100).

It is necessary to emphasize one very important point—namely, that not only do the actual weights of the liver and heart in most cases exceed those of the control animals, but also the weights per unit of body weight. In females the relative weights of the heart exceed even those of the normal control animals (Groups 22 and 23 as compared with Group 3, S.S. 1:100–1,000). Therefore the addition of a small amount of oestrogens to the male hormones might in some cases (oestrogenic deficiency) increase the stimulating non-sexual properties of the male hormones, especially in females. From this point of view the natural occurrence of oestrogens in the organism, even of males, acquires a new significance in addition to their useful co-operative effect on the sex organs (see the literature and our own experiments on these organs in our previous papers, referred to below).

Effect of Male Hormones on the Isolated Heart of Castrated Rats (R. C. Burbank)

Several experiments were performed on the isolated heart of normal and castrated rats, and of castrated rats

* We are most grateful to Prof. C. Lovatt Evans for his criticism and advice to use statistical analysis for the results obtained.

injected with androsterone and testosterone propionate, in most cases for a prolonged period of two months. A detailed account of these experiments and of the technique employed will be published elsewhere. A preliminary statement is given here of the results obtained in 85 experiments on 46 male rats when the potential strength of the heart was measured in these three groups of rats. The measurements were made by attaching 10 and 15 gramme weights to the level pulled by the heart's contractions and tracing these contractions on a kymograph. The amplitude of the contractions was measured on the tracings and their number counted before and during the suspension of the weights, in both cases for a period of one minute. Woodworth's (1903, p. 228) quotient of the potential energy of the heart was used for expressing the results obtained, which have been statistically analysed by one of us (J. Cohen), using the same method as above.

These quotients of potential energy of the heart in the three groups of rats were as follows:

	Before Test	During Test
Control normal rats	81.3	73.5
Control castrated rats	71.9	60.0
Castrated rats injected with male hormones	78.2	81.7

A statistical analysis of the results obtained showed that during the "weight test" the hearts of the uninjected castrated control rats were weaker than either those of the uninjected normal controls (S.S. 1:50) or those of the castrated rats injected with male hormones (S.S. 1:100).

Thus the results on the isolated heart are in complete agreement with those obtained by weighing of the organs and their histological examination.

Summary and Conclusions

Experiments made with sex hormones on 281 male and 503 female rats are recorded, with the resulting effect on the weights and histological structure of liver and heart, and also on the isolated heart of 46 male rats.

Hepatotrophic and cardiotrophic properties are non-sexual effects of male hormones, especially of androsterone and testosterone propionate.

Taking into consideration also their nephrotrophic property, described in a previous paper, the male hormones in suitable doses might be considered as very important natural physiological stimulants of such vital organs as the liver, heart, and kidneys.

So far as it is permissible, from the results obtained on animals, to suggest a therapeutical application of sex hormones to human patients, it seems that androsterone and esters of testosterone should be tried clinically in suitable diseases of the liver, heart, and kidneys when a physiological stimulation of these organs is required.

We again emphasize the suggestion given in the paper on the clinical application of the sex hormones in kidney diseases that androsterone is preferable to the testosterone esters as a physiological stimulant of liver, heart, and kidneys in both sexes, since it produces only a weak effect on the male and female sex organs and is present naturally in both sexes. It is most inadvisable to stimulate the sex function in patients suffering from such grave diseases as those of the liver, heart, and kidneys.

There is also a possibility that small doses of some oestradiol esters with a prolonged and mild action (such as oestradiol benzoate-butyrate), administered with long intervals between the injections, may also be considered to produce stimulation of the liver, and perhaps of some other organs. Because of the toxicity of oestrogens in overdose, however, great caution is needed in their clinical application.

From this point of view, in cases of deficiency of oestrogens in the organism, the simultaneous administration of male hormones with oestrogens might be advantageous, since the former are able to neutralize to some extent the depressing and toxic effects of oestrogens.

Grants from the Medical Research Council and the Lister Institute have enabled us to carry out this work, and to them our thanks are due. We wish to express our gratitude to Messrs. Ciba Ltd., in particular to Dr. K. Miescher, for the supply of the hormones.

CHEMOTHERAPY AND CONSERVATISM IN ACUTE SUPPURATIVE OTITIS MEDIA

BY

J. B. JESSIMAN, M.D.

Honorary Physician, the General Hospital, Malvern; Physician, the Isolation Hospital, Malvern

In the past have appeared many substantiated reports of striking results from sulphanilamide therapy, both in simple otitis and in suppurative otitis following paracentesis. An attempt is here made to assess its value in cases in which surgical intervention seemed to be urgent, but in which, nevertheless, it was purposely avoided.

Case I

A boy aged 9 returned to school with the remains of what had been called a common cold. There had been, however, an outbreak of "sore throat" in his family at the same time. He felt quite fit, and had a normal pulse and temperature, the only positive finding on physical examination being a subacute pharyngitis, the pharynx having the appearance of that seen the day following exfoliation in a moderately severe attack of scarlet fever. Eight days later he had had earache in the night, and the right drum was acutely inflamed in the upper half, while the postero-inferior quadrant was bulging with a bluish-grey sero-sanguineous sac extending into and resting on the adjacent canal. The left drum was normal. The temperature was 99° F., the pulse 90. Treatment with sulphanilamide was started. The sac quickly shrivelled up, leaving minute "puffs of cotton-wool" or "small snow-flakes" over the bulged area; the inflammation rapidly subsided, and in four days the drum was normal. On the following day the left ear started to behave in a manner similar to the right, responding to the same treatment in the same time. Deafness was only slight, and was very temporary.

Case II

The patient, a boy aged 8, following a cold two days previously, complained of bilateral earache which lasted the

whole night. In the morning his pulse was 114 and his temperature 101° F., while his pharynx was mildly inflamed. In both ears Shrapnell's membrane was inflamed and brightly injected; the normal contour and landmarks were obscured, but there was bulging of both tympanic membranes, in the postero-inferior quadrants—the right bluish grey, the left pinkish red. There was no mastoid tenderness. Local treatment was not considered necessary. Sulphanilamide treatment was begun immediately. Next morning the temperature had dropped to 98.8° F. and the pulse to 90, and his earache had gone. The sac in the left ear had shrunk a little; that on the right was slightly larger, until in the evening the whole canal was obliterated. On the third day the sac had become very much smaller, having a shrunken crenated appearance rather like that of a piece of dirty crumpled blotting-paper. It was now a quarter its original size; the normal contour of the drum was returning, and the outline of the malleus was visible, with the tip of the handle as a white knob. On the fourth day the right drum had reached the crenated stage, and was then a dirty cream instead of the previous bluish grey. On the sixth day both drums were approaching normality, but there was still some definite loss of lustre, with some brown staining of those areas which had previously been brightly injected, while over all were a few radial wavy dilated vessels. Hearing (as tested by a 30-in. watch), which had been impaired on the second day to the extent of Right $-\frac{1}{2}$ in. and Left $-2\frac{1}{2}$ in., was now normal. The normal pearly lustre and the tone of the drums were not recaptured till the eleventh day.

Case III

This patient, a girl aged 5, complained of earache within a few hours of the onset of a head cold. In the morning the temperature was 101° F., in the evening 104° F. The left drum showed a reddish-cream bulge in the postero-inferior quadrant, with a small bluish-grey bulla between the processus brevis and the sac. The fan-shaped area of acute inflammation and redness of the upper half of the drum was present as usual. Sulphanilamide treatment was instituted. On the following day the bulging was less marked, but the right drum showed streaking of the handle, with general flushing of the whole membrane. The temperature had dropped to 102.6° F. On the third day the left had quieted considerably, while the right showed a well-defined fan-shaped area or an arc, 4-7 o'clock, dirty white in the morning, changing to a deeper grey-white in the evening. The temperature was now 100° F., the pulse 96. On the fourth day the white arc had enlarged irregularly; it had become yellow and bulging, and definitely overhung the canal, with a few dilated vessels over the bulge. The fifth day saw a slight increase of the bulge, but the temperature was still dropping. On the sixth day the bulging was very much less, while the colour was a faint yellow with some streaks remaining. On the ninth day the left drum was normal in appearance except for some lack of lustre over the area originally affected. The right was pinkish. On the fifteenth day both drums were normal. Deafness was not appreciable at any stage, either to the whispered word or to a watch test, but with a child of this age it is notoriously difficult to place reliance on the latter test.

Case IV

A boy aged 9 had had acute otitis following measles one year previously. He was seen one evening half an hour after the onset of acute earache. The temperature was 99° F., pulse 96; both Shrapnell's membranes were inflamed—the right with three blackish bullae in the antero-inferior quadrant, the left with streaking of the handle. Sulphanilamide treatment was started. On the next morning the right canal was completely occluded by a bag almost inky black in colour. The temperature was then 98° F., and the earache was less. At 5 p.m. there was a discharge of blackish thin sero-sanguineous fluid from the meatus, while the earache was gone. Gentle cleansing revealed a perforation in the postero-inferior quadrant, an acutely inflamed Shrapnell's membrane, and a sodden appearance of the rest of the drum and of the canal, on which lay a considerable amount of bleached desquamated epithelium. The temperature had risen to 100° F. For the following two days there was a clear watery discharge, very slight in amount, with an occasional throbbing or full feeling in the ear on movement. On the seventh day there was some redness of the posterior of the drum; on the ninth the normal landmarks had reappeared and the postero-inferior quadrant was like dirty crumpled blotting-paper with pinkish streaks in the folds. On the twelfth day the drum and the hearing, which had been diminished, were normal.

Case V

A girl aged 5, admitted to hospital on September 27 with a moderately severe attack of scarlet fever, developed earache on the evening of October 15 with a temperature of 100.6° F., and was put on sulphanilamide. Her progress up till then had been normal. Her left drum was bulging with yellowish-white pus. Next morning the earache had gone. By the 18th the bulging had disappeared; the drum was becoming normal, and was patterned with the usual wavy dilated vessels. On the 21st lustre and tone were returning; the wavy vessels were then only very thin brown streaks. On the 25th both drum and hearing were normal.

Case VI

A girl aged 12 was admitted to hospital with scarlet fever on October 16. Her throat was very red, oedematous, and angry, and she complained of severe earache. She was given sulphanilamide. Her temperature ran between 99.6° and 98° F. for two days, and then fell to 97–98° F., while her pulse dropped from 100 to 76. The earache persisted in modified degree for two days. On examination a blackish-grey sac lay on the canal up against a redly inflamed membrane whose landmarks were obscured. By the 18th the sac had shrivelled and become lobulated, while two small blebs had appeared at the lower end of the handle. By the 21st the sac had completely gone and the blebs had been replaced by two red spots. There still remained some deafness and occasional discomfort in the affected ear. Hearing was normal on the 26th and the drum normal on the 28th.

Case VII

A girl aged 7 was admitted to hospital with scarlet fever on November 3. She had a very red raspberry-tongue, was powdering on the face and body, and had patchy exfoliation on the chest. She appeared to be seriously ill, and was very deaf. Her temperature remained 101° F. for two days, then gradually fell until it was 97.6° F. on the fifth day, while the pulse dropped from 132 to 96. Treatment with sulphanilamide was started on admission. The left drum showed slight otitis media, while the right was bulging with pus, and a bead of this yellow-green pus, obviously thick and tenacious, had just burst through a small perforation in the postero-inferior quadrant. On the 4th the earache had gone, while the bead of pus had dried or had become inspissated, assuming a conical shape. On the 7th the bulging was gone. The area was now a deep brownish colour, while the conical bead appeared to have become softer and to have sagged somewhat, probably owing to leakage of a minute quantity of serum. On the 11th deafness as tested by a 30-in. watch had risen from *nil* at contact to 12 in., the antero-inferior quadrant was normal except for some fine streaking, Shrapnell's membrane was still moderately inflamed, but the processus brevis had regained its normal white appearance. Progress thereafter was rather slow; hearing was normal by the 19th and the drum normal on the 21st—that is, eighteen days from the onset.

Discussion

From the case histories all seven appear to be cases of acute suppurative otitis media due to haemolytic streptococcal infection, especially Case I. It may be questioned whether all were in fact "suppurative" otitis, or whether some of them may not have been "catarrhal" in type. Clinically, it is usual to divide otitis into the catarrhal and suppurative forms, but the distinction is largely one of degree. Mollison (1936) says that "fever, earache at night, deafness, and a variable degree of bulging and injection of the drum with obscuration of the usual landmarks are signs each strongly suggestive of suppurative otitis, present or impending, whereas in simple catarrhal

otitis the symptoms and signs are usually ill defined." Past experience with similar ear lesions treated by paracentesis convinces me that the present cases were very definitely suppurative in type. The sudden onset, the earache at night with bulging in a few short hours, deafness and pyrexia in all of them, actual rupture of the drum in two cases, and in three the development of "snowflakes" or "puffs of cotton-wool" due in all probability to localized massing of pus cells, scattered over the inside of the drum, strengthen this conviction.

It has been generally agreed that with a bulging drum, be it due either to acute catarrhal or to acute suppurative inflammation, abortive measures are neither adequate nor safe. Watson-Williams (1933), Graham-Brown (1936), and Colledge (1937), in the more recent literature, suggest that "immediate" incision of the drum is necessary. If sulphanilamide therapy is capable of favourably influencing otitis (acute infection of the middle ear) at both the earlier and the later stages (Horan and French, 1938) the same good results should be possible in the intermediate stage—that is, in cases of suppurative otitis with bulging in which rupture has not taken place. It was decided, therefore, with some trepidation, and not without some anxious moments later, to try the effect of sulphanilamide without resort to surgical measures. All cases were treated as of the same age group for purposes of dosage. 7½ grains of sulphanilamide (1 tablet) was given, crushed or to be chewed, every four hours for the first two days, the number of tablets being reduced on alternate days by one till the patient was receiving two tablets only on each of the last two days. That was the minimum dosage, but where the local ear signs were not clearing satisfactorily reduction of the number of tablets was delayed. The average total per case was 225 grains over an average of seven days.

To be able day by day to observe clearly the progress made, through a canal unblocked by the usual discharge of pus, to note the gradual diminution of the bulge, to see the normal landmarks return and the inflammation disappear as resolution became complete and normal lustre and function were restored within a few days, was a novel experience. No less pleasing was the appreciation of the fact that by avoiding surgical measures these children were escaping not only the mental and physical trauma inseparable from anaesthesia and surgical operation but the further danger of superadded infection. Even in Case IV, in which rupture of a sero-sanguineous sac took place within a few hours of the onset, probably from greater virulence of infection, the discharge quickly became clear and very small in amount, so that after the first few hours there was no interference with visualization of the drum. Case VII was probably the most spectacular in that the infection was completely arrested at the actual stage of rupture. The likelihood of spontaneous remission may be dismissed as all the cases had a sudden onset, and even in a case of simple catarrhal otitis Mollison (1936) believes that with a sudden onset there is little chance of resolution. How much truer must it be with a drum bulging with pus! With such a small number of cases controls were out of the question, but I may be permitted to compare, or rather to contrast, other children treated in the same way during the same epidemic, seen at a later stage when rupture of the drum had taken place and a discharge had existed for at least twenty-four hours. In those the discharge remained purulent, the average time taken for complete recovery being twenty-three days, whereas in the present series the average was eleven days. Even with so small a number the results were so outstanding as to suggest that, if seen early and sulphanilamide therapy is immediately instituted, conservatism may be practised with safety in cases of bulging in which rupture has not taken place, with a dropping temperature, disappearance of pain, diminution of deafness, lessening of the bulging, and a reasonably steady pulse.

Summary

Seven cases of acute suppurative otitis media with bulging of the drum, occurring in children and successfully treated without paracentesis, are described.

The treatment adopted was the early use of sulphanilamide in adequate dosage. No local treatment was considered necessary.

CYSTICERCOSIS EPILEPSY

BY

WILLIAM BLYTH, M.D., D.P.M., F.R.F.P.S.G.

Psychiatrist, Emergency Medical Service

The following case is of interest on account of the relative rarity of the condition and the unusual clinical features presented.

Case Report

A soldier aged 37 was admitted to the neuro-psychiatric wards of an emergency hospital on November 8, 1940, for observation on account of marked abnormalities of conduct. There was a history of his having wandered away from his post while on guard duty and being unable to give any satisfactory explanation of his conduct. The patient was of good physique and was the eldest of seven children, all of whom are alive and healthy. Childhood was normal and he had had *no illnesses*. He served his apprenticeship as an iron-moulder, and in 1923 joined the Army. In January, 1927, he was drafted abroad, and served in various districts of Northern India until December, 1933, when he was placed on the Army Reserve and returned to London. While in India he contracted sand-fly fever in 1929 and suffered from intestinal colic of unknown origin in 1931.

He remained healthy and in constant employment until October, 1934, when he awakened one morning with "cramp-like" pains in both arms and both legs, and was informed by his room-mate that he had been throwing his arms and legs about during the night. He attributed his symptoms to the effects of nightmare, and did not seek medical advice. In May, 1935, he was found lying on his bedroom floor one morning, and had no memory of what had happened. He sought medical advice, but does not seem to have received any treatment. In November, 1936, he had an attack of "mental confusion," which came on suddenly, but there is no history of loss of consciousness or of falling. He was treated at this time with 1 grain of luminal at night, but the diagnosis of epilepsy does not seem to have been established. He remained well, and was called up for service in September, 1939. In May, 1940, when in France, he felt a choking sensation while bending over his haversack, and then lost consciousness. On recovering, his arm muscles were painful, but his companions informed him that there had been no evidence of twitching and that his colour had remained pale. He returned from France in June and remained well until September, 1940; at this time, while on guard duty, he felt a choking sensation coming on, and left his post in order to sit down. He did not remember anything further until he wakened up in the guardroom and was informed that he had threatened an officer with violence. In view of his plea of loss of memory he was transferred to this hospital for observation and investigation.

On admission no abnormality was noted in his physical condition. Examination of the central nervous system was negative. His blood gave a negative reaction to Wassermann

and Kahn tests. The cerebrospinal fluid gave a negative Wassermann reaction, the Lange test was 0111000000, Fehling's test was negative, no increase in globulin was found, and there was one small lymphocyte per c.mm. In view of his history the possibility of epilepsy was considered, and it was decided to utilize pitressin after his water balance had been established as a diagnostic test. This was carried out on November 13, but beyond the onset of severe frontal headache and nausea no definite result was obtained. At this stage the possibility of cysticercosis infection was considered, and it was elicited that pork had been a fairly regular article of his diet while in India. On November 14 radiographic films of the skull, root of the neck, upper arms, forearms, thighs, and legs were taken as a routine measure. The standard of radiograph aimed at was that of ordinary exposure conditions for bone detail with a very slight under-exposure. Widespread evidence of cysticercosis infection was obtained. The degree of opacity in the various cysts was seen to be uniform, and indicated that the infection was probably of equal duration in all parts.

Discussion

As MacArthur has pointed out in his original article on the subject, the history itself—namely, in the absence of any evidence of a familial or personal epileptic taint, the onset of fits in an adult who is not suffering from neoplasm, syphilis, or the after-effects of head injury—may be suggestive. The history of residence in India increases the possibility of cysticercosis infection, although the absence of such a history does not necessarily rule out this possibility. In most cases the diagnosis is easily established if palpable cysts are present, since one of these may be excised under local anaesthesia and examined in detail. In the present case this was not possible, as the parasites had lodged deep in the muscles and so escaped detection by any other means than that of radiography. In the absence of palpable cysts no single series of examinations can be relied upon to exclude cysticercosis, and in doubtful cases it is advisable to keep suspected cases under observation, examining the body surfaces at regular intervals for the development of superficial cysts and performing regular radiographic examinations. Blood films are considered to be of little diagnostic value, since, although an eosinophilia may be present in the earlier stages when the embryos are active in the body, in the established condition the parasites have become walled off and exert little influence on the blood picture. The prognosis in this condition must be a matter of extreme difficulty, since during life there is no method of determining the number of cysticerci present in the body or of ascertaining their future behaviour, on which the prognosis depends.

Summary

A case of cysticercosis epilepsy presenting unusual clinical features is described.

Emphasis is laid on the importance of regarding every case of epilepsy occurring in a previously healthy adult who has lived for a period in the Tropics as a probable case of cysticercosis until it has been proved otherwise.

The value of radiographic investigation in this condition is demonstrated.

A negative radiograph of the skull is not considered to be of any significance, since well-marked calcification can be demonstrated in cysts of the soft tissues.

Calcification of the cysts is a relatively slow process, and the degenerative changes may be complete in the muscles at a time when the brain is unaffected.

The size of the cysts depends mainly on their age and situation. If in firm tissues, where they are subjected to equal pressure on all sides, they are small and rounded; while in the muscles, where the pressure is unequally distributed, they lie between the muscle fibres and are oval in shape.

Evidence is produced in support of the theory that the cysticerci while alive enjoy a relative tolerance on the part of the host, but that after death they act as foreign irritants and produce changes partly by their toxic effects and partly by increased pressure on the surrounding tissues.

My thanks are due to Lieut.-Colonel G. Petit and to Dr. A. M. Dryden for facilities in examining this case, and to Dr. J. Kemp Harper and Dr. J. Fergus Henderson for carrying out the radiological investigations.

CASE OF VENTRICULAR FISTULA

BY

NORMAN C. LAKE, M.D., M.S., D.Sc., F.R.C.S.

Senior Surgeon, Charing Cross Hospital

The recording of a solitary case can scarcely be expected to add much to our knowledge of the local effects of the newer chemotherapeutic agents, yet the following case presents some unusual features, justifying a very brief summary that includes only the essentials.

Case Report

A man was admitted to an E.M.S. hospital on June 1, 1940, having sustained a gunshot wound of the head an indefinite number of days previously. On account of cerebral compression he was unable to give any history, but it is known that he was not picked up until three days after receiving the wound. On admission there was a jagged septic wound of entry in the left parietal region, with foul discharge. The patient was semi-comatose and lay coiled up on his side. He had photophobia, right homonymous hemianopia, and weakness of the right leg, with up-going toe. A penetrating wound of the forearm, with compound fracture of radius and median nerve injury, was also found. The temperature was 99°, the pulse 56, and the respirations 18. Radiographs showed foreign bodies in the brain and a comminuted fracture of the left parietal. He was treated with 1 gramme of sulphapyridine (M & B 693) four-hourly, magnesium sulphate enemas, and intravenous sucrose injections.

On June 4 the scalp wound was excised and the opening in the skull enlarged, care being taken not to disturb any dural adhesions. The brain was black and mushy and foul-smelling. The track was explored for two inches, and portions of bone, metal, and hair were removed, together with much pus and broken-down brain. The longitudinal sinus was found plugged with septic clot; this was removed and the sinus packed with flavine gauze. A flavine pack was applied over the whole wound. Culture from the wound gave a profuse growth of organisms of the *B. coli* type. Post-operatively a fungating hernia cerebri developed; the track was explored with sinus forceps on several occasions, but only a small quantity of pus was obtained.

June 10.—Definite improvement. He was fully conscious, the pulse was 72, the fields of vision had improved, and the hernia was not increasing.

June 28.—For the past few days he had been getting worse again; the hernia cerebri was increasing and cerebrospinal fluid was escaping in large quantities from the centre of the hernia: evidently there was a fistula through to the lateral ventricle. Further treatment with sulphapyridine and hypertonics was given.

July 5.—The temperature was now 103°, and there was stiffness of the neck and pain in the back; large quantities of cerebrospinal fluid were still escaping, becoming slightly purulent. By lumbar puncture a heavy purulent fluid was obtained, practically pure pus, with very high cellular content, 95% polymorphs; cultures showed coliform organisms corresponding to those previously found in the brain; chlorides 0.665%,

protein 0.520%, no sugar. It is to be noted that the fluid was not under pressure, probably owing to the rapidly leaking fistula. Sulphapyridine was continued by injection, but no improvement was seen.

July 16.—Operation: the scalp was freed from edges of wound and freshened. Too much of the dura was missing to permit of closure; the edges of the sinus were cleaned up and the whole wound and fistula were packed with sulphapyridine powder; the skin edges were carefully approximated and closed watertight. Lumbar punctures and hypertonic treatment were continued.

July 24.—Considerable improvement: the wound healed by first intention. The cerebrospinal fluid was still cloudy—cells 910 per c.mm., polymorphs 95%, many pus cells present, cultures sterile; chlorides 0.710%, protein 0.185%, trace of sugar.

From this point progress was uninterrupted, and six months later the only remaining neurological signs were a right lower quadrantic hemianopia and a pulsating closed hernia cerebri of comparatively small dimensions. In the interval the divided median nerve had been sutured in the forearm, and now showed early signs of recovery.

Commentary

The special points to be noted in this case are: (1) The care taken to avoid meningeal infection in the first operation. (2) Despite intensive hypertonic treatment, the open hernia cerebri dragged upon the lateral ventricle and so led, after a time, to the formation of a fistula. (3) The fistula inevitably led to infection of the ventricles and then to spread to the basal and spinal meninges; it also produced profound alterations in the hydrodynamics of the cerebrospinal fluid, which accounts for the unusual features, such as the replacement of the fluid by frank pus under no increase of tension. (4) The failure of general chemotherapeutic treatment to arrest the widespread meningitis under these special circumstances; nevertheless the wound healed per primam although bathed in purulent cerebrospinal fluid. (5) After closure of the fistula the fluid had to pass through the foramina in the roof of the fourth ventricle and so dilute the spinal fluid, probably carrying to it sulphapyridine obtained from the wound and possibly some also from the blood stream.

Clinical Memoranda

Abscess of the Medulla Oblongata Associated with Chronic Pulmonary Tuberculosis

The unusual clinical features of the following case make it interesting enough to be placed on record.

CASE REPORT

On the evening of December 11, 1940, a police constable aged 43 was admitted to St. Thomas's Hospital, having been ill at his home for ten days. His health had previously been good, apart from a single attack of haematuria, for which he had been treated in 1933; and he had been on duty until the onset of his illness.

His original complaint had been of severe headache and aching in the back and limbs; he had also noticed some unsteadiness of gait. After three days vomiting started, and became increasingly troublesome. Four days before admission obstinate hiccup developed: he then noticed numbness of the right side of his face and of his right arm for the first time. He described the headaches as being confined to the frontal region. The onset of vomiting he associated with eating fish which he thought was not fresh. After vomiting had persisted for three days he found that it was getting increasingly difficult to swallow, and this difficulty was particularly noticeable when taking fluids. His appetite was good and he felt that he wanted to eat. He had had a chronic cough for some years, but during the last four days he had remarked that the cough had suddenly stopped. His bowels had been constipated since his illness and he had passed only small quantities of concentrated urine.

On examination he was markedly cyanosed and wasted; his temperature was 101.6°, pulse 52, and respirations 28. There was a fine nystagmus on looking both to the right and to the left. The disks were difficult to see, but appeared blurred at the edges. The tongue on protrusion deviated to the left. The speech was slurring. There was diminished sensation to pin-prick on the right side of the face and on the right arm. No other abnormality was found in the central nervous system. Examination of the chest showed poor air entry on both sides, more especially at the lung bases. He regurgitated fluids when given drink. When at rest he did not appear unduly distressed, but he became very dyspnoeic on slight exertion. His blood urea was 26 mg. per 100 c.cm., and the blood Wassermann reaction was negative. The cerebrospinal fluid showed: 12 cells per c.mm.; total protein 0.055%; a faint trace of globulin; and a negative Wassermann reaction. The fluid was not obviously under pressure.

A radiograph of the chest showed evidence of apical tuberculosis, more pronounced on the right side than on the left. The right base was emphysematous and the lower two-thirds of the left lung showed evidence of early bronchopneumonia. The patient was very dehydrated, and 5% glucose in saline was given by means of a slow intravenous drip; but he became distressed, so rectal glucose salines were substituted. His condition deteriorated rapidly, and the following day his speech was unintelligible. He showed signs of increasing pulmonary oedema and died during the afternoon.

A post-mortem examination was performed by Dr. J. A. R. Miles, who reported as follows:

> "Lungs.—A small spontaneous pneumothorax on the right side. Both lungs show apical tuberculosis, the right showing a number of small cavities. There was gross oedema of the bases of both lungs.
>
> Brain.—A small abscess about 0.5 cm. in diameter, situated centrally in the upper part of the medulla oblongata. There were no other significant abnormalities."

Death was due to the development of a septic abscess of the medulla oblongata following upon a chronic tuberculous infection of the lungs, which had become secondarily infected.

A film of the pus showed large numbers of Gram-positive cocci; tubercle bacilli were not found. Culture from the abscess was not done, as it was thought that it would give no further information of value, the infection being an impure one.

I am indebted to Sir Maurice Cassidy for his permission to give an account of this case.

H. BATHURST NORMAN, D.M., M.R.C.P.
St. Thomas's Hospital.

Perforated Oiled Silk in the Treatment of Burns

I am prompted to write this short note after reading the leading article in the *Journal* of November 16, 1940 (p. 672), and the report of the Royal Society of Medicine in the same issue (p. 679) on the treatment of war burns.

The present-day treatment of burns by tannic acid and gentian-violet, although giving excellent results as a rule, is not always satisfactory, particularly when sepsis occurs. The treatment of these septic areas is a problem, and in spite of all the various types of applications of lotions, oils, and even skin grafting, they often refuse to heal. The failure of epithelization is in my opinion due to too frequent dressings, which not only prevent healing and subject the patient to a daily torture, but even when carried out under an anaesthetic reduce him or her to a nervous wreck.

METHOD OF USE

Any treatment which produces this state of affairs is obviously wrong, and through the kindness of my colleagues

at the Liverpool Royal Infirmary I have had the opportunity of trying out the value of a partially occlusive dressing in the form of perforated oiled silk. It is applied as follows:

1. A simple zinc paste or ointment—e.g., ol. morrhuae et ung. zinci (*B.P.*) āā—is spread for a breadth of about half an inch on the surrounding sound skin reaching up to the edge of the burnt area.

2. A sheet of oiled silk, perforated with holes one-eighth of an inch in diameter and half an inch apart, is then cut to the size and shape of the burnt area, but with an overlap of half an inch to lie on the ointment margin. It is sterilized, preferably by boiling, and is spread out and placed direct on to the raw surface.

3. Dry gauze or a saline compress is put on the top of the oiled silk and the part is lightly bandaged.

4. This dressing should be left quite undisturbed, and changed entirely, twice a week only, when the margins of the burn are cleaned and the oiled silk is resterilized and replaced.

5. The gauze may be changed daily, but it is important that the raw area should be left untouched during the re-dressing.

6. As the part heals in from the edges the oiled silk should be trimmed to fit.

RESULTS

The improvement in the appearance of the wound (although, of course, this will vary according to its age) and in the general well-being of the patient is most pronounced in a few days. Gone are the terrors and horrors of the daily dressing, and, instead, cheerfulness and sound sleep return.

The rationale of the treatment is the protection given to the growing epithelium and the opportunity provided for it to proliferate, as it should, in its own serous discharge, without interference and without antiseptics. In the presence of the efficient drainage provided, the bactericidal action of the secretion from the wound is adequate to cope with any superficial infection, and there is consequently no septic absorption. Islets of epithelium rapidly appear, and capillaries develop so quickly in the healthy granulation tissue that their delicate walls are ruptured by the slightest injury or even, as in one case, under the influence of gravity. This patient had to be kept lying prone, as she was burned on the back of the thighs, and change of posture caused free bleeding in a few hours.

The healed skin resulting from this treatment, while not entirely devoid of thickened scar tissue, compares very favourably with the results of other mthods. The total number of cases treated is not large, but the burns have been extensive—in one case the areas measured 11 by 5 inches on the back of each thigh.

This method has also been tried in the primary dressing of a number of cases of small burns, with results which compare very favourably with those of other methods, and my experience leads me to suggest that further use might be made of it. It is not a new treatment for burns, and it is possible that perforated cellophane or some other non-adhesive material might be substituted for the oiled silk.

Liverpool, 1. R. STOPFORD-TAYLOR, F.R.C.S.Ed.

The February issue of *Industrial Welfare and Personnel Management*, the journal of the Industrial Welfare Society (14, Hobart Place, S.W.1), contains an article on hours of work which enforces the point that by undermining health long hours of work lower both quality and quantity of output. Striking evidence of the futility of overtime is shown in figures from an engineering firm: In January–June, 1940, 26,200 more overtime hours worked than in previous year; but also 23,800 more hours of absence; net addition only 2,400 working hours. Three-shift systems are generally recognized as making the best use of men and machines, "as machines can be used quite continuously, while workers are on duty for only eight hours a day and forty to fifty hours a week." It is not always possible, however, to obtain the necessary labour, and various alternative arrangements of hours are described in some detail.

Reviews

FRACTURES

Fractures. By George Perkins. M.Ch., F.R.C.S., Assistant Orthopaedic Surgeon to St. Thomas's Hospital. (Pp. 384; illustrated. 20s. net.) London: Oxford University Press. 1940.

There are certain well-known medical synopses which have long been popular, though chiefly for examination purposes. This book on fractures is a cross between a synopsis and an ordinary textbook. There is no preface, no introduction or references, and one finds throughout a dogmatism and an apparent objectivity that would lead the innocent reader to suppose that in the treatment of fractures the last word has been spoken. Actually the teaching is Mr. Perkins's own, and is in fact no more impersonal than the collections of lectures which from time to time have been brought together and published by other distinguished teachers in medicine and surgery. It is therefore a little unfortunate that in dealing with a subject in which man-made methods of treatment vary so much, each in the hands of its advocates yielding fairly good results, so able a teacher as Mr. Perkins should adopt a pontifical style. It also makes it easier for critics to find holes in his work, particularly where he is dealing with topics that are not usually regarded as within the province of the orthopaedic surgeon. For example, fractures of the skull are described in a manner so sketchy as to be quite useless; nor is it quite so easy as he suggests to reduce fractures of the nasal bones. His description of the treatment of open fracture is inadequate; the last few months have taught us that in compound fractures shock cannot always be disregarded, and we have come to be much more precise in the technique of excision of an infected wound. Yet the only thing that Mr. Perkins has to say about the skin incision is that one should not enlarge the wound more than is necessary: poor counsel for a worried resident surgical officer who wants to know how big the incision should be—*in other words, what is necessary.*

But having drawn attention first to these blemishes we can more easily commend all that remains. There are about this book, particularly in the introductory chapters, a clarity and precision that compensate for the somewhat jerky style. If a small allowance is made for the fact that the author is an advocate of under-treatment rather than over-treatment, of less rather than more splinting, it is fair to say that the man who follows his instructions will not often go wrong. The value of active movements from the earliest possible moment, and the dependence of functional recovery on the patient's interest in and use of the damaged part, could not be more clearly stated. It is possible that some will be a little nervous about the light-hearted way in which fractures of the lower end of the fibula, stellate fractures of the patella, and fractures of the shaft of the humerus are left to recover by natural means. Yet if the standard of simplicity and absence of meddlesome intervention so characteristic of this book were to be seen in the fracture departments of our hospitals much suffering and disability would be avoided.

Something must be said about the arrangement of the pages. The illustrations are all diagrammatic, and though many of them are crude they are on the whole effective. But when the author has finished with one subject the letterpress stops even if it has covered only a quarter of a page. What is meant to fill these gaping voids: the

reader's notes? If they are not intended for any such purpose, then one can only conclude that there is more paper in the country than we thought.

PHYSICS OF THE ATOM

The World and the Atom. By C. Møller and Ebbe Rasmussen. Foreword by Prof. Niels Bohr. (Pp. 199. 10s. 6d. net.) London: George Allen and Unwin, Ltd.

There can be no doubt that to the scientist of the future the first half of this century will be marked down as the period in which the subject of atomic physics was born. Fifty years ago the suggestion that an atom had a complex structure would have been regarded with suspicion, while to-day we not only know an immense amount about that structure but we know many of its details with astonishing accuracy. We actually know the diameters and periods of the electron orbits with greater accuracy than we know the dimensions and orbits of the planets of our solar system, and from movement of these electrons we are able to unravel with absolute precision the vast complexity of the lines of the spectrum. Moreover, there is scarcely any scientific investigation of the present day which does not make use of atomic physics; it is the basis of wireless reception, it is fundamental in the development of *x* rays, and it is the whole secret of radium. Yet its comprehension involves physical concepts of the greatest difficulty, which can really only be fully explained by the most advanced and intricate mathematics.

The World and the Atom is an attempt, and a very successful attempt, to explain in non-mathematical language the essential physics of the atom as it has been revealed by the work of physicists of the last forty years. Beginning with a general statement of atomic structure, it enters at once upon a historical account of the work of Becquerel and Rutherford on radium, and shows how this gave the first insight into the structure of the atom, and it explains how this structure accounts for the production of spectra and of *x* rays. The next chapter deals in greater detail with the minute structure of the atom and describes how this has been investigated and how the whole of the elements have been classified and indexed. The remainder of the volume deals with the extremely difficult problem of the structure of the atomic nuclei and the revolutionary methods by which this has been investigated, and with some of the implications in cosmic physics that are involved.

The whole book forms the clearest possible account of atomic structure, and it deserves careful study by all those who are to make use of modern physical methods. Even those who are fortunate enough to possess a good mathematical equipment will find it well worth while to look at those subjects from a more popular aspect and to realize that the problems they have been accustomed to express in mathematical formulae can, at least in outline, be described in simple terms.

INTERRELATION OF ABDOMINAL DISEASES

Inter-relation of Abdominal Diseases. By Elemér Forrai, M.D.Budapest, L.R.C.P. With a foreword by Sir Arthur Hurst, D.M., F.R.C.P. (Pp. 168. 12s. 6d. net.) London: William Heinemann (Medical Books) Ltd. 1941.

The study of structure, whether normal or pathological, has always had to precede that of function. In the case of the alimentary tract this led in the past to an artificial separation in our conception of its various diseases. Of recent years that attitude has to some extent been modified by three factors: the recognition of the frequency with which dyspepsias are based on organic lesions on the right side of the abdomen; the importance attributed to viscero-motor reflexes; and the study of allergy. The stage was therefore well set for the appearance of Dr. Elemér Forrai's book on the interrelation of abdominal diseases. Starting with cholecystitis, he points out that dysfunction of the gall-bladder or biliary stasis may be due to inhibitory reflexes from chronically diseased portions of the digestive tract. The bacteriology of cholecystitis indicates, though the ways of infection are different, involvement of several abdominal organs and the unity of origin of their inflammatory changes. He then goes on to discuss appendicitis, calling attention to the way in which it may excite spasmodic hour-glass contraction of the stomach, and to the importance of achlorhydria in permitting infection of the alimentary tract lower down. We can understand that removal of the appendix alone is of little value if it is only one part of the pathologically changed intestine. Dr. Forrai adopts Craven Moore's conception of reflex dyspepsia from a lesion more or less remote from the stomach itself. The gastric symptoms which occur in connexion with such lesions may be due partly to visceral reflexes, but in the end gastritis will develop. He prefers to speak, therefore, of gastro-appendiculo-cholecystitis, and in support of his thesis that it is a hereditary familial disease gives a number of interesting family trees. The connexion between the liver and this combined disease is worked out in an interesting manner, in which stress is laid on the detoxicating influence of the liver, and the author maintains that all allergic manifestations are accompanied by hepatic insufficiency which diminishes its detoxicating power. Due importance is given to emotional factors in upsetting visceromotor reflexes which allow of disturbed secretions and unchecked infections. An interesting point, in view of recent work on hepatic damage in the severe forms of thyrotoxicosis, is the effect claimed for a damaged thyroid as a contribution to the allergic state.

Though marred by some tiresome reiterations and the not infrequent misspelling of the names of the authorities quoted, this is a thought-compelling book well worthy of attention. Sir Arthur Hurst, to whose teaching the author is evidently much beholden, contributes an appropriate and commendatory foreword.

MIND AS A DISCRETE ORGAN

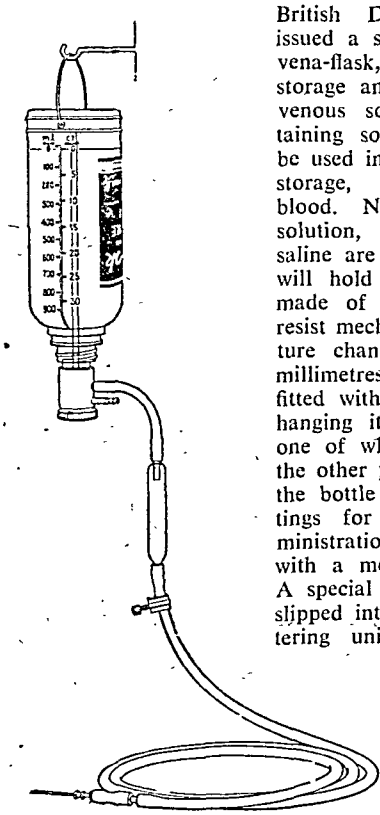
The Human Mind: The Organ of Thought in Function and Dysfunction. By Murdo Mackenzie, M.D., M.R.C.P. (Pp. 215. 7s. 6d. net.) London: J. and A. Churchill. 1940.

This small volume sets out a somewhat new approach to the problems of psychotherapy. Dr. Mackenzie looks on the mind of man as a discrete organ with a specific function, working in rhythm in space and time and driven by strictly mental forces. This notion, he suggests, is new and is elaborated for the first time in this book. To claim novelty for any opinion about the mind is somewhat bold. Something very like this approach has marked more than one ancient philosophy, but it has certainly not previously occurred to the psychology of the present age, with its unbalanced and incomplete "scientific" outlook. When the function of the mind is disturbed it is, according to Dr. Mackenzie's experience, accelerated in anxiety, retarded in apathy, or isolated from external contact in defence. In all these states, he says, it can be accurately observed. During and after readjustment the organ can be studied in the process of passing from faulty to full function, and the passage reveals that the same driving forces are present throughout. These are specific to the organ and their nature is strictly mental. Maladjustment of these forces is the common cause of nervousness and the resultant and widespread human suffering; readjustment restores hope, efficiency, and confidence. The future

of psychological medicine should, he considers, lie in the direct investigation and accurate description of the laws governing the mental organ.

Dr. Mackenzie has been a consistent champion of what Jung has called the "introvert"—the person who, from his relatively deliberate mental movement and narrow focus on life, has tended to be denied sufficient scope and the credit he deserves in a highly specialized and distracted world. The author is here chiefly concerned with the therapy of the depression which overtakes the "deliberate-simplifying" type of mind when it is thwarted by overmuch subjection to the current "immediate-amplificatory" methods of thought. There is nothing strikingly novel either in his clinical description of the problems of this kind of patient or in the lines of treatment he advocates, but his essay is likely to throw valuable fresh light for clinical psychologists upon syndromes which, when approached in certain ways that are now current, remain unintelligible and intractable. His stressing of the conflict of the opposites as a normal state of the healthy human mind is valuable; neglect of this fundamental fact is responsible for a good deal of the ineffectiveness of modern psychotherapy. He also includes some interesting deductions about the war and its psychological background. He has made a distinct individual contribution to practical psychology, and one which its practitioners would do well not to ignore.

Notes on Books



A little slip of a book, *The New M.O.*, was recently sent to the writer of this note for comments. It is a small pamphlet of twenty pages, written for medical officers attached to A.A. units by Colonel C. A. WEBSTER, T.D. The value of the little book varies inversely as its size; it is crammed full of sound, practical advice; it is worthy of study and application by all Army M.O.s. "The M.O. who is imbued with the idea he is to be 100% doctor will not be a *persona grata* with his C.O." "Your liaison with the regiment must be a happy contribution of social and business contact." Helpful detailed hints on the thousand and one duties of the M.O. are clearly and concisely given. Prevention of illness and preservation of health are ideals which it is possible to carry out in the Army, and which one day will also be practicable in civil life. Colonel Webster is to be congratulated on his effort. The book is printed for circulation in his Division only. It should be made available for all medical officers.

JULIUS SIGURJONSSON'S little book, *Studies on the Human Thyroid in Iceland*, is one which may be read with interest by all students of the thyroid gland. In it are presented the results of a study of the size, weight, iodine content, and structure of the gland in the general population of Iceland. His own data are compared with statistics from other regions and their significance is well discussed. It is shown that the weight of the thyroid is unusually low in Iceland, as it is also in Japan, Bergen, and Aberdeen. In an interesting chapter on hyperplasia the author produces evidence to support his view that the usual stimulus to thyroid hyperplasia is rather a low total iodine content of the gland than a low iodine concentration per gramme, as has been suggested by Marine. Neither in this chapter nor in a subsequent one on nodule formation is any mention made of hyperthyroidism in Iceland. It would have been interesting to see comparative figures of its frequency here and elsewhere. The book is priced at 6s. and is obtainable from H. K. Lewis and Co.

Those who had the pleasure of hearing Dr. RUSSELL L. HADEN lecture in England a few years ago will not be surprised that his *Principles of Hematology* shows the same free use of diagrammatic representation (second edition, Henry Kimpton, 21s.). The student who uses this book will learn a great deal about the manufacture and function of the blood cells and will be equipped with a useful discipline for facing clinical problems. He will learn very little about the natural history and morbid anatomy of diseases of the blood. The physiological approach to clinical medicine is indeed beset with great difficulties, if only because of the narrow limits of our knowledge. The student might well begin with Russell Haden's book, but he should proceed to Janet Vaughan's *Anaemias*, Claude Forkner's *Leukaemia*, and the Rose Research on Lymphadenoma if he really wishes to learn the principles of haematology.

Preparations and Appliances

THE VENA-FLASK

British Drug Houses has lately issued a special type of flask, "the vena-flask," fitted for both the storage and administration of intravenous solutions. The flask containing sodium citrate solution can be used in addition for the removal, storage, and administration of blood. Normal saline, 5% dextrose solution, dextrose saline, and gum saline are also available. The flask will hold one litre of fluid; it is made of glass specially treated to resist mechanical shock and temperature changes, and is graduated in millimetres and fluid ounces. It is fitted with a rustless metal ring for hanging it up and with two caps, one of which acts as a seal, while the other protects the whole neck of the bottle from contamination. Fittings for the collection and administration of fluid are provided with a metal screw-cap adjustment. A special metal gauze filter can be slipped into position on an administering unit when blood is being given. The principle of the apparatus is similar to that of the Medical Research Council transfusion outfit, though more elaborate in detail.

VARIOSTAB

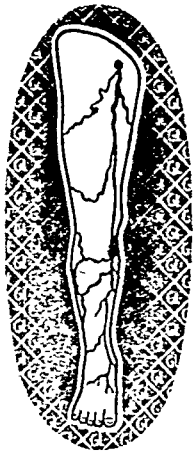
Variostab (Boots Pure Drug Co. Ltd.) is a preparation of ethanolamine oleate for the treatment of varicose veins. Ethanolamine oleate was reported on by Meyer (*Amer. J. Surg.*, 1939, **40**, 628), who found that it was as effective as sodium morrhuate and was superior to the latter preparation in that it did not provoke occasional allergic responses. Rogers (*British Medical Journal*, 1939, **2**, 383) considered ethanolamine oleate to be the most satisfactory of the sclerosing agents.

ALLANTOIN

It is becoming increasingly difficult to obtain synthetic compounds that are in any way out of the usual, and hence we welcome the announcement by Genatosan Ltd. that they are undertaking the production of a variety of fine chemicals. Among these allantoin is of particular interest. Two independent and somewhat unusual lines of research—namely, the study of the reputed healing action of comfrey root and the maggot therapy of wounds—both led to the conclusion that allantoin was the active agent, and that it caused leucocytosis and acceleration of wound healing. The latter is an action that is difficult to measure accurately, but the evidence available suggests that allantoin has a beneficial effect on the healing of septic wounds and ulcers.

To stand behind all diets

½ lb. and 1 lb. cartons



In the task of nourishing and protecting the nation, Farex *can* play a valuable part. Farex embodies in a single digestible food protective vitamins and minerals which otherwise could only be secured in an expertly chosen and varied diet. Farex is composed of wheat-flour, wheat-germ, oatmeal and maize, with *added* minerals and vitamins A, B and D. As befits a 'staple food,' Farex provides an abundance of carbohydrate; but the high percentage of protein (15%) and the presence of iron, calcium and phosphorus, and vitamins A, B and D, lift it right away from the usual run of 'health cereals.' As a weaning and invalid food Farex has been used successfully for years. But now, when national good health is a national armament, it cannot be too strongly emphasised that Farex is equally valuable as a daily nutritional safeguard to stand behind *all* diets, for all ages and conditions of people. Farex is ready-cooked, prepared in a few moments, and can be flavoured to personal taste. In emergency, Farex alone will maintain the nutrition of the individual longer than any other single food available

FAREX

PRODUCT OF THE GLAXO LABORATORIES

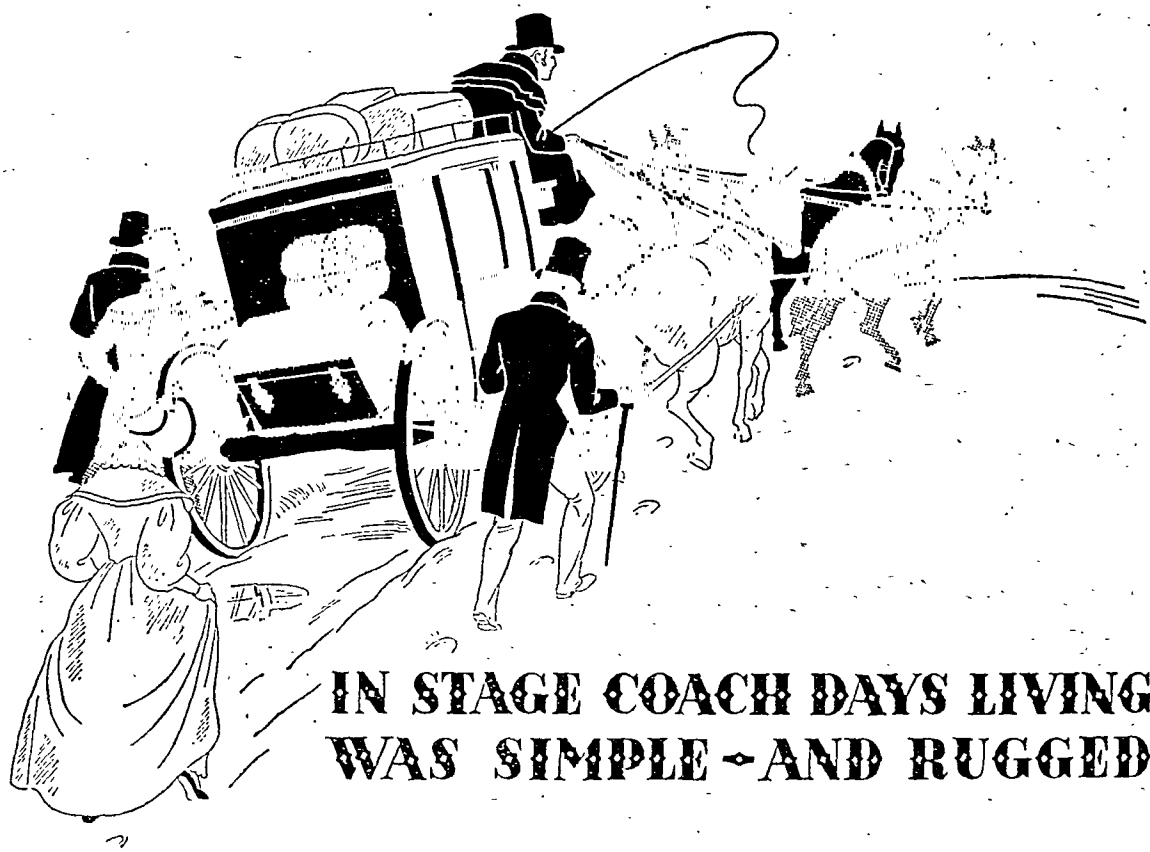
GLAXO LABORATORIES LTD. GREENFORD MIDDLESEX. BYRon 3434

Sclerosing agent of 6 marked advantages

An aqueous solution of ethanolamine oleate (5%) with 2% benzyl alcohol. Ampoules, 6 x 2 cc. Bottles of 15 cc. and 30 cc.

Designed to bring a greatly increased measure of safety and certainty to the injection treatment of varicose veins, the Glaxo product Ethamolin has proved its effectiveness both in trials and in extensive practice.

Briefly the advantages of Ethamolin are that it • gives a firm, adherent thrombus • contains no impurities • does not cause sloughing, even if leakage occurs • does not cause muscular cramp on injection • is constant in potency, which is retained indefinitely • is available at extremely reasonable cost.



Ethamolin thus virtually eliminates the disadvantages which were formerly liable to attend vein treatment, and provides every practitioner with the means of undertaking the injections with confidence of safety and success.

IN STAGE COACH DAYS LIVING WAS SIMPLE - AND RUGGED

But pain, a fairly constant factor in life, meant suffering then even as today. Many a dour disposition found its source in haemorrhoids . . . making a stoic of the sufferer . . . who found little joy in living.

Today, pain and discomfort resulting from haemorrhoids may be safely and efficiently relieved by Anusol brand Haemorrhoidal Suppositories.

These Suppositories relieve inflammation and congestion without the use of narcotic, analgesic or local anaesthetic drugs. They control bleeding and make evacuation easy and painless. Anusol is also available in Ointment form.

ANUSOL Haemorrhoidal Suppositories

FIRST AID FOR FIRST AID

One of the virtues of war is that it compels us to review old ideas and customs in a new light, especially when they relate to activities that have an urgent bearing on the war situation. One example of this is the renewed interest in and research on air-borne and droplet infections. Another is first-aid treatment of the wounded and sick, which, with the bombardment of our cities, is now a problem of the first importance. As our correspondence columns have shown, medical men are beginning to question the adequacy of long-established training methods in first-aid technique. Perhaps the main burden of the criticism has been that in peacetime first-aid instruction and manuals were directed too exclusively to the examiner rather than to the examinee. That is to say, the passing of an examination was something that loomed large in the minds of both teacher and taught, and not enough stress was laid upon the limitation of what a first-aider could do and how he should do it. Excellent as the teaching was, and however enthusiastic and intelligent was the first-aider, the victim of an accident ran the risk of delay in receiving expert medical treatment because of the desire of the first-aider to carry out to the last letter the elaborate details of bandaging and splinting which had been drilled into him. By the time the victim arrived at a hospital or doctor's surgery it was too often found that there was much to undo before proper and urgent treatment could be applied.

In making these criticisms we would not be thought to underestimate the magnificent work that has been done by the British Red Cross and the St. John Ambulance. For their admirable and self-denying work no praise can be too high. But it was probably with such criticisms in mind that the Birmingham Joint Committee of the British Red Cross Society and the St. John Ambulance Brigade decided "to investigate and report upon the present methods of training first-aid workers," and for this purpose set up a special first-aid subcommittee, having among its personnel not only medical officers of the two organizations but several of Birmingham's leading surgeons, including university professors. The subcommittee came to the conclusion that the standard of training of first-aid party leaders is low and that there is no proper training system for lay instructors; that the rank and file of the first-aid services have been taught too much unnecessary and even harmful detail; and that the seriously injured man should be handled by the first-aid worker as little as possible and be transported to hospital within the minimum period of time. What is needed is that the first-aid worker should be taught a lot about a little, rather than a little about a lot, and that he should firmly grasp the fundamental principles of dealing with cases of shock, haemorrhage, and asphyxia, and worry himself less about the elaborate bandaging that so handsomely illustrates the first-aid manuals. The Birmingham Joint Committee, recognizing that the basis of intelligent and skilful treatment is sound training, and that inefficiency is often the result of bad teaching, has boldly recommended the institution of a civilian first-aid training school; but for the time being the scheme has unfortunately been turned down by headquarters in London. The idea is not to disappear, however, because the new Birmingham Accident Hospital, urged on no doubt by the committee's report, has decided to undertake the training of first-aid workers for industry, and, as will have been seen in our advertisement columns, one of the duties of the new clinical director will be to supervise first-aid training, a step so far without precedent in hospital policy.

It is proposed that the civilian first-aid training school—when it comes into being—shall be staffed by a whole-time commandant and four permanent instructors, and that lecturers and examiners should be chosen from a gradually widening panel of medical men and women. The committee has also had the wisdom to see that the instructor is in as much need of instruction as those who are to be taught. The teacher, in fact, has to be taught how to teach, and this will be an important function of the school. It is intended that students taking the course, which will last two weeks, should live in the school, and that in addition to this there shall be a part-time course of a minimum of eighty hours' duration for those who are unable to give their whole time to the work. There will be special courses for industry and special courses for nurses, and medical students will be offered facilities for seeing the work of the school, as they will be the future first-aid teachers. Criticism is levelled against the ease with which first-aid workers have hitherto acquired certificates of proficiency in first aid, and the committtee recognizes that a higher standard of proficiency should be demanded. Not only that, but the first-aid worker is not to be allowed to rest on his laurels and is to be re-examined every two years to see that he is still up to date in his knowledge and efficient in his practice.

While, no doubt, war conditions have fostered the ideas of reform now contemplated by the Birmingham committee, it is but a continuation of ideas which were in being before war broke out. In July, 1939, the British Medical Association issued a report on first aid in industry which put forward a number of important recommendations. The Birmingham committee, as would be expected, has a special interest in the need for adequate first-aid treatment of industrial workers; and that this interest should be shared by the country as a whole is demonstrated by the fact that during 1937 it was estimated that the total charge on industry in respect of industrial injuries was something like £13,000,000.

Here, then, is the beginning of a movement which we hope will be fostered and eventually taken up by

other big cities in the country. If prosecuted with the care and forethought given to it by the initiators it will go a long way towards minimizing and preventing the pain and disability arising from accidents of whatever kind, whether they occur in air raids, on the streets, or in factories.

BRITISH MOSQUITOES AND THEIR CONTROL

Up to recent years, when the importance of mosquitoes in tropical disease has led to a greater diffusion of knowledge about these insects than formerly, most people were under the impression that while there might be "gnats" there were no "mosquitoes" in this country. When, therefore, instances of "mosquito nuisance" were reported they were usually traced in the lay press to accidental introduction of these insects from abroad. In fact, not only are there many species of true British mosquitoes, but the individuals of these species are often sufficiently numerous and active in their blood-sucking propensities to become a nuisance or even a sanitary problem. Thus at certain seasons it may be impossible in the woodlands to rest or enjoy the scenery on account of the pertinacious and blood-thirsty attacks of some day-feeding species, reminiscent of the ubiquitous shade-loving *Stegomyia*, or, as it is now called, *Aëdes aegypti*, of the Tropics. Night-biting species, again, by their interference with sleep and irritating bites, in seaside places especially, are a serious problem to hotel keepers and others whose custom may thereby be affected. To the annoyance of the biting may be added the tendency of the bites to become septic with sometimes serious consequences. In addition the malaria-carrying *Anopheles* are in many parts of the country quite numerous, and even transmission of malaria in times like the present may be brought about where the necessary infection is provided by soldiers and others returning home from abroad. In a few restricted areas entirely indigenous cases of malaria have long been known to occur—a present-day aftermath of the once widely disseminated "ague." Such cases are fortunately very mild, are usually considered by the victims to be colds or chills, but are shown by blood examination to be of true malaria.

Altogether, therefore, it is a matter of some importance that reported instances of "mosquito nuisance," and especially any reported cases of locally arising malaria, have for many years been closely investigated by the Ministry of Health. The results of the large amount of practical information so gained have lately been summarized in an official memorandum under the authorship of Colonel J. A. Sinton, Adviser on Malaria to the Ministry of Health, and Mr. P. G. Shute, Assistant Malaria Officer.[1] After a brief review of the subject of malaria transmission and mosquito nuisance in this country the memorandum gives a complete list of the mosquitoes so far recorded from the British Isles, together with a brief but sufficient description of their habits, breeding places, and methods of control. Twenty-nine species are recorded—four anopheline and twenty-five culicine species—of which latter, however, eight are so rare or so seldom bite man that they may be considered unimportant as causes of public health problems in this country. Of the remaining culicines two belong to the genus *Culex*, eleven to *Aëdes*, three to *Theobaldia*, and one to *Taeniorrhynchus*, the last-named being noted as the most extraordinary of the British mosquitoes, as its larvae and pupae live entirely under water attached to the roots of aquatic vegetation, and so, unlike the larvae and pupae of other species, which must come to the surface to breathe, are very difficult to detect.

The two species *Culex pipiens* and *C. molestus*, which closely resemble each other in appearance, have only recently been recognized as distinct species—an important point, as it is extremely doubtful now whether the former species ever attacks man. The latter is probably the only mosquito which is troublesome in the centre of large towns. It is a most persistent biter, and where it is present in large numbers its bites probably cause a greater indoor nuisance to man than any of the other species of British mosquito. It bites only indoors; the mosquitoes biting in gardens and other places in the open are usually *Theobaldia* or *Aëdes* where they are not *Anopheles*. *Theobaldia* are very large mosquitoes, attacking boldly and giving a very troublesome bite. They are noticeable in many country places, but are especially responsible for mosquito nuisance in urban areas, breeding in water-butts, tins, and almost any collection of water. Their bite is more irritating and results in more swelling than that of any other British species. Most species of *Aëdes* breed in woodland pools. Some, however, breed in open ponds on heaths and commons, or in ditches; one is known to breed only in brackish water near the sea, though it may fly as far as five miles inland, thus recalling the "salt marsh" mosquitoes of some parts of America. This brackish-water species, *Aëdes detritus*, is noted as having been responsible for a greater number of cases of serious nuisance than any other of the British species.

The methods of control, as may be gathered from what has been said, depend very much on the species responsible. On this account much labour and material may be uselessly expended if due attention is not given to identification of the species and knowledge of its habits. Usually it is desirable in serious cases to obtain expert advice, and in a footnote to the memorandum it is said that, if application be made to the Ministry of Health, the local authority can usually obtain the assistance of an expert, who will make a mosquito survey and give free advice on the steps to be taken. The memorandum itself, however, under the heading of "Control" and in notes upon the different species, provides much useful information, including measures that can be taken against the adult mosquitoes as well as those against the larvae, and suitable repellents which can be rubbed on exposed parts of the body such as ankles, wrists, back of neck, and ears, to protect the individual against bites. Altogether this publication represents a most important summary of the whole situation, and should serve as a work of reference to all interested in British mosquitoes, whether from the point of view of natural history, of the public health, or of individuals who may experience mosquito nuisance in this country.

[1] *Measures for the Control of Mosquito Nuisances in Great Britain*, by Lieut.-Colonel J. A. Sinton and P. G. Shute. (Memo. 238, Med. H.M. Stationery Office. 6d.)

CLINICAL TRAINING FOR BRITISH STUDENTS IN AMERICA

In our Parliamentary Notes this week will be found the report of a statement by the Minister of Health in reply to Prof. A. V. Hill on facilities offered by the Rockefeller Foundation for British medical students to pursue clinical studies in medical schools in the United States and Canada. The Minister expressed warm appreciation of this sign of practical sympathy on the part of the Foundation and of the medical schools in America, and undertook to do all he could to further the scheme, which should strengthen the beneficial co-operation in medicine and public health between Britain and the United States and Canada. This welcome offer had its origin in a desire to help medical education in this country during a very difficult time, but it holds out wider possibilities for future and happier days. A strong committee has been formed (with Prof. J. S. B. Stopford of Manchester as chairman and Prof. H. R. Dean of Cambridge as vice-chairman) to select twenty-five to thirty students from among those nominated by the medical schools in Great Britain and Northern Ireland. By this means some of our most promising students will see, and take part in, the inner life and work of the best American schools and hospitals. We understand that the Rockefeller Foundation generously offers free tuition and maintenance on the other side of the Atlantic for a period of one year, which may be extended to two years. No one will be sent to take up a Rockefeller studentship without the approval of his own medical school, and provision will doubtless be made to ensure that a student does not lose ground by reason of his absence. Moreover, as the Minister of Health made plain in reply to a supplementary question by Sir Francis Fremantle, no student chosen for the purpose of continuing his clinical course in America should feel reluctant to leave this country during the war: he can, indeed, be encouraged to regard it as a duty to be undertaken in the national interest and in the cause of medical education. Not more than two of the British students will go to any one institution in the U.S.A. or Canada, and their allocation will be made by the British Committee, whose membership, in addition to Prof. Stopford and Prof. Dean, is as follows: Prof. Hugh Cairns, Mr. H. L. Eason, President of the General Medical Council, Prof. George Gask, Mr. G. F. Gibberd, Dr. A. M. H. Gray, Prof. A. V. Hill, Prof. J. W. McNee, Sir Walter Moberly, and Sir Franklin Sibly, with Mr. W. B. Brander, of the Universities Bureau of the British Empire, as secretary (c/o University College, Gower Street, London, W.C.1).

HOSPITAL WAR SUPPLIES

Hospitals which have been bombed, or find their stocks of clothing, comforts, ward and surgery supplies depleted by the needs of air-raid victims, are now getting much help through the British Red Cross, which is drawing for their benefit upon gifts from friends and workers in this country, the Dominions, and the United States. A small committee of hospital experts, aided by Thomas Cook and Son, has worked out a scheme for bulk distribution of these gifts to "key" hospitals, and these, in turn, are distributing to their sector hospitals. Thousands of cases are now being issued in bulk, or broken up and repacked in necessary quantities. They contain everything a hospital can require for use, from "helpless" shirts to surgical instruments for general and special use. Three thousand complete "bed sets" are coming to hand from the United States. Each consists of three blankets, twelve sheets, eighteen pillow-cases, with appropriate towels, buckets, pitchers, tumblers, even tooth-brushes. Water and instrument sterilizers, bandages and dressings, are also arriving. Bulk reception and distribution to "key" hospitals having been arranged, it now remains for local hospitals to make their applications to their key hospitals, and assist the latter in the sorting and distribution of supplies throughout their sectors.

SULPHATHIAZOLE AND SULPHADIAZINE

It is now becoming possible to assess the value of sulphathiazole in relation to other sulphonamide compounds. An outstanding original claim for this drug was its superior action on staphylococcal infections, and although this has not been altogether borne out by experience with the graver type of case complicated by pyaemia, it is fully supported in the studies of H. F. Helmholz[1] on the susceptibility to sulphathiazole of different bacteria in urine. The drug has also had fairly extensive trials in the treatment of pneumonia, and the experience of I. F. Volini, R. O. Levitt, and H. B. O'Neil[2] is representative. They treated 169 cases of pneumococcal pneumonia with sulphathiazole, and 164 patients, sixty-nine of whom were also given serum, with sulphapyridine: in these two large groups the type distribution, frequency of bacteriaemia, and proportion of patients over 40 years of age were closely similar. The mortalities in the two groups were 5.3% and 4.2% respectively, or a difference of only two deaths. There is in fact nothing to choose between the two drugs in ultimate curative effect. Sulphathiazole brings the temperature down somewhat more slowly, and is said to have a better effect than sulphapyridine in infections by Type II and VII pneumococci, whereas sulphapyridine gives better results in Types I and III. The only important difference in effect between the two drugs is that sulphathiazole is much less apt to produce nausea and vomiting, and patients taking it are therefore much more comfortable. Only seven of these patients experienced these effects, but several had drug rashes and fever. Similar favourable results not only in lobar pneumonia but in bronchopneumonia and pneumococcal bronchitis are described by D. S. Pepper and G. C. Ham[3]; these authors gave particular attention to urinary complications, and found microscopic haematuria in four out of fifty-two cases, while crystals of acetylsulphathiazole were found in the urine of no fewer than twelve. F. W. Sunderman and D. S. Pepper[4] have determined that acetylsulphathiazole is about twice as soluble in alkaline as in acid urine, and advise the administration of alkalis in order to prevent crystallization in the urinary tract.

Meanwhile a new sulphonamide compound has made its appearance in the U.S.A. which seems in some ways to constitute a further advance. This is 2-sulphanilamidopyrimidine ("sulfadiazine"). Careful studies of its toxicity in several animals as well as its therapeutic effects have been made by W. H. Feinstone and others,[5] and a communication by Perrin H. Long[6] to the English medical press contains the assurance that favourable conclusions based on animal experiments have so far been well borne out in clinical trials. Although even less soluble in water than sulphapyridine, sulphadiazine is much more soluble in blood: it is adequately absorbed and reaches blood concentrations considerably higher than those of sulphapyridine. Both because of a low degree of acetylation and because acetylsulphadiazine is more soluble in urine

than other conjugated sulphonamide compounds, there is little reason to fear urinary tract complications; indeed, renal damage in monkeys rarely occurred even when blood concentrations of 20 mg. per 100 c.cm. were maintained for long periods. The general conclusion from Feinstone's experiments is that sulphadiazine is less toxic than either sulphapyridine or sulphathiazole, and on the clinical side Long reports entire absence of nausea and vomiting in eighty treated cases, with one case each of drug fever and drug rash. Sulphadiazine is said to be the equal of other compounds in treating streptococcal, pneumococcal, and staphylococcal infections and to excel in the treatment of infections by Friedländer's bacillus. These authors hesitate to assess relative therapeutic values because the blood concentration attained with sulphadiazine is so much higher. Theoretically this qualification is important; practically all that matters is the therapeutic effect obtainable from adequate but safe dosage. We shall doubtless hear much more of this drug.

BIOLOGICAL EFFECTS OF SHORT RADIO WAVES

That the biological effects of short radio waves are due solely to the heat produced in the tissues and not to any specific action is now generally accepted, thanks largely to the careful work of Dickens[1] in testing the claim that the 3-metre wave-length had a specific effect on cancer. This claim remained unrefuted chiefly because of the difficulty of measuring the actual temperature of the tissues, but by the use of a specially constructed copper-constantan thermocouple and by critical tuning of the transmitter Johnson[2] has now been able to maintain tissues within $\pm 0.1°$ C. of a selected temperature for several hours, both *in vitro* and *in vivo*. Provided that physiological conditions are maintained *in vitro*, the thermal death times can be measured with accuracy, being twenty minutes at 47° C. for both the Walker rat carcinoma and the Jensen rat sarcoma, and three hours at 43.5° C. Jares and Warren[3] found that the thermal death time at 41.5° C. was about thirteen hours, while temperatures below this had little destructive effect. This temperature can be maintained in the human subject for perhaps twelve hours without a fatal result, although Warren[4] has not so far maintained it for longer than five hours. Johnson shows, however, that the thermal death times *in vivo* for the rat tumours were about twice as long as *in vitro*, being six hours for the Jensen sarcoma at 43.5° C. There was, moreover, a difference in susceptibility to heat *in vivo* which was not present *in vitro*, the Walker rat carcinoma being twice as resistant as the Jensen rat sarcoma. There are several differences between the action of heat and that of *x* rays, as the radio-sensitivity of malignant growths is usually much greater *in vivo* than *in vitro*, while the histological changes resulting from heat bear no resemblance to those due to *x* rays. Johnson also found that while heating *in vitro* for the thermal death time resulted in failure to "take" on transplantation, there was no cessation of metabolic activity. This observation may be the explanation of Warren's clinical experience of artificial pyrexia—that while definitely destructive to the tumour it did not prevent its rapid recurrence. In Johnson's experiments also there was usually a swelling of the tumour of about 30% immediately after heating, which persisted for some twenty-four hours and might well be a danger clinically. His conclusion is that there is as yet no evidence that malignant tissue is more susceptible to heat than normal tissue, but the occasional regression of a tumour in man following an acute febrile illness and the successful use of toxins by Coley in the treatment of bone sarcoma must be borne in mind. A combination of *x* rays and heating was being tried by Schinz before the war, but the skin tolerance to *x* rays is definitely reduced by heating, so that what might be gained by the added destructiveness of heat on the tumour may be lost by the lowered *x*-ray dose possible without damage to the skin. There are many problems in the heating of tissues well worth investigation, and Johnson's paper has cleared the ground ready for clinical research.

SURGICAL TREATMENT OF ANGINA PECTORIS

The attainment of precision in our conceptions of the nature of a disease rarely fails to stimulate therapeutics. The accumulation of evidence for the theories that the pain of angina pectoris is due to the accumulation of pain-producing substances released by an imperfectly oxygenated myocardium, and that in angina of effort the essential anatomical lesion is narrowing of the coronary artery, has led to several attempts to improve the condition by surgery. Attempts to remedy the fundamental disturbance in the arterial supply to the heart muscle have been made by Beck[1] and O'Shaughnessy,[2] the former grafting pectoral muscle and the latter omentum to the heart. Both operations appear to provide new collateral vessels to the myocardium, and published case reports indicate some improvement in the clinical condition of the patients; but it is not yet known to what extent these operations lengthen life. Mansell[3] reported in 1940 that seven of O'Shaughnessy's original fifteen patients were dead. Another operation which has not yet passed the experimental stage is proposed by Fauteux[4] of Montreal, who has found in dogs that the high mortality from resection of the ramus descendens of the left coronary artery is reduced by previous ligature of the vena magna cordis; he proposes venous ligation to prevent subsequent attacks of coronary infarction and to relieve angina of effort in man. This operation is an example of a practice in surgery based on a principle which is not recognized by orthodox physiology; for while every physiologist would agree that venous ligation increases venous and capillary pressure, it is difficult to see how it accelerates blood flow, which is one of the effects claimed. A rather different approach to the relief of angina is to interrupt the sensory nerves carrying the pain impulses from the heart by removing the upper thoracic sympathetic ganglia or by injecting them with alcohol. Successful operations yield results that appear to be eminently satisfactory in relieving anginal pain, and there is no evidence that the patient who is deprived of the warning to limit his activity lives a shorter time thereby. But there are few cases of angina in which the pain is unilateral and in which interference with the nerves on one side suffices to abolish the pain. The operation is an extensive one, and the alternative alcohol injection, unless performed most skilfully, is apt to be followed by intractable intercostal neuralgia. Finally we come to an operation the basic principle of which remains comparatively obscure—namely, total thyroidectomy. This was introduced by Levine and Blumgart to relieve congestive failure, and was based on the well-known benefits conferred on the heart in Graves's disease by subtotal thyroidectomy. It aims at reducing the

cardiac work by diminishing the basal metabolic rate, which after operation can be maintained at the desired level by administration of thyroid. Although it has now largely been abandoned as a therapeutic measure for congestive failure in the absence of hyperthyroidism, it survives in the treatment of angina of effort, and published series of cases suggest that it has been of real benefit in many. Thyroidectomy was thought at one time to relieve angina by intercepting the sensory paths, but it seems more probable that the results are directly or indirectly due to removal of thyroid secretion, as in many patients relieved by operation pain recurs if too much thyroid is given.

The reader of most of the original papers dealing with cardiac surgery is apt to emerge with a confused idea of what these operations do and of when they should be employed. That there is doubt as to the effects of these operations is regrettable. Every therapeutic measure constitutes an experiment. Results can in many instances be assessed with considerable accuracy, and in few more accurately than in angina of effort, for in this disease Wayne and his colleagues[2] showed that the amount of exercise, performed under standard conditions, which is necessary to produce pain is remarkably constant. It is therefore a simple matter to demonstrate what measures increase and what diminish exercise tolerance. Repeated exercise-tolerance tests under standard conditions could scarcely fail to throw new light on the precise effects of these various operations. As to their place in the treatment of angina, most would agree with Sir Maurice Cassidy in his remarks concluding a discussion on the subject at the Royal Society of Medicine[1]: "As I tell all my anginal patients, this is a much-maligned disease. We are impressed by those unfortunates who succumb to or are crippled by coronary infarction; we forget those very numerous patients who live to a ripe old age in spite of their angina, or die from some other disease. Some of them *in fact cease to have angina; others learn* so to regulate their lives as not to be worried by anginal pain. Nevertheless, I agree that there is a limited scope for surgery in the treatment of this disease." In our present state of knowledge the most suitable patients are those whose lives are rendered excessively difficult by restricted exercise-tolerance or unbearable by repeated attacks of severe pain at rest. Choice of operation will be determined to some extent by the nature of the surgical skill available, but should become a simple matter as experience accumulates.

EOSINOPHILS IN THE DIAGNOSIS OF RESPIRATORY ALLERGY

The relation of eosinophils to hypersensitive states, in both man and laboratory animals, has for many years attracted the attention of clinicians and pathologists. In the laboratory, guinea-pigs and dogs are most commonly used for the study of induced protein hypersensitivity or anaphylaxis. Both species may show an increase of eosinophils in the circulating blood or internal organs during anaphylactic shock. The symptoms of acute anaphylactic shock closely resemble those which follow the injection of histamine, and probably depend on the liberation of histamine-like substances from the tissues of the test animals. This has been substantiated by the demonstration that the blood histamine is increased during acute anaphylactic shock.[3] That the eosinophilia and increased blood histamine may be intimately related is suggested by the high histamine content of eosinophils as compared with the other cellular and fluid constituents of blood.[4] These findings make it probable that eosinophilia can be regarded as an aid to the diagnosis of an anaphylactic reaction in so far as it denotes an excessive liberation of histamine. Although it is dangerous to draw analogies between anaphylaxis in laboratory animals and allergy in man, it is probable that the symptoms of both these hypersensitive states depend on the same mechanism. Eosinophilia in the blood and tissues of cases of suspected allergy can therefore be regarded as a valuable aid in the diagnosis providing it is combined with a thorough clinical investigation and the final diagnosis is made on the demonstration of an abnormal sensitivity. An increase of eosinophils in the blood and bronchial secretions is already well recognized as an aid in the diagnosis of asthma. In hay-fever, blood eosinophilia has been found less regularly, but the presence of eosinophils in the nasal secretion has been observed and used as a diagnostic sign. In a paper for which the author was awarded the Casselberry Prize of the American Laryngological Association for 1940, French[5] reports on a series of some 2,000 cases of nasal allergy in which the diagnosis was based on a cytological study of the nasal secretions together with a thorough clinical investigation, including hypersensitivity tests. In many cases repeated examinations were made, and from the collected data the author was able to correlate cytological findings in the secretions with the pathological condition of the nose and accessory sinuses. He deduces from this that the presence of eosinophils in significant numbers is evidence of an allergic state; a large preponderance of polymorphs, on the other hand, indicates an acute inflammatory complication or the stagnation of secretions. The findings suggest that in the diagnosis of common diseases of the nose and paranasal sinuses a cytological examination should be regarded as essential, and would ensure greater accuracy in the diagnosis of allergy. The recognition of the allergic basis of many common inflammatory and hyperplastic conditions of the nose would result in a reduction in the number of unnecessary surgical operations.

The *Bulletin of War Medicine* for January, the third one issued by the Medical Research Council, well sustains the excellent standard of the previous two issues and should be indispensable to all those engaged in meeting the various medical and surgical problems of war. The current volume opens with a summary of the Conference on the Treatment of War Wounds which was organized by the War Wounds Committee of the Medical Research Council last November. Then follow seventy pages of detailed abstracts of various articles relating to war medicine that have appeared in the world's medical literature. It may be noted that there are, in addition to the usual sections, short sections on industrial hygiene, food and drink, general sanitation, and organization.

The announcement of the retirement of Dr. H. A. Macewen from the post of Senior Medical Officer of the Ministry of Health will be received with very real regret by the members of the Public Health Service of the country. His work, especially during recent years, brought him into close official contact with many medical officers of health, to whom he became friend and adviser. Dr. Macewen covered a wide range of subjects in his official capacity, including control of infectious diseases, isolation hospitals, water supplies, sewage disposal, port hygiene, and surveys of the health services of local authorities. His knowledge of all branches of public health work is encyclopaedic.

REGIMENTAL MEDICAL PRACTICE

BY

HARRY POZNER, M.R.C.S.

Captain, R.A.M.C.

It is often asserted that when a doctor joins the Services he exchanges his stethoscope and clinical acumen for a sword and a uniform. That this impression is entirely erroneous has readily been appreciated by many general practitioners who accepted emergency commissions on the outbreak of war. Indeed, the scope of the regimental medical officer is surprisingly wide and comprehensive. There are certain factors which give the Service doctor a new angle, as it were, on medical practice. First, in a unit which may contain approximately a thousand men there are few, if any, cases of chronic disease. The problems with which one meets are almost entirely those of preventive medicine and administration. Among the many functions which the R.M.O. has to assume are those of medical adviser to the commander of the unit to which he is attached, medical officer of health, sanitary inspector and engineer, and, above all, that of a medical educator. There are in addition unique opportunities for clinical observation and for experiments in preventive and therapeutic medicine.

The time which any unit has to spend in action is small compared with its sojourn in rest camps, barracks, and billets, and it is to the consideration of the commonest ailments met with under these conditions that I shall devote the rest of this short article.

General Considerations

The numbers of men on sick parade naturally vary from day to day and from season to season, but from the records which I managed to keep for about a year, both in England and abroad, certain facts have emerged. The sick rate in any unit of which I have been medical officer has, with one exception, never exceeded 2½% of the total strength. This one occasion occurred in the mid-winter of last year, when a short but particularly virulent type of influenzal epidemic swept through the troops in Southern England and brought about a daily sick rate in my unit of from 3 to 9%. It also gave most of us a salutary lesson in the principles of preventive medicine. Changes in the medical officer and the moving of a unit from one area to another invariably cause an increase in the number of men reporting sick. Malingering—a beloved tradition in the old armies—is now, I believe, fast disappearing, and I have been very fortunate in meeting few of these cases. Many of these men, who previously had been cursorily diagnosed and dismissed as "lead-swingers," present genuine psychological problems, and they react satisfactorily to firm but sympathetic treatment.

Surgery

In surgery the scope of the R.M.O. is naturally limited in regimental practice to diagnosis and the minor practical procedures. Acute pyogenic infections can be treated adequately at regimental detention quarters and camp reception hospitals, and the increasing use of sulphonamides and the tendency towards conservative measures have produced the most favourable results.

The surgical armamentarium of the regimental doctor is small, but it is entirely adequate for his purpose. In the past year there have been many improvements, and to-day the field medical pannier contains a compact roll-up case of surgical instruments, a convenient efficient sterilizer, and, among other refinements, an electric auriscope.

Apart from accidental injuries, the commonest cases met with in my experience are orthopaedic problems. Injuries to bones are frequent, and recently I have had a series of six cases of fracture occurring in the region of the wrist. As with all bodies of young and athletic men, there have been the usual cases of internal derangement of the knee-joint, and where it has been deemed expedient these have been recommended for operation.

Acute abdominal conditions are rare, but they do occur, and often at the most inconvenient times. This was impressed on me during the advance through Belgium, where in the space of a week there occurred one case of acute appendicitis and two cases of perforated gastric ulcer which had previously given no symptoms. This suggested an interesting problem whether there was any connexion between the imminence of the battle and the onset of the acute conditions.

During the "blitz" and in coastal defence work there have been opportunities of treating wounds due to machine-gun fire and bomb fragments. These have all done very well when treated on the principles that have been so clearly defined by Ogilvie in his papers on war surgery. Burns of first and second degree react well to tannic acid jelly, and it is hoped that one may have the chance of testing the efficacy of silver nitrate and gentian violet in such cases. Minor surgical conditions such as haemorrhoids and sprains are frequent, and the treatment of these is on routine lines.

After the return of the B.E.F. many men reported sick with chronic suppurative otitis media, dating in the majority of cases to some heavy bombardment to which they had been subjected. These were long and tiresome cases, but it was found that they could be treated satisfactorily in the unit M.I. room by a preliminary gentle cleansing with a mixture of surgical spirit and distilled water and subsequent insufflation with iodine powder.

Before leaving this short account of regimental surgery I would like to express my appreciation of the surgeons attached to the local E.M.S. hospitals I have had occasion to use. They have always been willing and generous in their co-operation, and I have learnt much from watching their progressive technique.

Medicine

The field of regimental medical problems is extensive and provides a wide variety of cases. The therapeutic agents at the disposal of the R.M.O. are of necessity limited in number, but they are reliable and have withstood the tests of long usage. Indeed, the experience gained in employing only a small number of medicines has proved valuable at the present time, when medical supplies of unnecessary drugs have been diminished by the war.

In any well-managed unit the amount of chronic sickness is very small, and tends to be typical of that unit. For example, in any detachment of men in the Pioneer Corps—a body of more elderly soldiers—one invariably finds cases of chronic bronchitis and of arthritis. Regular battalions which have seen service in the East generally possess a case of malaria or of dysentery. But in the main the ailments demonstrated differ from those found in civilian practice only in the diseases peculiar to any large body of men who are forced to live in close proximity, sometimes under poor and unhygienic conditions.

Preventive medicine should be the constant guiding light of any R.M.O., and it is perhaps due to the realization of this that in the winter of last year were averted epidemics of cerebrospinal meningitis that might have proved disastrous. It must be persistently emphasized to commanding officers that the effective isolation of one man with a cold may prevent the unit from being decimated by a disabling illness. In every battalion there are now regimental detention quarters, where a man with a cold and a high temperature may be kept isolated and under observation for forty-eight hours.

Medical abdominal conditions are common, and one sees a number of cases of acute gastritis and peptic ulceration. The greater part of these do very well under the routine hospital treatment; but it has been observed that there is often an associated psychoneurosis. The stock complaints of the Army—constipation and its concomitant diarrhoea—are still in evidence, and much is being done, on the lines of investigation into diet and the bacteriology of food poisoning, to eliminate these conditions completely.

Perhaps the two chief problems which confront the R.M.O. are those of scabies and impetigo. Scabies may appear sporadically in a unit, especially when it has moved to another area, and the efficient control of its spread may often be an urgent question. Immediate disinfestation of clothes and blankets is of paramount importance, but the treatment of the individual has passed through many phases. The evolution of the treatment of scabies has seen the temporary popularity of sulphur ointment, Marcussen's ointment, sodium thiosulphate, and dilute hydrochloric acid, and now interest is being concentrated on the use of benzyl benzoate. With the latter some good series of results have been obtained, with very few instances of recurrence. Impetigo, although not disabling, is disfiguring, and takes a course which is long and tedious, both to the patient and to the doctor. Here again many methods, such as a weak solution of acriflavine, or mercury and ammonium ointment, have been tried. I have found that many cases react quickly and favourably to certain proprietary streptocidal preparations, and more recently to a 2% aqueous solution of gentian violet. Pediculosis, even on active service, is no longer the bugbear that it was formerly.

Certain nervous problems peculiar to the circumstances of this war have often presented themselves. These conditions, which are mostly anxiety neuroses, I have found in the older men employed in pioneer work, and in younger men who are stationed in isolated coastal defence areas The predisposing factors have commonly been worry about bombed-out evacuated families, and also the continuous nervous tension of waiting for "something to happen." A careful and accurate investigation and subsequent treatment by suggestion and encouragement have in most cases resulted in great improvement.

Abroad I saw a few cases of war hysteria. These exhibited two main syndromes. The first was automatism, and the patient tended to reproduce his actions and emotions prior to evacuation. The second and much more noticeable group was the one which exhibited facial immobility, hunched shoulders, and muscular rigidity, conditions remarkably comparable to those of Parkinsonism. These men were easier to handle, and in some instances were able to return to their normal duties after a short period at the regimental aid post.

Venereal disease, in my experience, is decidedly on the decrease. This is probably due to a wider spread of knowledge on the subject, the better education of the soldier, and the encouragement of prophylaxis. Practically all the cases I have seen are of gonorrhoeal urethritis, and have generally been relapses of an infection incurred before the war.

Active Service

No rules can be laid down for the conduct of the R.M.O. on active service. Each battle presents its own difficulties. The increasing trend towards more mobile warfare leaves the doctor further behind, and there must necessarily be a greater time-lag between the time a man is wounded and when he is seen by an R.M.O. It is not necessary to elaborate on the problems which confront a doctor in the front line, but attempting the minimum amount of emergency surgery in a shell-battered estaminet with the aid of two candles and few amenities is something to be personally experienced before it can be fully realized. With his functions so constrained in battle, he must become an expert in preventive medicine before a campaign, and during it be a constant source of encouragement to the men.

The R.M.O. holds a peculiar position. Although only attached to a unit he is as much an integral part of it as the commanding officer or the newest recruit. Correspondingly, he must identify himself with its aims and traditions. If he is to mean anything at all to a unit he must as a trained professional man mean everything that is decent and steadfast and sane.

I am indebted to Colonel J. C. Dowse, A.M.S., for permission to publish this article.

Nova et Vetera

SOME TEXTBOOKS OF FIFTY YEARS AGO

[FROM A CORRESPONDENT]

The other day I took down from its shelf an old favourite bought fifty years ago—namely, a first edition of *Life's Handicap*, published early in 1891, when Kipling was, I think, 25 years old. For no reason I can explain, after reading two or three of the stories, old friends, I began to turn over the leaves of the publisher's (Macmillan's) advertisements at the end of the book. Here, sandwiched between all kinds of other publications—hosts of sermons, editions of Greek and Latin classics, forgotten minor poetry, stacks of instructional and devotional works, and a certain number of novels (William Black, Marion Crawford, Thomas Hardy, Henry James, Bret Harte, Rolf Boldrewood, Charlotte Yonge, and others)—were quite a number of medical works: evidently the output of textbooks was a less specialized business then than it is now.

The first I lighted upon, going through them alphabetically, was Dr. T. Clifford Allbutt on the ophthalmoscope, then, we may suppose, a toy with which few general practitioners had any great familiarity. McCall Anderson's *Lectures on Clinical Medicine* comes next, of somewhat lesser interest, one imagines. Then follows Richard Barwell on *Curvature of the Spine*; and on *Aneurysm, especially of the Thorax and Root of the Neck*: possibly the former may be less "dated" than the latter. Next is Charlton Bastian on *Paralysis from Brain Disease*, no doubt still well worth reading, for he was an acute observer. Lauder Brunton is represented by six publications, three of them on pharmacology, therapeutics, and materia medica: these were still being read several years later. Bucknill on *The Care of the Insane* is perhaps forgotten by now—I do not remember ever hearing of it, though it may have been a useful work once. Brudenell Carter's *Diseases of the Eye* was a landmark in its day, and he is also represented by two smaller books on *Eyesight* and *Operations for Cataract* respectively. Carter was one of the first ophthalmic surgeons who practised as pure specialists in this country. He served as a surgeon in the Crimean War, and was a leader-writer on the staff of the *Times* for fifty years.

Cholera Epidemics in East Africa, by J. Christie, makes one think a little: Kenya and Tanganyika were in their earliest infancy, and the places where these epidemics were studied may have been Zanzibar, Mombasa, Beira, Quilimane, Sofala, and other coastal settlements. Michael Foster's *Physiology* had reached its fifth edition—stiff reading for beginners: Foster and Langley's *Elementary Practical Physiology* (a better book from the medical student's point of view) was already in its sixth edition. Dr. J. M. Fothergill was the author of three books, two on treatment and one on invalid diet: one was in a second and one in a third edition, so they were certainly being bought. Wilson Fox on *The Artificial Production of Tubercle in Animals*, and on *The Treatment of Hyperpyrexia*, sounds more interesting than W. H. Griffiths on *Prescriptions and the Art of Prescribing*, which, possibly quite wrongly, suggests the elegant mixture of some twenty or thirty ingredients, all perfectly useless but with not an incompatible amongst them. Hamilton on *Pathology*, vol. i, 25s., was evidently a textbook on the grand scale for those days, when pathology was not such a veteran science as it is to-day. Dr. Sophia Jex-Blake's *Care of Infants* would probably be nearly as useful to-day as it was half a century ago—doubtless many of the middle-aged in our profession were brought through early troubles by its use. *Klein on Micro-organisms* was in its third edition—a good book at the time too. J. A. Lindsay's *Climatic Treatment of Consumption* would probably not be of much value to this generation, though Sir Morell Mackenzie's *Hygiene of the Vocal Organs* may still have valuable lessons (it had got to a seventh edition). Surgeon General W. C. Maclean was the author of a *Textbook of Tropical Diseases*, soon to be eclipsed by Patrick Manson's classic, one may presume. More interesting are Henry Maudsley's *Physiology of Mind*

and *Pathology of Mind*, the latter more expensive than the former and doubtless larger. Charles Mercier (did any medical author ever write purer or more limpid English?) is represented by *The Nervous System and the Mind*, still a mine worth prospecting, one feels sure. Lauder Brunton, Donald MacAlister, and Mitchell Bruce were editing the *Practitioner* (then published by Messrs. Macmillan); Russell Reynolds, a *System of Medicine* in five volumes. Benjamin Ward Richardson was writing on alcohol, on sanitation, on hygiene, and on preventive medicine; Sibson's collected works were on sale in four volumes at three guineas. The *International Encyclopaedia of Surgery*, in six volumes, was edited by J. Ashhurst, jun., professor of clinical surgery in the University of Pennsylvania. Last, but very very far from least, is W. Hale-White's *Textbook of General Therapeutics*. I wonder whether Sir William still has a copy of it in his library?

RAMAZZINI AND INDUSTRIAL DISEASE

Ramazzini (1633–1714) was well known as a doctor at Modena, in Italy, who late in life became a professor of medicine at Padua. He wrote in 1700 *De Morbis Artificum*. Working among his patients at Modena he was attracted by the miserable condition of the wretched class whose duty it was to empty the cess-pits of the houses in the city. These cess-pits were only emptied once in three years, and he found that the men could only work four hours a day and were invariably ill. This led him to inquire into the industrial diseases in other groups of workers and thus led to the production of a book of great interest, often pillaged by other writers without acknowledgment. The second edition appeared in 1713. It is now published under the auspices of the library of the New York Academy of Medicine.[1] Written in Latin, it is translated by Mrs. Wilmer Cave Wright, Emeritus Professor in Greek in Bryn Mawr College. Her English translation faces each page of the Latin original. It is fluent and accurate. She has prefixed an excellent introduction, has appended notes, and given two indexes.

It is interesting to notice how such a book, on industrial diseases, written in the eighteenth century, differs from modern ones. Some of Ramazzini's observations were made from personal knowledge, others he knew only by report. He was widely read in the classics and quotes freely from Hippocrates, Pliny, and Galen. Although he is accurate in many points he was credulous, making little attempt to verify the opinions expressed by the ancients. He makes no allusion to such a condition as anthrax, but he lays stress on the effects of lead and mercury. The whole book reminds one a little of Burton's *Anatomy of Melancholy*, and may be read with profit and pleasure by the general reader as well as by those who desire to ascertain what was known of industrial disease at the time it was written.

[1] *De Morbis Artificum. Bernardini Ramazzini. Diatriba. Diseases of Workers.* The Latin text of 1713. Revised with Translation and Notes by Mrs. Wilmer Cave Wright. (Pp. 534. 30s. net.) Chicago: University of Chicago Press. 1940.

At a recent meeting of the Section of the History of Medicine of the Royal Society of Medicine, with its President, Sir Walter Langdon-Brown, in the chair, Dr. J. D. Rolleston read a paper on the medical aspects of Saint Simon's Mémoires, which covered the last twenty-four years of the reign of Louis XIV and the eight years of the Regency (1691–1723). He discussed the subject under the three headings of prevalent diseases, of which the most important were small-pox, malaria, syphilis, tuberculosis, gout, nervous and mental disorders, alcoholism, fistula in ano, and stone in the bladder; descriptions of contemporary physicians and surgeons, especially Fagon and Maréchal; and miscellaneous topics including longevity, sexology, spas, poisoning, post-mortem examinations, and the illnesses of Louis XIV.

ENGLAND AND WALES

Retirement of Islington M.O.H.

Dr. G. Clark Trotter has retired from the position of medical officer of health for Islington after nearly twenty years in the service of that borough. Previously he had been medical officer of health for Paisley and for Deptford. At a recent meeting at Islington town hall the mayor, on behalf of the staff of the public health department, presented Dr. Clark Trotter with an electric wireless set, and he and the mayoress also made a personal gift of books. The ceremony was presided over by Dr. V. Freeman, Dr. Clark Trotter's successor, who remarked that during the tenure of the late medical officer the infant mortality of Islington had fallen from 130 per thousand births to 60, while reforms such as slum clearance and the stopping of food adulteration owed much to his initiative. Speeches were also made by the chairman of the public health committee, the deputy medical officer of health, and the superintendent of the public health department. In acknowledging the compliments paid him Dr. Clark Trotter said that the work of the health department of such a large borough was by no means a one-man job, and without the support of his loyal colleagues he could not have carried through.

The Air-raid Shelter Problem

Lord Horder presided at a meeting of the Royal Empire Society on March 4, when Mr. T. L. Tanner, chairman of the Friends Ambulance Unit, spoke on the shelter problem. The position with regard to shelters, Lord Horder said, still remained not entirely satisfactory. The policy of his committee had been a dual one—a short-term policy aiming at rectifying the errors of last September, when the need for dormitory shelters suddenly arose, and a long-term policy summed up in the single word "dispersal." By dispersal he believed the maximum of safety and of hygiene could be obtained. He had been accused, he said, of stating that there was no such thing as an ideal shelter; what he had said was that there was no ideal large public shelter. But however satisfactory the small shelters (Anderson and domestic) might be, the persistent preference of people for the public shelters must be considered. These public shelters had become the framework of a new social existence. A strange thing, as Lord Horder commented, that an active communal life should start underground in conditions so primitive that it was a struggle to get any sanitation established. He hoped that one of these days a new turn in the war would make the whole of this troglodytism unnecessary. But the fact must be faced that there was a hard core of people who believed implicitly that public shelters were safer than they really were and as offering a more comfortable existence than anything above ground. Care must be taken, said Lord Horder, that underground slums were not created, that the casual shelterers, having passed through the transition stage of the dormitory shelter, did not become the inhabitant of an underground slum. He referred to some large underground shelters he had seen in the Provinces, with conditions worse than anything in London. The saddest spectacle was the children. It was all very well to say they should not be there at all, but the distrust of reception areas by their mothers must be reckoned with. Lord Horder still felt that dispersal was the best policy, but it took time to unload these large public shelters, and in the meantime the people who stayed in them must be kept safe and healthy and with as much spiritual happiness as possible.

Mr. Tanner said that overcrowding in the shelters had diminished both as a result of the provision of new shelters and still more the reduction in the frequency and length of night raids. There had been cases of cerebrospinal fever and measles and whooping-cough which might be attributed to shelter conditions, but as yet no large-scale epidemic. He thought there was room for improvement in the organization of doctors' rotas, and that sometimes the visits made by

UNTIL 1932 surgical anæsthesia could only be achieved by inhalational administration. The introduction of 'Evipan' Sodium, the original intravenous anæthetic, furnished the anæsthetist with a convenient, rapid and agreeable method of introduction, the value of which has been proved beyond question.

This pioneer product has been administered on over 7,000,000 occasions.

doctors were perfunctory. The late Minister of Health had announced the setting up of medical aid posts and isolation wards. The former had been installed in shelters of over 500 capacity, but in many instances isolation wards were not to be found. While alive to the disadvantages of a large public shelter (the published reports of early shelter conditions were in no way exaggerated), Mr. Tanner pointed out that there was something to be said now on the other side, especially the opportunities for providing good food and food-education and recreational facilities and the fostering of a community spirit.

Correspondence

Abdominal Hyperaesthesia in Dyspeptics

SIR,—I am sorry that Captain W. G. Mills should have attempted to revive in your issue of March 1 (p. 315) a method of diagnosis which had been allowed to fall into well-merited oblivion for twenty years. I believe that cutaneous hyperaesthesia as a sign of organic disease of the stomach is quite valueless, and that when it is found it has invariably been produced by the unconscious suggestion of the observer. From the time when, as a student in 1903, I first read Head's work on the association of cutaneous hyperaesthesia with visceral disease I mapped out his areas in every case I saw in which an ulcer had been diagnosed. I watched its retraction from day to day until it finally disappeared, when it was assumed that the ulcer had healed. In 1909 I examined nine patients with duodenal ulcer the day before they were operated upon by Moynihan. Greatly to my surprise I failed to discover hyperaesthesia in any of these phlegmatic middle-aged Yorkshiremen. I soon realized that the cases I had previously examined were mostly highly suggestible chlorotic girls, who were not suffering from chronic ulcer at all. Since 1909, by taking care to avoid suggestion, I have never observed cutaneous hyperaesthesia in any of some hundreds of cases of ulcer. On the other hand, I have often suggested an area of hyperaesthesia away, replaced it by anaesthesia, or transferred it to the opposite side after it had been marked out by one of my clinical clerks.

It is curious that in the last war cutaneous hyperaesthesia over the heart was regarded by some physicians as evidence of D.A.H., a *functional* disorder, in contrast with Captain Mills's hyperaesthesia sign of *organic* gastric disease. The precordial hyperaesthesia, like the cutaneous hyperaesthesia over the shins, described by one medical officer as pathognomonic of trench fever, proved to be the product of the observer's own unconscious suggestion.

The remarkable suggestibility of the average soldier was demonstrated in 1918 by the discovery of anaesthesia of the pinna of the deaf ear in eighteen out of twenty-eight otherwise fit soldiers with unilateral organic deafness, compared with one out of nine civilians.[1]—I am, etc.,

ARTHUR HURST.

Oxford, March 1.

Hyperventilation and the Effort Syndrome

SIR,—Drs. E. Guttmann and Maxwell Jones, in their article on hyperventilation and the effort syndrome (November 30, 1940, p. 736) have questioned the theory that hyperventilation plays a role in the cause of the symptoms of the effort syndrome. As the originator of this theory (that effort syndrome represents an anxiety state with hyperventilation), I feel that a letter justifying my beliefs is warranted.

Most interested observers will agree that effort syndrome results from anxiety (fear) plus exertion under conditions of stress and strain. In my own experience those patients sent to me with this diagnosis made by impartial physicians invariably have had anxiety states and have had their major symptoms reproduced by voluntary overbreathing, even though they were not aware of the reason for going through this test. Most of these patients re-experienced their symptoms after doubling or trebling their respiratory volumes for one to three minutes or so, and in turn were relieved by breathing 2 to 5% carbon dioxide (mixed with pure oxygen or with 21% oxygen and 77 or 74% nitrogen respectively) for thirty to sixty seconds. When occasionally most but not all of the symptoms were reproduced by this procedure, it seemed to be due to the fact that sympathetic or parasympathetic stimulation, or both, had played a part in their spontaneous attacks. In our original publication (Soley, M. H., and Shock, N. W., *Amer. J. med. Sci.*, 1938, **195**, 840) these latter factors were not considered adequately, and they probably play a greater part in effort syndrome than we originally supposed. Of course, hyperventilation and sympathetic and parasympathetic stimulation can all arise from central nervous system overactivity caused by fear, anger, and other emotions. I believe that combinations of these responses to anxiety account for the variations in the clinical picture called the "effort syndrome."

If one considers palpitation and tachycardia only as effort syndrome, then it is obvious that these symptoms will not be caused alone, or even at all in some patients, by hyperventilation, since they are probably direct sympathetic effects or are partially mediated through the secretion of the adrenal medulla. But if one includes those symptoms described by Sir Thomas Lewis and Paul D. White as being characteristic of effort syndrome, then hyperventilation alone or with sympathetic and parasympathetic effects will produce this syndrome.

The rate at which the patients overbreathe is very important, since with too rapid a loss of carbon dioxide through the lungs the patients fail to experience the symptoms which appear following less rapid loss of carbon dioxide. In our first trials with hyperventilation we often made this error of hyperventilating patients too rapidly.

Inasmuch as effort syndrome is of such importance in the armies of both Great Britain and the United States, as well as in civil populations, any information which ultimately leads to the discovery of its aetiology should be a worth-while contribution.—I am, etc.,

Trichiniasis in Britain

SIR,—In addition to the two Pembrokeshire outbreaks (1922 and 1939) mentioned in his letter of February 20 by Dr. Gillam, there was trichiniasis in a household near Swansea in June, 1930, affecting four persons acutely and one in very mild form. I investigated the outbreak in conjunction with Drs. Joseph Lloyd and J. Lloyd Davies and with officers of the Welsh Board of Health and the Swansea Public Health authority, and it was decided that a ham (purchased locally but probably originating from a Midland firm of wholesalers) was the source of the infection, though complete proof was lacking.

There was some evidence that the rapidity of swelling of the eyelids was correlated with the degree of severity of the disease.

Case	Swollen Eyelids	Severity	Eosinophils per c.mm.
A	13th day	Very severe	2,722
B	13th "	Severe	5,376
C	15th "	"	2,976
D	20th "	Moderate	1,500
E	Not seen	Very mild	1,060

In all cases the cell counts were made on the twentieth day after ingestion of the suspected ham. Although careful search for other cases in the district was made by the health authorities none was found, and ultimately all the patients recovered.—I am, etc.,

A. F. SLADDEN

Swansea, March 3.

Scabies

SIR,—I was interested in Dr. Bigham's letter on scabies in the *Journal* of February 22 (p. 294). In this district also scabies is endemic, but of late has assumed major epidemic proportions. Several factors have almost certainly contributed to the wide and rapid spread of the contagion. For example, it is known that Service men come home on leave while

[1] Hurst, A. F., Symns, J. L. M., and Gainsborough, R. (1918), *Scale Hayne Neurological Studies*, 1, 19. London. See also Hurst, A. F. (1920), *Crooman Lectures on the Psychology of the Special Senses*, p. 50. London.

infested. Crowding of persons together in air-raid shelters and a certain influx of people from other areas have greatly favoured the rising incidence of scabies.

The usual means of dealing with scabies by treating children at clinic baths and instructing mothers is not only inadequate but, in the vast majority of cases, a futile expression of hope. Formerly it was at least possible to keep the disease in check by such methods. To be of any value in present circumstances treatment must be extended not only to children but to the other members of households, most, if not all, of whom will be found infested. Herein lies the greatest difficulty. Post-school and adult persons do not often seek treatment for scabies in its early stages. It has been found that when they do the family doctor's instructions are disobeyed, particularly where staying off work is included in orders. In this area a large proportion of houses lack bathing facilities. Chemists are not infrequently consulted, and they supply sulphur ointment and advice. In some instances one or more members of a family may attain a state of partial or almost complete cure for a short time, but a vicious circle of reinfestation from kith and kin is kept going and we find a more or less chronic form of scabies. This is very often complicated by infection resulting in severe impetiginous or other septic sores. In my opinion the additional bathing and washing facilities afforded by decontamination stations will in no way relieve the situation. In my view hospitalization of whole families is the most efficient and, in the long run, by far the least costly way of dealing with scabies. Some areas may be fortunate enough to have available for this untenanted small-pox hospitals which could be utilized.

Victims of scabies lose sleep and rest—a state of affairs seriously affecting the working capacity of many engaged in nationally important industries. The treatment of the condition is indeed one which merits the attention of civil defence authorities. It is therefore suggested that, where possible, staff difficulties be obviated by seconding auxiliary and assistant nurses from other civil defence duties to that of combating the scabies scourge. Under such a scheme as the foregoing it should be possible for scabietics to follow their employment, going to work from hospital and returning there until cured. In the meantime the houses vacated should be "fumigated," so that on the families' return after a few days' to a week's treatment there should be no risk of reinfestation.

I heartily agree with Dr. Bigham that the present situation regarding scabies is one requiring urgent and nation-wide attention. My suggestions may be practicable in certain areas; in others such methods will be out of the question and, as in everything else, local conditions will govern whatever measures may be taken. It would be interesting to get the views of others dealing with this problem.—I am, etc.,

N. M. MACDONALD

Department of Health, Rotherham, March 3.

Control of Lice

SIR,—I have read with considerable interest Prof. P. A. Buxton's article on the control of lice in the *Journal* of November 2, 1940 (p. 603).

During the typhus epidemics which have occurred in this town of recent years we have naturally been interested in the destruction of lice on clothing and on people; and in the course of certain very crude experiments we made a somewhat interesting observation which, in spite of the crudeness of the experiment, appeared to be a quite definite fact—namely, that ammonia (that is, ordinary solution of ammonia), if added in varying percentages from 2 to 4, increased the toxicity of cresol products in a most astonishing way, and, furthermore, that crude cresols containing large amounts of quinoline and naphthalene products were very much more effective than the more purified types.

We used these solutions to supplement our inadequate steam disinfection facilities, but it seems to me that the information may be of value to people in a better position to perform accurate experiments than we, as a purely routine establishment, are. Incidentally, we found this crude solution was not without value in diminishing the incidence of bed bugs in camps.—I am, etc.,

J. H. JORDAN.

Public Health Department, Shanghai, Jan. 16.

Air-raid Casualties

SIR,—You are to be congratulated on publishing the very frank account of some recent air-raid casualties by Dr. Margaret Ball and Mr. George Quist (February 22, p. 273), disturbing though it is in several respects.

That replacement of fluid is not sufficient in itself to overcome severe shock is a conclusion which to many will not be unexpected in spite of recent more optimistic reports. Whatever the end-results it would seem to many that there is a nervous factor still undetermined which is, of course, quite unaffected by mere administration of fluid, and, indeed, it would seem that it is probably only those persons with a certain nervous make-up who do show shock in its very worst forms. It would be of value to know if there were patients amongst those treated on this occasion whose injuries were apparently as severe and yet in whom shock was less marked.

The other and more disturbing fact noted by Ball and Quist was the delay in operating on two patients who later developed gas gangrene and in whom quite frankly they believe the delay was a not unimportant factor in the development of this most serious complication. One cannot help thinking that with other emergency hospitals within a stone's throw this might have been avoided. The fact that casualties occur on one or other side of a thoroughfare should be no excuse for using hospitals in one sector only, as would seem to have happened in this instance.—I am, etc.,

March 2. W. L. TEMPLETON.

SIR,—It is a little difficult to supply all the data requested by Dr. W. F. Bensted-Smith (*Journal*, March 8, p. 379). Most of the casualties have been admitted within thirty minutes of the accident, and from within a half-mile radius; the importance of blast is almost impossible to determine. It is very likely that a lot of the tourniquets are applied by unofficial agents such as patients' friends, etc., but quite apart from its incorrect application it is doubtful that it is a good thing to cut off the blood supply to an injured limb, particularly when in most cases a local dressing will suffice to stop bleeding.

The estimate of results of resuscitation is complicated by the lack of uniformity in the standards of definition of shock in its various degrees, and any comparison of cases is thereby rendered difficult.—We are, etc.,

MARGARET BALL.

London, W.C.1, March 10. GEORGE QUIST.

First-aid Parties at Scene of Incident

SIR,—With reference to recent correspondence regarding the duty of first-aid parties at the scene of incident, I think it might be of interest to state that for some months we have been teaching our first-aid parties that rapid clearance (and only absolutely essential first aid) was their primary concern at a scene of incident. We cut out elaborate bandaging and splinting and stressed the importance of getting cases off to hospital as soon as possible. All our ambulances carry hot-water bottles. Tourniquets are seldom applied. Exercises in the dark are part of our training scheme.—I am, etc.,

G. C. F. ROE.

Halifax, March 5. Medical Officer of Health.

Too Much Morphine?

SIR,—Recent communications in the *Journal* give the impression that the administration of morphine has been almost routine in the treatment of serious air-raid casualties. It appears to me that far from being a life-saving measure the giving of morphine makes for death not life. Morphine depresses respiration, so that in "blast" cases it would seem to be particularly undesirable. The depression of the nervous system, moreover, in all probability diminishes retraction of the blood vessels and increases the danger of haemorrhage.

In the treatment of over ninety cases of almost all degrees of severity morphine was administered in only two cases; they were of minor but painful eye injuries. The behaviour of the injured was extraordinarily good. With the exception of one man with a fracture of the scapula, who was very fat and had great difficulty in finding a comfortable position, there was

scarcely a groan or complaint and gratitude and appreciation were freely expressed.

Two lessons were learnt. (1) Haemorrhage was not infrequently concealed by the covering up of wounds with large dressings of cotton-wool. It was found that half an hour's steady pressure by an attendant was often necessary to arrest haemorrhage from even a small wound. (2) The value of really hot applications, especially over the heart in cases of shock and (usually) exposure, was apparent. Relays of turkish towels "cooked" in a gas oven were used.—I am, etc.,

March 6. LENNOX JOHNSTON.

Amputation of the Index Finger

SIR,—Although surgical textbooks well-nigh universally proclaim that in operations on the fingers the absolute minimum of tissue should be removed and as much functional length conserved as is possible, I have often wondered if the short stump left by amputation of the index finger at the proximal interphalangeal joint is not more of an obstruction to the function of the hand than an aid.

Recently I had the good fortune to encounter the ideal authority to settle this question—a bootmaker who, because of injuries sustained in a factory accident several years ago, had his index fingers amputated in different ways: the right index was amputated at the proximal interphalangeal joint, and the left through the neck of the second metacarpal bone. On examination the stump of the proximal phalanx and its coverings are seen on the right hand; it is mobile and warm, and has the amputation scar on the dorsal surface. The skin over the free end is stretched and shiny, but is not tender to the pressure of an examining finger. The left hand has a neat and unobtrusive appearance, the neck of the second metacarpal having been divided obliquely; the scar is a dorsal one and not at all obvious. The grip of the left hand is more powerful than that of the right. This man is quite emphatic that his left hand is now the more useful one, despite the fact that he is right-handed, and he expresses the wish that he could get rid of the offending stump on the right hand. It is neither long enough nor strong enough to use in apposition to the thumb in grasping, and consequently the middle finger performs this function of the normal index finger, while the stump, encroaching as it does on the space between the thumb and the middle finger, is really an obstruction to this action unless it is dorsiflexed out of the way. In this latter position the stump is liable to receive knocks on its free end—an event which is followed by severe pain lasting for several hours. The loss of the index finger of the left hand causes little inconvenience, as the middle finger has assumed the role of the index with full competence. The man does not feel this hand to be any weaker than it was before the accident.

Surely the evidence of this illustrative case weighs heavily against the leaving of a short index stump, and favours oblique division through the neck of the metacarpal bone. The loss of the metacarpal head may weaken the architecture of the hand by the necessary division of the deep transverse ligament of the heads of the metacarpals; yet this is compensated by the improved appearance and the regularity of the important cleft between the thumb and the middle finger.—I am, etc.,

St. Andrews, Feb. 20. H. A. HANTON.

Cut Tendons: An Appeal

SIR,—Following my initial letter on this subject you have published correspondence from others who have testified that they also have never seen a successful result following digital flexor tendon suture by any known method. No one has come forward to champion the present routine method of suture employed throughout the land. We still teach students that flexor tendons should be sutured with full aseptic technique by an experienced surgeon, whereas it would appear that under all circumstances the finger is ultimately stiff and after weeks of unemployment—in the case of highly skilled men on work of national importance—the finger is finally amputated.

May I ask one pertinent question? Is there a single surgeon in the land—general or orthopaedic—resident medical officer—past or present—who has succeeded in establishing a return of movement (active) in the interphalangeal joints after any method of primary or secondary suture of flexor tendons within their digital sheath. If no such success has been obtained, is it not our duty to advise and carry out primary amputation and so get these injured workpeople back to work in as many weeks as it now takes months? If tendon suture is worth the effort and labour now expended, surely someone will sponsor it.—I am, etc.,

Sheffield, March 6 H. BLACOW YATES.

Vitamin K in Obstructive or Surgical Jaundice

SIR,—In his letter (February 22, p. 292) Dr. R. N. Herson takes exception to the statement in my article (January 25, p. 111) that lack of clotting power in cases of obstructive jaundice can be corrected by the use of vitamin K. I quite agree with him that not all of these cases will respond to vitamin K, and I am sorry if my remarks on the subject claimed too much for the treatment.

Lack of clotting power is due to prothrombin deficiency. Prothrombin is manufactured by the liver from vitamin K supplied to it from the intestine. For the absorption of vitamin K the presence of bile in the intestine is necessary, but this is denied it in cases of obstructive jaundice and it is necessary to supply the vitamin by some other means. If the liver is so hopelessly damaged that it cannot utilize the vitamin, then obviously the treatment is of little avail. The less the response of the liver to the treatment, the greater the hepatic insufficiency; in fact, the response might be taken as a measure of liver function.

The finding of white bile in the common duct, as in the case quoted by Dr. Herson, argues prolonged obstruction and superadded infection. In such cases the liver is so severely damaged that the outlook is poor whatever the treatment or however great the surgical skill. But happily the majority of cases of obstructive jaundice are not of this extreme nature, and the liver will be found to respond. It is advisable, if operation is undertaken, that the treatment with vitamin K should not only be carried out before but continued after operation. Where the response of the liver is not good the treatment must, as in Dr. Herson's case, be supplemented with blood transfusions. By blood transfusions prothrombin is supplied direct, though the increase in prothrombin by this means rarely exceeds 10% to 15%. Fresh blood is preferable because of its platelet content. Plasma, in these cases, is perhaps not as good as blood, certainly not as good as fresh blood. It has been estimated that the prothrombin content of stored plasma falls to 40% in the first week, and to 15% in three weeks.

I was not aware that undue claims had been made for the efficacy of vitamin K in cases of obstructive jaundice. Dr. Herson's letter suggests that such claims are common in the literature. Certainly many surgeons in America have testified to the benefit of the treatment in cases under their care. They have not hesitated, however, to draw attention to the fact that there were cases which did not respond to the treatment, and in these cases post-mortem examination showed that very little normal liver tissue could be found.—I am, etc.,

London, W.1. MICHAEL J. SMYTH.

Prosthetic Ulcer

SIR,—Mr. H. T. Simmons has performed a useful service in giving such a careful description (January 25, p. 119) of a not uncommon benign dental condition which, on account of its resemblance to carcinoma, is liable to lead to unduly extensive treatment and a pessimistic prognosis, as he points out. I have known such a case demonstrated as an epithelioma to a Fellowship course at a teaching hospital. He correctly states that the condition is not described in the surgical textbooks. The dental literature[1] contains several references, which are, however, rather inadequate. Prinz and Greenbaum,[2] and also Wright,[3] give fair descriptions, and the latter includes the histology.

Hyperplasia of the gum due to ill-fitting dentures is, however, well recognized by dental surgeons. Cases are not infrequently shown at clinical meetings, and I have personally

[1] *Oral Surgery*. By S. V. Mead. London, 1940. pp. 644, 1201.
[2] *Diseases of the Mouth and their Treatment*. London, 1935. p. 217.
[3] *Dental Cosmos*, 1934, 78, 911.

demonstrated two. The alveolar mucoperiosteum readily undergoes hyperplasia as the result of irritation, and I consider polypus of the gum, fibrous epulis, and this condition to be somewhat similar.

The term "prosthetic ulcer" is widely used to denote the small ulcers frequently seen in relation to a denture, whether due to lack of fit, excessive bite, hard foods, or other conditions. In the type described the basic change is a hyperplasia, as Mr. Simmons so well shows. It is usually ulcerated when seen by the surgeon, because it is the pain and fear of malignancy that cause the patient to seek treatment. I think this condition should be differentiated by the use of another name, for when the dentures are discarded there is no ulcer but the hyperplasia remains. "Gingival fibromatosis" and "gingival hyperplasia" can both be confused with other conditions, and "hyperplasia of the gum due to ill-fitting dentures" is probably the most accurate, if lengthy, term.

These patients already have excessive absorption of the alveolus, so that care must be taken in treatment lest cicatricial tissue develop and make the successful fitting of a stable denture still more difficult. I am interested that Mr. Simmons obtained good results by diathermy. Certain cases are suitable for excision and the insertion of buccal inlay. Slow but effective is the well-established method of ensuring that no dentures are worn for twelve to eighteen months, and this is often preferred by the frail and elderly patients subject to the condition. In the less severe cases drastic easing of the denture is sufficient, and I have one such case under treatment at present.

The prominence of Mr. Simmons's opening statement is unfortunate, for the statistics of a radium institute surely give no safe indication of the relative incidence of innocent and malignant tumours. Accurate statistics of this type are most difficult to obtain, but if odontomes are classed as tumours, it is my belief that tumours of the buccal cavity are more frequently benign than malignant.—I am, etc.,

London, S.W.1, Feb. 25. B. W. FICKLING.

Cyclical Mucosal Ulceration

SIR,—It would seem difficult to exclude recurrent herpes as an explanation of at any rate some cases of "cyclical mucosal ulceration" of the type Dr. M. H. Pappworth describes in his article (February 22, p. 271), and particularly of those in which ulcers are associated with menstruation.

When acquired in early life—the primary infection apparently being the common aphthous stomatitis of children—the herpes virus appears to persist more or less indefinitely, lying latent in epithelial cells until activated by some local or general disturbance, such as, for instance, the menstrual function. After the face, where of course it often recurs with extraordinary persistence and at regular intervals, sometimes in the same area each time, the commonest site for recurrent herpes is the genital region. Catamenial herpes is a recognized type, and certain women have an outbreak either around the mouth or on the genitals at nearly every menstrual period. Any portion of the vulva may be affected and occasionally the vagina and cervix uteri. In these situations or in the mouth, where the affection is certainly less common, the herpetic vesicles because of friction and maceration are ephemeral, being quickly transformed into superficial erosions so that the lesions may present a varied appearance.

Although as a rule herpes only affects one area at a time, it has been observed on a number of different sites simultaneously.

From Dr. Pappworth's description, the ulcers in his cases are suggestive either of herpetic erosions or of common aphthae. They were all apparently very small and superficial, were surrounded by an inflammatory halo, and were preceded by and associated with pain. They often appeared to begin as papules or vesicles and most of them lasted only two or three days. All healed without leaving scars. They would not seem to correspond to the lesions either of so-called "periadenitis mucosa necrotica recurrens" (Sutton, sen.), which begins as a painless submucosal nodule later necrotizing in the centre and leaving a crater extending well into the corium with marked induration of surrounding tissues, or to Lipschutz's "ulcus vulvae acutum," even of the milder veneroid type, in which new ulcers appear as old ones heal so that the disease lasts a month or longer. Moreover, relapse has been noted in only a small proportion of cases of this disease—one of Lipschutz's patients, for instance, had seven attacks in nine years.

Regarding Dr. Pappworth's statement that recidivating buccal and genital ulceration seems to be peculiar to women, Dr. Dowling some while back had a man under his care at St. Thomas's Hospital with severe and more or less persistent ulceration of the mouth in whom a number of ulcers of a more superficial though not herpetic type also appeared on the penis and scrotum. Dr. Dowling considered he probably came into Sutton's group. O'Leary (*J. Amer. med. Ass.*, 1932, **98**, 466) saw a case in a male in whom the posterior part of the scrotum and penis was involved in association with ulcers in the mouth. It is interesting to note that in one of Whitwell's cases (*Brit. J. Derm. Syph.*, 1934, **46**, 414), that of a man of 34 in whom mouth ulcers were associated with attacks of iritis, on one occasion four transitory herpetic erosions were observed on or behind the corona of the glans penis. Another of Whitwell's cases referred to by Dr. Pappworth, a woman of 29, had been subject to recurrent labial herpes provoked by colds or sunlight. These outbreaks were then replaced by weekly attacks of mouth ulcers of a deeper, more ulcerative type, with several of which were associated vulval ulcers.

The nature of these lesions, especially of recurrent buccal ulceration, which is a most trying and by no means uncommon affection, is certainly very puzzling, and there is at present much confusion in their nomenclature and classification.—I am, etc.,

Harley Street, March 1. E. W. PROSSER THOMAS.

Combined Trigeminal and Geniculate Zoster

SIR,—I have read with considerable interest the article by Major John D. Spillane on his case of combined trigeminal and geniculate zoster (February 15, p. 236). There is one point, however, on which I am a little uncertain, and on which the textbooks are not very helpful. I was under the impression, possibly mistaken, that a neurotrophic virus progressed along nervous connexions, and could not, so to speak, "jump gaps." If this is so the anatomical pathway suggested by Major Spillane is a little puzzling.

The greater superficial petrosal nerve (Birmingham nomenclature—Major Spillane says "superior," but presumably refers to the same nerve), although it lies in close relation to the ganglion trigeminale, does not actually connect therewith, and in fact does not pass through the cavum trigeminale, which houses the posterior part of the ganglion. The only possible true anatomical connexion seems to be via the internal carotid plexus, which gives branches to the ganglion trigeminale and to the deep petrosal nerve. This latter does connect with the greater superficial petrosal to form the nervus pterygoideus. These branches, however, are minute in the extreme. The external petrosal nerve is, by all accounts, so inconstant and so small that it seems risky to postulate it as a track for the virus, especially as again the connexion is only through plexuses on the internal carotid and middle meningeal arteries.

Of course, if the virus is not strictly limited to purely nervous pathways, then the question does not arise, but I should be interested to know if this is so. Major Spillane's article implies this in suggesting a route via the greater superficial petrosal nerve.—I am, etc.,

March 3. ROBERT G. W. OLLERENSHAW.

Damp Beds and Angiospasm

SIR,—In your issue of February 22 (p. 296) Sir Leonard Hill mentions the heat given out when dry clothing is moistened—as by the patient's skin. May I comment on the reverse of the picture and thus remedy an omission in my paper on "Blunders of Plain Muscle" (*Lancet*, September 27, 1937).

A good deal of body heat is needed to convert into vapour the water contained in cold underwear or bedclothes, especially

if they are damp. People with an enthusiastic circulation can usually supply this body heat. But there are certain people of the anxious, striving temperament who are liable to spasm in any of their tubes or sacs lined with plain muscle. This leads to asthma or migraine, spasm of the pylorus or colon, goose skin, cold extremities, and the like. When persons of this type undress in a cold room or get into a cold bed the arterioles of their extremities go into spasm. Unless aided by a hot bottle or hot bath their extremities remain cold and they cannot sleep till warmed. If the bedclothes are damp, their cold skins are unable to supply the considerable heat needed to vaporize the water in the damp sheets. Their fussiness about well-aired bedding, though well founded, makes them the laughing-stock of people with normal circulations.

I read that in Tibet a holy man will have his holiness assessed by sitting beside a hole in the ice while his friends drape his naked body with a sheet wrung out of the ice-cold water. His holiness is measured by the number of sheets he can dry successively by his body heat. I fancy five was the record! The test will at any rate eliminate any circulatory anxiety neurosis, and perhaps this may be one index of a mind completely satisfied by religion. For it is asserted by T. A. Ross in his book on psychotherapy that the truly religious never become neurasthenic. But in this country I fear our habits of comfort (and religion?) render most of us incapable of airing our own beds; certainly those liable to angiospasm cannot do so.—I am, etc.,

Hull, Feb. 25. FRANK C. EVE, M.D., F.R.C.P.

Experimental Human Scurvy

SIR,—The paper by Dr. F. W. Fox on experimental human scurvy (March 1, p. 311) raises some important points. We are asked to believe that the classical picture of scurvy is considerably overdrawn. In a quotation from Hess the implication is given that Lind stated that the indolent and slothful sailor was the first to suffer from scurvy. What Lind says (*Treatise on the Scurvy*, third edition, 1772: Postscript, Sect. IV: Observations on the Causes Productive of the Scurvy) is: "Lastly, troops that have undergone much fatigue, as also sailors who have worked very hard, may become afflicted with this disease; whence it may be also inferred, that confinement, sloth and indolence, though frequently, are yet improperly assigned, as causes of the scurvy." From Dr. Fox's article it would appear that the really active do not develop scurvy. Might it well not be that the indolent and slothful are so because of their lack of ascorbic acid?

With regard to the relation of gingivitis to scurvy the following quotations from Lind (*Scurvy in Hampshire*, p. 271) are of some interest:

"*In Haslar Hospital* the appearances of the disease were various. . . . The gums were not always affected. . . . Several complained of extreme weakness and a pain in the back." "The gums of several bled, being sore and spungy, without their having any other symptom of the scurvy. One person was greatly alarmed with a spitting of blood for three days, which I found to be no more than the scurvy affecting his gums."

—I am, etc.,

ROBERT COOK,
Lecturer in Biochemistry, University College, Dundee, University of St. Andrews.

Dundee, March 4.

Malignant Measles?

SIR,—Dr. Audrey Z. Baker writes (March 8, p. 380) that a case which she describes "may be worth putting on record" as one of "black" or malignant measles. Comment has already appeared in the daily press, but I doubt if it should be recorded in medical history as an additional case.

The description given by Dr. Baker is an excellent presentation of the symptoms, signs, and course of acute suprarenal insufficiency, usually known as the Waterhouse-Friedrichsen syndrome. While the aetiology of the condition is obscure it is relevant to inquire if there have been any cases of meningococcal meningitis in the district.—I am, etc.,

W. H. PATTERSON.

Booth Hall Hospital, Manchester, March 8.

Nurse Anaesthetists

SIR,—In his letter of March 1 (p. 339) Dr. W. Stanley Sykes accuses the University of Cambridge of taking a "retrograde step" and instituting "that bane of the second-rate American medical school—the nurse anaesthetist." This "retrograde step" has been taken by Addenbrooke's Hospital, which, apart from an arrangement with regard to elementary teaching and the provision of facilities for examinations, has no connexion with the University, the Governors directing and controlling the whole administrative work of the hospital. In fact, the honorary staff, though represented on the Faculty Board of Medicine of the University, did not bring this action to the notice of the University.

It is difficult to imagine anything more unworthy of a graduate of this university than Dr. Sykes's action in making this accusation, accompanied by a threat, without attempting to ascertain the facts from the Secretary of the Faculty Board or any other person competent to give him accurate information, or even consulting the Ordinances.—I am, etc.,

RAYMOND WILLIAMSON,
March 10. Secretary of the Faculty Board of Medicine, University of Cambridge.

SIR,—The following extract from a judgment given in the Superior Court of the Province of Quebec, and quoted by H. R. Griffith (*New York State Journal of Medicine*, 1940, 40, 213), is pertinent to this discussion:

"The following propositions are established: (*a*) that the administration of a general anaesthetic is a dangerous thing even to the point of possibly causing the death of the person submitting to it; (*b*) that during the anaesthetic surprises, complications, sudden and unforeseen situations, dangerous to the patient and capable of causing his death, may arise; (*c*) that with the presence of a physician specializing in anaesthesia the life of the patient might almost always be saved when a complication arises during the anaesthetic. . . . The administration of a general anaesthetic is at the same time a science and an art; easy, this science and this art, when all goes well, . . . difficult and exacting of skill and experience when a sudden and dangerous complication arises (these complications vary with the patient and never present exactly the same aspect), being able to cause death very rapidly, if a competent anaesthetist, experienced and knowing how to act quickly in this particular complication, is not ready to cope with it with the discretion, the precision, and ability which can come only with the union of medical science with experience. . . . An anaesthetic agent is a drug which shows its action by certain signs; by these symptoms and signs one knows what is happening to the patient; and to understand these signs and to judge what may arise it is necessary to know medicine. . . . A nurse has not the required medical preparation to be able to cope with an accident during anaesthesia. . . . The surgeon cannot and should not supervise the anaesthesia . . . all his attention and all his faculties should be concentrated on the operation itself without the preoccupation of accessory or extraneous things . . . when a critical situation does arise the surgeon, who should then suspend the operation, comes to assist the anaesthetist, but it is still the latter who remains always the person in charge of the security of the patient."

—I am, etc.,

Goodmayes, Essex, March 2. R. BLAIR GOULD.

Medical Planning Commission

SIR,—I am very glad to see the steady flow of comment and criticism which the Commission has evoked. There is, of course, room for diversity of opinion about its reference and its composition. I myself would much have liked to see more representatives of women and of youth on it, but the problem of selecting the latter is a very difficult one. Young doctors, unless they are predestined medical politicians, are usually too busy making their careers to take much interest in medical affairs, and at present most of them are engaged on something even more important and more urgent. But exception may rightly, I think, be taken to the argument that such a Commission ought to have been set up by some other body, preferably the Government. This point of view has been voiced by Sir Ernest Graham-Little and by Mr. Aleck Bourne,

Of course the former would naturally try to crab anything the Association did: I have always expected carping and ungrateful criticism from him and have never been disappointed.

Mr. Aleck Bourne is in a different category, and I should like to know just what he means by his statement that the chief reason for misgiving about the Commission is that it was "conceived and appointed by a private body which is by no means representative of the whole profession." A *private* body seems to me a somewhat unfortunate term to apply to one which is open to every registered practitioner; which contains a majority of all the practitioners in the country and of every kind of practitioner; and which frames its policy by a constitution which has been declared by good and independent authorities to be a democratic model. As for its representative capacity: what is Mr. Bourne's criterion for this? I suppose he does not insist that for a body to be representative it must include every potential individual. If he does then there is no representative organization of any calling in this country. The trade unions, for example, always consulted by the Government, have a smaller proportion of potential members than we have.

In my more active days the standard complaint was that the B.M.A. did nothing, or was always too late. Now it seems to be suggested that we should leave initiative to the Government. My view is quite contrary. If it be not the duty and the privilege of a body like ours to formulate its views as to the best way of using the profession for the good of the community, I think we had better disband it. The fact of the matter is that many of our members have not a proper pride in their Association, and do not realize what a great national institution it is. In the last war it rendered a service which was unique and which no other body, Government or otherwise, could have rendered, when it successfully undertook to provide all the doctors needed by the Services with due regard for civilian needs. This was handsomely recognized by the Government, not only at the time, but in the present emergency when it gladly accepted the Association as its agent in a similar capacity.

The Commission has undertaken a most honourable and onerous duty, and I hope we shall encourage it in every way we can. When it has finished its labours it will be for the Government to decide how far its report can be used as a basis for action. At any rate we shall have done our best, and I prophesy that we shall be as proud of having done this duty to the best of our ability as we rightly are of our share in the conduct of the medical side of this war and the last.—I am, etc.,

Henley-on-Thames, March 2. ALFRED COX.

SIR,—I have great respect for Dr. Pooler's opinion, but he has misunderstood me. Writing of the Commission I used the phrase "judge and jury" in the colloquial sense, meaning a composite body, in this case not conducting a trial, but making an inquiry, calling witnesses, taking their evidence, weighing it, and issuing a report as to what will be the best and most suitable form of medical service for the State.

This report to be effective must be authoritative and well balanced, and those on whose behalf the inquiry is being made—that is, the people—will look on it as being prejudiced if any one section of the medical services of the country was predominant in the Commission. It must propound a service that will be of intimate import to every member of the community: a service to keep them in health, to cure them if ill. General practitioners have a great responsibility in preparing their evidence and ample opportunity to present it.

If the report is, before publication, circulated to the Divisions for their consideration the great majority of those discussing it would be general practitioners and they would have an opportunity seldom granted to witnesses in such a case.—I am, etc.,

Westbury, Wilts, March 9. CHARLES E. S. FLEMMING.

SIR,—The letter of Lieut.-Colonel C. J. Stocker in your issue of February 22 (p. 296) merits the careful consideration of every member of the medical profession and more especially of the members of the B.M.A.

To me, as to him and to many other doctors, the proposal of the B.M.A. to set up a Commission to settle our future has come as a shock; and the composition of the Commission gave me a still greater shock, composed for the most part, as it is, of what Colonel Stocker aptly calls "the usual medical oligarchs," with an entirely inadequate representation of the general practitioner and practically no representation of the rural general practitioner.

As a member of the B.M.A. of over forty years' standing, a member of the representative body for several years, and a member of Council, I have some right to speak for the general practitioner in Northern Ireland, and I believe that the present policy of the Association, if persisted in, will disrupt the profession and the Association. From my own knowledge I can confirm Colonel Stocker's statement that "there is a growing opposition to B.M.A. methods both within the fold and outside it." Whilst I hold my own very definite opinion as to necessary reforms in the methods and constitution of the Association if it is adequately to represent the views and protect the interests of the largely inarticulate majority of the profession, I fully agree with him that "it is high time that an 'official' opposition should be organized."

The Medical Planning Commission, formed as it was in a hole-and-corner manner, has not the confidence of the bulk of the profession who had no say in the choice of its personnel, and it should be dropped if worse is not to befall.—I am, etc.,

Belfast, Feb. 25. W. LYLE.

Value of Raw Greenstuff

SIR,—Writing on the second day of March, I am reminded of the passing of February, "the month of fevers," with all its menace. It is the month of fevers because it is so long since the spring flush of grass in the previous year gave health and vigour to the animals, and to mankind that consumed their products. By February the protective store is well-nigh exhausted.

At this time when the supplies of food are altered and in some ways lessened there is need to give attention to the use, now in this springtime of all others, of fresh green leaves which a man may himself use—to wit, such as dandelion leaves, watercress, mustard and cress, chives, chervil, chicory, fennel, celery, celeriac. Eggs from hens upon grass are in short supply. Milk for adults may be less plentiful as pasture lands are ploughed. Fresh liver and kidney and many other indirect sources of the protective qualities of food are hard to come by—the more therefore the need to take them direct from their source. The animals do: "These wait all upon Thee that Thou mayest give them their meat in due season." Now is the due season, and, to put it simply, a far wider use of raw greenstuff—say, a leaf or two eaten with each piece of bread and butter—will make next February less a month of fevers than usual, despite Herr Hitler and all his works.

Oranges are in short supply and often have lost much vitamin C in storage. A swede or turnip, in which a hollow the size of an egg is made and filled with honey or brown sugar, will yield a juice not only full of "C" but very acceptable to little children.—I am, etc.,

Holmes Chapel, March 2. LIONEL JAS. PICTON.

Calcium Requirements and Fortified Bread

SIR,—With reference to the Government's decision to fortify bread with calcium it is stated in your leader of February 22 (p. 281) that "the amount and the nature of the calcium salt to be added to bread are still not settled." In your leader of July 27, 1940, it was suggested, however, that the proposed addition would, on the average consumption of bread, amount to 200 mg. of calcium daily. If amounts of this order are under consideration, and it is accepted that calcium as carbonate is utilizable, the intake of calcium from water supplies appears worthy of notice.

In normal times, when a generous dietary including dairy products and vegetables afforded an ample supply of calcium in suitable combinations, it seemed that drinking-water was an unimportant source of calcium. In the light of the opinions expressed in recent articles on calcium requirements this view may, however, now merit reconsideration. The calcium content of water supplies varies widely. It is practically *nil* in areas where the water is derived from upland sources (mostly

in Scotland, Wales, and the North of England), but in other areas (mostly in England) it exceeds 400 mg., and may even be 800 mg., per gallon. Thus Loch Katrine water contains no more than 7 mg. of calcium per gallon, and the average of upland waters is of the order of 40 mg. per gallon. On the other hand, the average calcium content of hard waters derived from the chalk is approximately 450 mg. per gallon and the greater part of the calcium is present as bicarbonate. Assuming the average daily consumption of water in one way or another is three-quarters of a gallon, over 300 mg. of calcium will thus be regularly supplied in most hard-water areas. This is not an insignificant proportion of the estimated daily requirement, and it exceeds the amount (200 mg.) mentioned above as the proposed addition to bread. In such hard-water areas softening—that is, partial removal of calcium—is practised at a few waterworks, sometimes under statutory obligation, and many households are equipped with domestic water softeners.

In view of these various considerations it is suggested that calcium addition to bread might be unnecessary or less important in hard-water areas than in those supplied from upland sources. Also, the advisability, from the dietetic standpoint of removing calcium from drinking-water by softening processes may be questionable at the present time.—I am, etc.,

London, March 4. E. V. SUCKLING.

Calcium Requirement

SIR,—There are some points in the discussions on calcium requirements in the *Journal* of February 22 which merit close consideration. In dealing with the first of these I employ figures quoted by Prof. Cathcart in his Oliver-Sharpey Lectures (*Lancet*, March, 1940, pp. 533 and 586), in which, it may be said in passing, will be found also pertinent criticism of calcium standard formulation, including the remark that "our knowledge of calcium needs is strikingly elementary." Sherman laid down a standard requirement for calcium on the basis of ninety-seven experiments collected from the literature, and found the mean value of the average intake to be 0.45 gramme. In these ninety-seven experiments the level at which equilibrium was obtained varied in individual subjects from 0.27 gramme to 0.82 gramme a day. Leitch, from her statistical study of calcium balance experiments in the literature, concluded that the daily calcium requirement for an adult is reached with an intake of 0.55 gramme; but that positive balances occurred with an intake as low as 0.15 gramme and negative balances with intakes as high as 0.7 gramme.

I do not enter upon a discussion of the significance of the fewness of the cases employed as the basis of computation of these standards and of the lack of evidence that such cases are a true sample of the adult population or of the warrantability of the addition of as much as 50%, to the standard as a "safety factor." I confine myself to a consideration of the possible meaning of the groups of extreme cases at either end of the frequency curve. Is it not a reasonable interpretation of their existence to suggest that they are significant of something very abnormal either in the observational methods employed or in the physiology and metabolism of the subjects observed? It seems, indeed, probable that while a close and detailed study of these might reveal new and unexpected factors influencing metabolism, their inclusion in an "average" or "mean" must detract from any value such a conception may be supposed to possess in the present circumstances. Would it not be more logical in such cases to employ the "mode"—that is, the most frequently obtained result in the series—as the standard of calcium requirement, on the analogy of majority rule in political and other spheres?

As regards a second point, if the standards of calcium requirement proposed are inaccurate, as undoubtedly they are, the figures based on them, alleging to show the amount of calcium deficiency in the community, must be even more fallacious. Again, the amount of calcium and other dietary constituents present in vegetable foodstuffs (as Prof. Cathcart points out) varies with the season, type of fertilizer used, type of soil, parts utilized, locality where grown, variety of plant, and the like within quite wide limits. What guarantee is there therefore that, in dietary surveys, the amount of calcium allocated to an individual diet from a table of analysis from a relatively small series of food materials collected most often from a limited area corresponds with the true state of affairs?

Finally, much, indeed it would seem all, importance is attached to the quantity of calcium in a diet. But calcium, as the sulphate or silicate, though appearing quantitatively as such in a chemical analysis, would not be the metabolic equivalent of the same amount of calcium in the form in which it occurs in homologous milk. These are extreme instances, but calcium, as a supplement, is often supplied as compounds of an intermediate character, and especially as the carbonate. In this context it may be recalled that the routine method of producing rickets in experimental animals is by means of a diet rich in calcium carbonate, a procedure which inactivates the phosphate of the diet. The addition of calcium carbonate, in less but still considerable quantity, produces, paradoxically, a deficiency of available calcium and thus brings about osteoporosis. Calcium salts of the strong acids, such as the chloride, produce acidosis and osteoporosis. The effect of quality, therefore, of calcium in a diet, and especially in dietary supplements, by its influence on availability, actually exceeds in its importance on metabolism that exerted by quantity.—I am, etc.,

Aberdeen, March 1. J. P. MCGOWAN.

SIR,—Much correspondence has recently appeared in these columns as the result of a recent paper in which my name appeared as a part author, and I should like to make use of a little space which might help to clarify the position.

It will be understood that I can only write of the experiments in which I participated some four years ago on patients who were admitted to hospital and kept in bed during the period of the experiment. In part due to this, constipation did occur, and is thus a contributory cause of the shift of Ca from excretion in the faeces to urine—a very unusual feature. This shift might also be aided by the difficulty of varying the dietary Ca and at the same time keeping protein, fat, carbohydrate, and other factors constant. I achieved this by use of calcium saccharate, which was thought to be of high Ca availability—a fact borne out by the results, the saccharic acid radical probably being metabolized.

The main aim of the work, as I understood it at the time, was to ascertain the effect of Ca and other variables upon hypertension rather than optimal Ca requirement for healthy people.

From the results published it would appear that Sherman's minimal requirement of 0.45 gramme a day is confirmed, and since the patients were recumbent they would thus have a basal metabolic rate of 0.6 to 0.8 of that of an ambulant person; thus the Ca needs of the latter would be about 0.5 to 0.75 gramme a day, taking metabolic rate into account. Due to the immobilization of Ca by phytic acid, the actual intake would probably need to be more than this, being still higher in pregnancy and lactation.

It is possible that the same conditions may apply to the results obtained since I left Liverpool in 1938; I cannot say, but I do know that at that time the hospital was not equipped for animal work, although it was a future development.—I am, etc.,

G. V. JAMES, M.Sc., Ph.D.,
Welwyn Garden City, March 6. Major, R.A.M.C.

Royal College of Surgeons Council Elections

SIR,—I have recently received a communication from the Secretary of the Royal College of Surgeons of England in which personal canvassing by candidates for a place on the Council is strongly deprecated. Surely the Fellows of the College have sufficient intelligence and judgment to decide on their own response to a personal canvass without any such official pronouncement. Individual voters have in the past expressed in the columns of the medical press their distaste for the personal canvass. The public proclamation of these hypersensitive protestants savours of exhibitionism, or at least a desire that the world shall know the exquisite quality of their virtue. Besides, there is always the waste-paper basket.

Should the Olympic frown of the Council prove effective in suppressing the personal appeal of frank canvassing (an appeal which is a feature of all political appointments, and regarded as embodying the essential principles of democracy),

what measures are contemplated to deal drastically with privileged bodies like the teaching hospitals, especially those what cater for Fellowship candidates by special courses? Not to be overlooked is that powerful caucus, the Surgical Club, who exercise their collective power to influence electors as effectively as do other "clubs"—Buffaloes, Rechabites, *et hoc genus omne*. At the first warning of an impending election these organizations go into secret session and agree on a mass attack in favour of their chosen one. Against the momentum of these exclusive bodies, what weapon shall the candidate use whose origin is lost in the obscurity of some small or even large non-teaching hospital? His reputation may be international, his pioneer work universally appreciated; to him there remains only the personal canvass of the more liberal-minded Fellows, who also have a right to representation on the Council.

Let all canvassing be abolished, or leave the field open in harmony with the basic principles of democracy.—I am, etc.,

London, W.1, March 6. H. H. GREENWOOD, F.R.C.S.

The Services

Colonel (Temporary Brigadier) J. A. Manifold, D.S.O., late R.A.M.C., has been appointed a Deputy Director of Medical Services and has been granted the acting rank of Major-General.

Universities and Colleges

UNIVERSITY OF OXFORD

The Dr. John Radcliffe Prizes have been awarded to J. M. Walker, G. A. Neligan, and M. Weatherall.

UNIVERSITY OF CAMBRIDGE

The Raymond Horton-Smith Prize for 1939–40 for the best M.D. thesis during the academical year has been awarded to O. A. Trowell, M.A., M.D., St. John's College; *proxime accessit*, G. I. Watson, M.A., M.D., Corpus Christi College.

The following have been examined and approved for the degree of M.Chir.: G. Blackburn, R. C. F. Catterall, J. S. Ellis, C. G. Rob.

UNIVERSITY OF LONDON

J. H. Gray, M.D., B.S.Adelaide, has been appointed from May 1, 1941, to the University Chair of Anatomy tenable at St. Mary's Hospital Medical School. Since 1937 he has been senior demonstrator in anatomy at University College.

The title of Professor of Dental Surgery has been conferred on E. C. Sprawson, *M.C.*, D.Sc., M.R.C.S., L.D.S. R.C.S., in respect of his post held at the London Hospital Medical College.

A Board of Studies in Pathology has been instituted within the purview of the Faculty of Medicine.

The degree of D.Sc. has been conferred on P. A. I. Gorer, an internal student, of Guy's Hospital Medical School; D. W. W Henderson, an internal student, of the Lister Institute of Preventive Medicine; and R. W. Haines, an internal student of St. Thomas's Hospital Medical School.

The following awards have been made: Chester Beatty Scholarship, T. A. Watson, M.B., Ch.B.; William Julius Mickle Fellowship, C. K. Hallpike, M.B., B.S., M.R.C.P., F.R.C.S

WESTMINSTER HOSPITAL MEDICAL SCHOOL

On May 8 and 9 there will be held an entrance scholarship examination upon the result of which there are offered for award four scholarships each to the value of £75. The examination consists of papers in chemistry and physics, and English essay; the closing date is April 23. Further particulars can be obtained from the Secretary, Westminster Hospital Medical School, 17, Horseferry Road, S.W.1.

Obituary

THE LATE PROF. WILLIAM BULLOCH

W. E. H. writes from Horncastle: Prof. Turnbull in his excellent tribute to the late Prof. William Bulloch shows convincingly Bulloch's profound knowledge of bacteriology and pathology. May I, who, like Bulloch, sat under that inspiring teacher of pathology—D. J. Hamilton, Regius Professor of Pathology in the University of Aberdeen—add a personal note? As Prof. Turnbull so justly writes: "Bulloch had a great sense of humour, was an inimitable raconteur, and inherently sociable." At the B.M.A. Annual Meeting at Oxford in 1904 the Pathology Section under Ainley Walker was a very strong attraction, for the main theme was immunity, and eminent authorities, such as Wright and Noguchi, were taking part. In the evenings Bulloch was the attraction as his friends gathered round him to hear his brilliant talk, so pithy and to the point. At the opening session on immunity Wright led off with: "It is an infirmity of the human mind that it demands an explanation before it has assorted the facts." He next proceeded to write on the blackboard the then mystic word "opsonin." He was followed by Bulloch, whose opening sentence was also an arresting one. "The task allotted to me," he said, "is to state what is fact and what is fancy in our researches into immunity. We have reached the stage when we marshal our facts and court-martial our fictions." The whole discussion was on a high plane, and Bulloch that day shone among the Olympians.

News has been received of the death of Dr. HANS WILDBOLZ, professor of urological diagnosis at the Berne medical faculty, and chief of the Insel Hospital at Berne, aged 68. He had been an honorary member of the Section of Urology of the Royal Society of Medicine since 1928. His name has been given to a reaction in tuberculosis following intracutaneous injection of the patient's urine or blood.

At the memorial service for Sir Frederick Banting in St. Martin-in-the-Fields on March 5 the Council of the British Medical Association was represented by Mr. W. McAdam Eccles, consulting surgeon to St. Bartholomew's Hospital.

Medical Notes in Parliament

Rockefeller Clinical Studentships in America

Prof. A. V. HILL asked on March 6 whether the Minister of Health knew that an offer had been received from the Rockefeller Foundation in New York to undertake and provide for the clinical training and maintenance of selected British medical students in a number of medical schools in the United States of America and Canada. He asked if Mr. Brown would arrange for all facilities and encouragement to be given for carrying out the scheme. Mr. ERNEST BROWN said he was aware of the offer and desired to express his very sincere appreciation of this sign of practical help and sympathy on the part of the Foundation and of the medical schools in America. He would certainly do all he could to further this scheme. A committee had been set up in this country under the chairmanship of the vice-chancellor of Manchester University to select the students. The first group would leave for America as soon as possible. The General Medical Council, the licensing bodies, and the universities were all in agreement on the advantages of the scheme. He was sure that when the students returned to this country their experience would be of great value, and he hoped that this plan might further strengthen the close co-operation in medicine and public health between Great Britain, the United States, and Canada.

Sir FRANCIS FREMANTLE asked whether Mr. Brown recognized that some of the best students would be reluctant to

leave this country and go to a safer country during the war. In Sir Francis's opinion it was necessary that they should avail themselves of this opportunity. He asked Mr. Brown to encourage them to avail themselves of it as a patriotic duty. Mr. BROWN said the Government understood that these young men would have such feelings. They could be assured that by going and continuing their training in America they would undertake the best form of national service.

Family Allowances

The BISHOP OF WINCHESTER, in the House of Lords on March 5, moved a motion advocating family allowances to prevent the increased cost of living from injuring families with dependent children. He recalled that he raised this subject in 1938, when the Government found itself unable to appoint a committee on it. He now said that children had to bear the heaviest burden of poverty, which was largely confined to families in which there were three or more children and in which the wage-earner was poorly paid. This had been accentuated lately by war conditions. If these children were neglected they would grow up anaemic, unhealthy citizens. If a man was in work he had no family allowance, but if he was out of work the Public Assistance Board made an allowance for the children he had.

Viscount SAMUEL said the case presented was overwhelming. An immense number of the children of the country had too little food or food of bad quality. Their health and strength were impaired. In this country 1,250,000 children belonged to families where there were four, five, or six children. Nemesis was now upon the country because, owing to the strain on families combined with the invention of means of birth control, there had been a catastrophic fall in the birth rate. The House would remember a cogent speech made on that subject by Lord Dawson of Penn during a debate in June, 1939. The Metropolitan Police and some of the most enlightened industrial firms had introduced family allowances, in each case with complete success. Lord STAMP suggested that wage increases based on the cost of living should be measured by reference to an average family of two children and recognition of the needs of additional children.

Lord MOYNE said that a year or two ago the report of the Unemployment Insurance Statutory Committee showed that when weekly payment was based on a subsistence level, the wage level earned for large families had been dangerously depressed below the absolute necessities of life. Family allowances were only one method of dealing with this intricate problem. It would be out of the question to ask the Chancellor of the Exchequer to assume the burden of family allowances at the present time. There was much to be said for the view that Parliament should begin by methods of direct assistance such as the provision of pure milk, which could not fail to go to the benefit of the children. One-fifth of the milk drunk in this country was now going through the channel of the milk scheme. He found no hostility shown by the Chancellor of the Exchequer to the idea of family allowances as part of post-war reconstruction if an acceptable scheme could be worked out. But the Chancellor made it clear that he could not afford the present system of subsidizing the necessities of life and at the same time provide for family allowances. Mr. Greenwood, who was charged with planning the post-war system, was giving consideration to the question.

Diphtheria Immunization in Scotland

On March 4 Mr. LEACH inquired why the subcommittee which recently reported on the practical application of diphtheria immunization in Scotland, and ascertained the number of children immunized in Edinburgh and other particulars concerning diphtheria immunization in that city, did not also obtain details, known to be available in the medical officer's office, of the number of cases of diphtheria and deaths from that disease in immunized and non-immunized children. Mr. JOHNSTON replied that in Edinburgh much of the diphtheria immunization had been done by general practitioners. Accurate information whether individual children were or were not immunized was not available either to the Public Health Department or to hospitals where cases of diphtheria were treated. Such particulars as were available were approximate only, and were, therefore, not regarded by the Scientific Advisory Committee as appropriate for inclusion in their report.

Advancing the Clock

Mr HERBERT MORRISON said on March 4 that the addition during the summer months of an extra hour's daylight in the evening would be advantageous to the war effort in many ways. In many factories it would enable two shifts to be worked in daylight. The conclusion of the Government was that, provided the period during which the changed time operated was limited to mitigate the agricultural disadvantages, the scheme ought to be adopted. He accordingly proposed to make a Defence Regulation advancing the clock by another hour from the night of Saturday, May 3, to the night of Saturday, August 9. The House of Commons would have an opportunity to debate this Regulation.

Distribution of Medical Man-power

Mr BROWN told Mr. Mander on March 6 that recommendations would shortly be published from the committee presided over by Sir Arthur Robinson to consider the steps necessary to secure a proper allocation of the available medical manpower between civilian and medical services. Mr. Brown added that in conjunction with the other Ministers concerned he was taking action on the recommendations. The committee sat for seven days and heard seventeen witnesses, of whom twelve were medical. As the inquiry was urgent and confidential the committee only called for such evidence from Government Departments and public bodies as it required to supplement the considerable knowledge of the subject possessed by its members. He would be glad to seek further competent advice if the recommendations proved that to be necessary. The committee's deliberations were confidential.

Sir LEONARD LYLE inquired on March 5 if Mr. Brown was aware of the shortage of doctors in many rural districts, especially when these were overcrowded with evacuees of all sorts. He asked what steps were taken to ensure that the younger doctors were not called up before the real need began for the use of their services by the Army. Miss HORSBRUGH replied that Mr. Brown was aware of the shortage of doctors in some rural areas and appreciated the difficulties. The measures which he was taking in conjunction with the Service Ministers and the Secretary of State for Scotland on the recommendation of Sir Arthur Robinson's committee were designed to reduce to a minimum the number of doctors to be called up from private practice. In selecting the individual doctors for commission the Central Medical War Committee and its local committees gave full weight to the special needs of the reception areas. A definite scheme was to be arranged to ration doctors both for the civilian population and the Army. The matter was being gone into and the doctors who might have been called up were remaining in their civilian practices. Answering Sir Francis Fremantle, Miss Horsbrugh said she could not give the date when the priority committee would get to work.

Casualty Services: Cardiff's Example

Dr. MORGAN asked on March 6 whether the attention of Mr. Brown had been called to the arrangements in Cardiff, in which every general practitioner had been provided with adequate equipment for dealing with air-raid casualties at the site of incidents, and had been informed exactly how the air-raid precautions services were organized and the part which he would have to play in them. He asked Mr. Brown to compel the making of similar arrangements in other towns. Mr. BROWN said he had received a report on the arrangements at Cardiff. While he approved them generally he was asking his medical officers to communicate with the responsible local officers on certain aspects of the scheme which required further consideration. His medical officers were constantly in touch with medical officers of health on the most suitable arrangements for utilizing the services of practitioners in the area. These must necessarily vary in detail according to local conditions.

Dr. MORGAN suggested that in many large towns a number of general practitioners had been given no opportunity to

acquaint themselves with the various phases of air-raid precautions work, or with the persons, the aid posts, etc., with which they would be required to co-operate in case of emergency. Mr. BROWN said medical officers of health were asked last year to make plans for reinforcing the hospitals and first-aid posts, in case of emergency, by practitioners not officially attached to those services. They had generally got into touch with the profession in their areas, by calling meetings or otherwise, in order to familiarize them with the services.

Trichiniasis

Dr. MORGAN referred on March 6 to the recent occurrence of cases of trichiniasis in parts of Great Britain and the identification of pork and pork products as their cause. He urged the compulsory heating and cooking of all such products, especially those used in the making of sausages. Mr. BROWN replied that investigations were in progress with regard to these occurrences. By wireless and in the Press it had been pointed out that provided pig meat was thoroughly cooked no risk would be run. He did not think it necessary to order the compulsory heating and cooking of all pig products.

London's Ambulance Service

On March 6 Mr. BARTLETT inquired how many ambulance stations in the London area were fully staffed on the scale laid down at the beginning of the war; and how many resignations and enlistments took place in the last six months. Mr. BROWN said in reply that the establishment of the London auxiliary ambulance service was not laid down in terms of stations, the staff of which could vary according to circumstances. The total staff of the service was somewhat below the authorized strength, but had proved adequate to meet the calls made on it. In the six months September, 1940, to February, 1941, resignations numbered 1,268 whole-time and 357 part-time staff, while enlistments numbered 608 and 275 respectively. Mr. Brown paid tribute to the courage and devotion shown by the ambulance staffs in maintaining this service.

Physiological Problems of Flying

Introducing the Air Estimates on March 11, Sir ARCHIBALD SINCLAIR said special attention was being paid to the problem of cold, to the supply of oxygen at high altitudes, and to night vision. The development of aircraft tended toward flying at great heights, and research was continuous to find a solution to the physiological problems involved. The problem of cold was being tackled by the sealing up—a difficult technical problem in a fighting aircraft—and the heating of cabins, and by provision of equipment, boots, gloves, helmets, and underclothing of special design. The psychological care of pilots was not less important. The early detection of signs of flying strain formed an important part of the duties of medical officers of the Air Force. The fighting spirit of the pilots was so strong that unless they were closely watched they kept on flying long after they should have been rested from operations. The doctor's duty was to catch them in time so that the squadron or station commander could make them rest. Good results had been achieved. The incidence of flying strain had been considerably lower than was expected before the war. The Ministry's four orthopaedic centres were second to none in the country to-day. Behind them were rehabilitation centres situated in the healthiest parts of the country, at which the most up-to-date methods were applied to secure recovery as quickly as possible. In addition, centres with the most modern forms of treatment for severe burns had been established.

Doctors' Duties in Invasion

Mr. GROVES inquired on March 11 whether any comprehensive scheme had been formulated and notified to all civilian members of the medical profession whereby their services were available and their precise duties known in case of emergency, whether due to air raids or invasion. Mr. BROWN answered that it was obviously impossible to assign precise duties in advance to every civilian doctor. The plans for reinforcing the hospital and first-aid post services in the event of military operations in this country were, as announced in the medical press last month, being worked out in conjunction with the appropriate R.A.M.C. officers and also, in order to secure consultation with practical medical bodies, with the secretaries of Local Medical War Committees. He had every reason to believe that this procedure would produce satisfactory and efficient schemes.

Shelter Conditions in Provinces.—Miss HORSBRUGH stated on March 11 that the attention of Mr. Ernest Brown had been called to Lord Horder's report on March 4 about children living in public shelters in the Provinces. Mr. Brown had recently inspected some of the shelters Lord Horder had in mind, and had under active consideration proposals for dealing with the matter.

Notes in Brief

Of the 42,319 claims for injury allowances up to February 1, 1941, from civil defence volunteers and other civilians, 3,438 were rejected, and of the 5,483 claims for pension 615 were rejected.

Medical News

The next meeting of the Association of Industrial Medical Officers will be held on Saturday, March 22, at 3 p.m., at the Engineers' Club, Manchester. The public business will begin at 3.45 p.m., the subject for discussion being "Toxic Substances in Industry," opened by Dr. S. A. Henry. Dr. M. W. Goldblatt will discuss the hazards of the chemical industry, Dr. A. J. Amor those of the welding industry, and Dr. A. L. Leigh Silver various health problems in filling factories. The discussion will be followed by a dinner at the Engineers' Club at 6.15 p.m.

Because of the frequency with which hospitals are bombed from the air, a fleet of twenty-five mobile *x*-ray plants, each capable of the most urgent work of a hospital radiographic department, is being built by the War Organization of the British Red Cross. Generally speaking, these units are built to the Society's design—a design which has stood the test of experience over a long period of time. They will be posted, in collaboration with the Ministry of Health, throughout the country, in districts where the Ministry thinks they will serve a useful purpose. All the usual accessories are housed in the vans, and the units are self-contained, being built to generate their own power.

The board of management and the medical staff of the Hospital for Sick Children, Great Ormond Street, are anxious to offer medical men and women from over-seas the opportunity of visiting the hospital during their stay in this country. The hospital block, the second section of the rebuilding scheme, was completed just before the war, and contains many interesting features in design and equipment, the product of the experience of the medical, nursing, and lay staff during the past quarter of a century. Doctors and nurses now in England, particularly those interested in the treatment and care of sick children, will be welcomed.

The Bombay Medical Council at a meeting last September resolved that "in the absence of a common Indian language medical education of the Western type should for the time being be imparted through English as is done at present." Reference was made to the impending retirement of General Buckley, who has been President of the Council for nearly four years, and a unanimous resolution was passed expressing appreciation of the valuable services he has rendered to the profession, and particularly to the Council, during that period.

The Royal Northern Hospital, Holloway, has received, through Mrs. Wales Latham of New York and Mrs. Edward Murrow of London, 30,000 dollars for six months' maintenance of the operating theatres and *x*-ray department. The gift has been received with this message: "Delighted that 'Bundles for Britain' and its 800 branches can share in your courageous work through the sympathy and generosity of the American people."

The New South Wales Health Department proposes to appoint at least 10,000 residents, both male and female, between the ages of 18 and 60, to participate in a blood transfusion scheme to provide a twenty-four-hour service of blood donors to hospitals and a supply of blood for transfusions in any emergency.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics of the British Isles during the week ended February 15, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included); (b) London (administrative county); (c) Scotland; (d) Eire; (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each heading of disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	(b)	(c)	(d)	(e)	1940 (corresponding Week) (a)	(b)	(c)	(d)	(e)

* Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

Measles, whooping-cough, diphtheria, pneumonia, cerebrospinal fever, and dysentery have increased in incidence during the week. In Scotland notifications remained at approximately the same level, with the exception of whooping-cough, which showed an appreciable increase although deaths were fewer.

Cerebrospinal Fever

Cerebrospinal fever has appeared in fewer localities than last year—approximately two-thirds of the administrative health areas as against nearly five-sixths in the corresponding week of last year. Except for the highly industrialized centres of Lancashire and the West Riding of Yorkshire, local prevalences have nowhere reached the dignity of epidemics. The chief centres of the disease at present are Lancashire 57; West Riding of Yorkshire 28; London 26; Middlesex and Warwick 17 each; Chester 16; Glamorgan 15; Durham, Essex, and Surrey 14 each; Southampton 13; Stafford 11; Devon 10. Notifications for the week ending March 1 numbered 460. In Scotland just under one-half of the counties and burghs are affected, notably the counties of Dumfries 4; Ayr, Fife, and Lanark 3 each; and the burghs of Glasgow 25, Edinburgh 12, Ayr and Rutherglen 3 each.

Dysentery

Although the incidence of dysentery has been mounting in recent weeks it remains a comparatively infrequent disease, and at present has appeared in only fifteen of the administrative areas, three of which account for over three-fifths of the total, while only single cases were recorded in no more than a third of the areas. It is probable that the notified cases are an underestimate of the real incidence of the disease, as single cases of the prevailing mild Sonne type are readily overlooked. The areas chiefly affected were Lancaster 49, Essex 28, Bedford 27, London 11, Northampton 10, Kent 6. In Scotland the notifications were: Fife 3, Argyll 2, Dumbarton and Stirling 1 each, and in the burghs of Edinburgh 9, Aberdeen 5, Dundee and Glasgow 4 each, Paisley 1.

Influenza for Week Ending March 1

In the week ended March 1 267 deaths were ascribed to influenza in the great towns, 47 fewer than in the previous week. The age distribution continues to be normal: 5.7% only of the deaths were at ages under 25 and 55.8% at ages

Total of Influenza Deaths and Deaths in Age Groups in 126 Great Towns for Week Ending March 1

All Ages	A Under 1 year	B 1-5	C 5-15	D 15-25	E 25-35	F 35-45	G 45-55	H 55-65	I 65-75	J 75 and over
267	8	—	2	11	6	14	34	43	70	79

Regional Totals of Influenza Deaths for Week Ending March 1

South-Eastern Area:			Midland Area	54
Greater London	79		Eastern Area	5
Rest of S.E.	16	= 95	South-Western Area	7
Northern Area		102	Wales and Monmouthshire	14

Total for 126 Great Towns, including the Outer Ring 265

over 65. In the County of London the deaths have decreased from 26 to 20. The proportion of total deaths coming from the South-Eastern Area remains almost the same as last week—35.5%. This is the second week of decline in total mortality, and it is now improbable that this winter's experience will be as bad as that of 1940, when the epidemic was not very severe.

As the appeal of the Spanish Government for general vaccination has had little effect, the following method has been employed. Food cards will in future only be given on presentation of a vaccination certificate, and a vaccination department will be established close to the office for distribution of food cards where vaccination can be performed gratuitously.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Mediseera Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Wild Plants as Sources of Vitamin C

Dr. W. J. BURNS SELKIRK (Birmingham) asks whether there is any objection to recommending the young leaves of the hawthorn for eating in place of fresh vegetables this year. He writes: Nasturtium leaves, I believe, can be eaten freely "as salad" component. It would also be interesting if you could publish from some Finnish source the recipe for making a conserve of wild rose hips, which, I understand, the Finns make and use through the winter, the hips being very rich in vitamin C. What book would you recommend dealing with the use of wild herbs? No doubt past generations of country folk were in the habit of using various herbs in the spring after winter deprivation of sources of vitamin C. The field dandelion, as used in salads by the French peasants, is one at least.

Coley's Fluid

Dr. W. R. STEPHEN (Lodge, near Wrexham) writes: Can Coley's fluid be used while the patient is still at work or in such a manner that he is off work as little as possible? I should be grateful for any advice.

Intestinal Flatulence in the Aged

"R. S." writes: I should be grateful for suggestions about the treatment of a case of intestinal flatulence, distressing to the patient. Liquid paraffin and pil. alophen have been prescribed to regulate the bowels, and carminatives have been administered. The patient is 78 years of age and of active habits.

Dysmenorrhoea

Mr. A. J. HOBSON, F.R.C.S. (Wimbledon, S.W.20), writes: I would like to reply to Dr. D. C. Miln (February 22, p. 304) under the headings he suggests. (1) The mixture should be commenced about a week before the period is expected and continued through the period itself. (2) I have to confess that the cases in which I have tried out this mixture have been chiefly among my friends and relatives, people whose intake of vitamin D is probably adequate. In these cases I have been extremely satisfied with the success of the prescription. In my hospital work, dealing with patients of a less sufficient dietary level and chiefly cases of delayed bony union, I give vitamin D and rely on injections of calcium Sandoz. (3) The rapid benefit I have obtained in cases of really bad chilblains would appear to show a very definite effect on vascular permeability. As to expense, I have no experience at all with national health insurance practice, but as I have yet to find calcium tablets of any use, I think that if more extended use of the mixture I put forward proves its value then a good case could be made out for its employment. Finally, I have always wondered why some young biochemist does not fully investigate calcium balance—intake and excretion—under different diets and treatments.

Dr. GEORGE HALL (Montreal) writes: When gynaecological findings were negative I have used the following recipe over a period of twenty-five years with very pleasing results—namely, saturated solution of pot. iodid. in aqua chlorof., mv, t.i.d., p.c., for two or three months. Tribute is paid to this treatment in his book *The Horse and Buggy Doctor*, by Dr. Arthur E. Hertzler, published by Harper Bros., London and New York. I am of the opinion that the majority of cases are psychological, but pot. iodid. will do the trick.

Treatment of Herpes

Dr. RANDAL A. STEWART (Hampstead, N.W.3) writes: With regard to the treatment of herpes, I have found the old A.C.M. lotion, when swabbed over the lesions three to four times daily, to be particularly effective in drying up the lesion and also in preventing a secondary impetigo. The formula is:

℞	Acetone	ʒij
	Cyllin	mxlviij
	Sp. vin. meth.	ad ʒv

The only disadvantage is that the application is rather painful when applied over large areas. It is very valuable in herpes labialis. The lotion is an excellent one in the preparation of the skin for surgical operations. The acetone has the effect of dissolving grease, thus allowing the disinfectant to act.

LETTERS, NOTES, ETC.

Scabies

Dr. E. A. WELSH (Felton, Morpeth) writes: I was very pleased to see the letter by a practising dermatologist on the subject of scabies. I have seen more of this condition during the past year than in the previous eighteen years I have been in practice. It may not be an infectious disease in the accepted sense, but in the ordinary sense it is the most infectious disease I know. Measles and whooping-cough are now notifiable, and their treatment is easy as compared to scabies. If it continues to increase at its present rate there will soon be few of us not in need of treatment. The impossibility of efficient treatment under adverse conditions and when a whole household has become thoroughly infested is such that some active interest is called for from the public health services.

Green Vegetables

"G. E." writes: As a doctor's wife who reads the *B.M.J.* even more methodically than he himself, may I state that in my opinion your correspondents have not looked at the above question from the woman's point of view. The suggested lower price of vegetables would not popularize them with the poorer members of the community. Even were they to be given away there is so much time and labour involved in cleaning and preparing them that the working-class woman is prejudiced from the start. In homes where a servant is kept there is usually no lack of properly cleaned and cooked green vegetables at meal-times, but the poorer housewife is not paid a wage for this "drudgery." Working-class children would receive ample supplies of these vital foodstuffs were it possible to obtain them in tins, or even packed ready cooked, like fish and chips, in newspapers!

Tourniquet for First Aid

Dr. THOMAS G. OSLER (Watford) writes: I wish to endorse the recent note in your *Journal* (February 15, p. 262) by Captain Farris, R.A.M.C., on a first-aid tourniquet made from strips cut out of discarded motor-car inner tubes, and am interested to note the good results he records. I have recommended for use a similar tourniquet in the Watford Borough A.R.P. casualty services, my pattern being 2 inches broad by 3 feet or 4 feet long, the different lengths being for the upper or the lower limbs respectively. These lengths give the advantage of obtaining obliteration by the pressure of several firmly applied turns as opposed to one or two very tight ones, and this also is an advantage in the gradual loosening of the tourniquet. Two tapes are fastened on to one end and are used for fixing the tourniquet on the limb; a small rubber loop is attached to the other end and serves to hold the tourniquet in a neat rolled-up position ready for immediate use.

Zinc Peroxide for War Wounds

Dr. W. J. BURNS SELKIRK writes with reference to the annotation on this subject (February 2, p. 285): I had a case of cancer of the mouth and pharynx, sloughy, foul, and fetid. The patient refused surgical treatment and I gave him large doses of pot. chlorate. The cancer became clean, lost its fetor, and the patient lost the foul taste from it. Otherwise, of course, the case progressed to a fatal termination.

Corrigendum

Dr. D. FITZGERALD MOORE writes: In my letter (December 14, 1940, p. 848) on nutritional disturbances and optic atrophy the reference to T. Moore in relation to animal experiments and optic atrophy should read L. A. Moore (U.S.A.). I also made the statement that manioc is fairly rich in riboflavin. It is, however, possible that processed manioc such as gari, in common use as a local food, may show a much lessened riboflavin content. It is hoped to get more definite information on this point in due course.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MARCH 15 1941

SCHEME FOR STATE MEDICAL SERVICE

BY
S. TERRY PYBUS, M.D.

It is now generally agreed that in the near future we shall have some form of State Medical Service: I venture, therefore, to outline very generally my scheme for a complete service. Some may consider it too ambitious, but I contend that, when organizing so important a service and one which must make such great changes in our profession, we should do the job thoroughly at the start, rather than by a series of half-measures and makeshifts. Furthermore, only by bringing all medical services into one complete State organization can we attain the greatest efficiency and economy.

The tendency for some years has been for medical practice to be divided into too many separate departments—specialist, general, and panel practice, public health and preventive medicine with its special clinics, school medical service, and so on—many of them administered by such different bodies as the Ministry of Health, the Home Office, the Board of Education, local authorities, etc., each working in its own small sphere with but little attempt at co-operation. I suggest that under the State service all should be administered by one body working under the Ministry of Health, and that at least 50% of the members of this central administrative body should be medical men. I should include every branch of the profession in the State service—panel and private practitioners, consultants and specialists, public health medical officers, and also dental surgeons and nurses—and would take over all clinics—school, ante-natal, tuberculosis, venereal disease, etc.—hospitals—general, isolation, mental, etc.—as well as homes for old people and incurables. This is a very wide scheme, but it is thorough and would provide a medical service second to none.

To start with, the State service would provide medical attention for everyone with an annual income of £500 or less, men, women, and children, with the exception of members of the Army, Navy, or Air Force, who would be looked after by the Service medical staffs. Persons with an income of over £500 a year would have the choice of being attended under the State service at fees to be detailed later, or by any doctors who refused to serve under the State scheme. In time the latter would disappear, and all would enjoy the privileges of the State service. Sickness benefit would not be included in the scheme, but could be provided separately by a pensions department, which would also deal with old age, widows', and other pensions. Approved societies would cease to have any connexion with the State service or with sickness benefit payable by the pensions department. At the change over, wherever possible, doctors would be allowed to remain in the locality where they had previously practised if they so desired, although, in some areas, some redistribution would be necessary to provide adequate medical attention for the population. So far as possible patients would be given free choice of doctor and hospital.

Regionalization

The country would be divided into regions defined by geographical conditions and density of population. The headquarters of each region would be one of the big general hospitals, which would be the centre for the consultant staff of the region and the teaching hospital for medical students and for postgraduate courses. In addition to the clinical staff there would be the regional administrative staff and the regional public health staff (the latter replacing the present county medical officers of health) with offices in or near the hospital.

The regions would be subdivided into areas, each of which would have one of the smaller general hospitals as its centre and its own clinical, administrative, and public health staffs. On the clinical staff would be a full complement of consultants for every branch of medicine and surgery, who could be called in when required by the medical officers of the clinics in the area. There would also be a relief staff of medical officers for the clinics to take duty during vacations, sick leave, or epidemics. All mental and isolation hospitals, maternity homes, homes for incurables and the aged, sanatoria, etc., would be administered by the area administrative staff, who would also be responsible for the organization of all clinics from which the district staff would work.

The areas would be further subdivided into districts, with a clinic as headquarters of each. These clinics would replace the present surgeries, but, unlike the latter, would be equipped with up-to-date apparatus for diagnosis and treatment. They would take over the work of the present school, venereal disease, and ante-natal clinics, the public dispensaries, etc., as well as of general practice. Each would normally cater for about 20,000 inhabitants and would have a staff of from ten to fifteen medical officers; in some country districts a smaller clinic would be desirable. Attached to each clinic would be a small hospital of twenty to fifty beds for emergencies, cases under observation, maternity cases, and those not serious enough to send into the area hospitals or patients too ill to stand the longer journey. The clinic staffs would be encouraged to specialize in medicine, surgery, obstetrics, pathology, etc., according to their tastes and ability, with a view to promotion to the area and regional hospitals as vacancies occurred. Team work would be encouraged so that the patient would receive the best available treatment, but each case would remain under the care of its original medical officer, thus maintaining continuity of treatment from beginning to end. Each medical officer would attend the clinic at his own stated time daily (as our present surgery hours), but there would always be at least one doctor on duty day and night for emergencies. Night and Sunday duty would be taken in rotation, and every medical officer would have one free day each week at least, five weeks' annual vacation, and two weeks' postgraduate leave each year for study at an area or regional hospital. Where the demands of the district justified it, sub-clinics would be provided, which would be well-equipped surgeries where doctors from the clinic would attend at stated hours daily. The clinic medical officers would work in close collaboration with the clinical and administrative staffs of the area. Dental surgeons would be attached to regional, area, and clinic staffs on terms of service similar to those of the medical men, while district nurses would be included in the personnel of the clinics, replacing the present district nursing associations. These nurses would receive an adequate salary and would be given opportunities for promotion to other posts.

Remuneration and Practice Compensation

All newly qualified doctors on joining the service would spend their first two years as house officers at a regional or area hospital or as junior medical officers at a clinic, with a salary of £250 a year; after this they would be appointed to the regular clinic staff. Promotion on the clinic staffs would be by seniority of service; promotion from clinic to area, and later to regional, staffs would be by seniority and ability, for no medical man would be appointed to area or regional staff until he had obtained a higher or additional qualification in his special branch of work. Those wishing to do so could take duty on the administrative instead of the clinical work. Salaries of clinic medical officers would be £500 a year, rising to £1,250; the area staff would have a minimum salary of £750 a year, or the salary they were receiving when promoted from the clinic staff, rising to a maximum of £1,850 a year. The maximum for the senior man of any department of a regional staff would be £2,500 a year. All would contribute to a superannuation fund and would retire on pension, voluntarily at the age of 60 or compulsorily at the age of 65. In the case of retirement owing to ill-health a pension would be given according to the circumstances of the case.

As regards compensation to doctors for the loss of practices for which they had paid large premiums, I suggest that when a doctor gives over his practice to the State and takes a post in the State service the Government should recompense him for his loss of capital. As he would start in the State service with a salary and position in accordance with the years he had been qualified and his ability and would, in addition, be eligible for a pension, I suggest that he be given one year's purchase, based on the figures for the last three years. In the case of practices purchased through insurance companies or finance corporations, the State Medical Service Act must contain a clause whereby the sum to be repaid on the practice being sold to the State must in no instance be greater than the sum given by the State for the practice. This might hit the companies in a few cases, but it would be only fair; they should bear a small loss for the benefit of the State along with those doctors who had paid cash for their practices. I further suggest that instead of paying out the whole of the purchase price immediately, the State should pay it in bonds maturing in from five to twenty-five years, with interest at the rate of 5% per annum. This would spread the cost over a number of years and relieve the financial strain at the start of the scheme, when there would be other expenses, such as the cost of freeing hospitals from debt, equipping clinics, etc.

Financing the Service

The costs of the service would be borne by the Government, and the money raised by taxation and from the fees paid by certain patients. All persons with an income of £250 a year or less would be attended free of charge, either in clinic or hospital. Those with an income of from £250 to £500 would pay a fee of 3s. 6d. per consultation at a clinic, 5s. a visit, and, when in hospital, £1 a week for each £100 of income, plus a small operation fee. Those with an income of over £500 a year (voluntary members) would pay from 5s. to two guineas for a consultation or visit, a hospital fee of from five to twenty guineas a week, with an operation fee of from two to fifty guineas, according to income. Medicine would be supplied free to all with an annual income of £250 or less; prescriptions would be given as under the National Health Insurance Act, and chemists would be paid by the Ministry of Health. Persons with incomes of from £250 to £500 a year would be given a prescription but would pay the chemist themselves, an exception being made perhaps when exceptionally expensive drugs were essential. Voluntary members would pay for all prescriptions dispensed by the pharmacist.

Medical officers of health have been asked (*Circular 2254*) to supply the Ministry of Health with information concerning those men born in the year 1922 or between the years 1908 and 1919 inclusive who have a history of tuberculosis. The information should be supplied on Form T.147 in accordance with the instructions given in an earlier circular (*Journal*, October 12, 1940, p. 501).

MEDICAL BENEFIT IN NEW ZEALAND

It has recently been announced that Mr. Nordmeyer, who succeeded Mr. Fraser as New Zealand Minister of Health on the appointment of the latter as Prime Minister of the Dominion, has declared March 1 of this year as the appointed day for bringing into effect the general medical practitioner service and the hospital out-patient service provided under the Social Security Act of 1938 and its Amending Act passed in September, 1939. He has also stated that the establishment of a free pharmaceutical service may be expected on April 1 next. These announcements are somewhat surprising, though information reaching this country as to the progress of events in this regard during recent months has not been very definite.

In the *Supplement* of March 23, 1940, we gave an account of the then position of the administration of the health provisions of the Social Security Act, recording with satisfaction the acceptance by the Government of the British Medical Association's proposals in regard to maternity benefit and a watchful attitude on the part of the profession as regards hospital in-patient provision, but stating that the New Zealand Branch of the Association was opposed as strongly as ever to the general practitioner service, mainly, but not exclusively, on the ground of the universality of the proposed clientele. It was expected at that time that negotiations might continue in a friendly atmosphere, but it seemed probable that no attempt would be made to establish this part of medical benefit before the end of the war. These hopes have unfortunately now been disappointed, and the Government has decided to attempt to institute this service at once in spite of the opposition or attitude of non-cooperation of the Association.

Under these conditions, and so far as our information extends, it is difficult to see how any satisfactory general practitioner service can come into being. Hitherto the loyalty of members of the profession to the Association and their confidence in the leaders of the New Zealand Branch have been a very marked feature. For example, in their successful opposition to the original proposals for maternity benefit less than thirty practitioners out of well over 800 were willing to accept contracts. It would seem that the number willing to take part in the new service, even should the proportion be larger than that indicated, must be wholely inadequate. During the controversy that preceded the enactment of 1938 it was stated that in such an event the Government would be prepared to invite American *and German* doctors to settle in the Dominion and to place their names on the *Medical Register*. Circumstances have ruled that out, but it is possible that the New Zealand Ministry of Health has decided in some way to exploit the out-patient departments of hospitals to help out an unfortunate situation and justify a deplorable decision. It is to be hoped that the customary loyalty of the profession to its leaders will enable some reasonable change to be brought about.

Correspondence

Public Health Appointments in Wartime

SIR,—As a candidate who was interviewed for the appointment in the Department of Health for Scotland which was referred to in the letter in the *Supplement* of March 1 (p. 25), I should like to make some comments. There is no doubt that persons serving with the Forces are at a disadvantage in regard to these posts, and everyone would welcome the clarification which your correspondents request. But before this is attempted, it ought to be established as a principle that the disadvantage be shared equally by medical officers in the Forces and civilian medical officers. Many medical officers in public appointments are engaged in civil defence work, and it cannot be suggested that they are serving their country in any lesser capacity than those in the Forces. Personally, I am employed in a "front-line" borough, and although I am registered for military service and should welcome the opportunity to be in the Forces, the local authority has made representations to the Local Emergency Committee for my exemption and these have been accepted.

To make all public appointments temporary would transfer the disadvantage entirely to the civilian medical officers. The posts of most medical officers with the Forces are held open for them for the duration of the war, but if a civilian medical officer leaves a permanent appointment for a temporary one he may find himself unemployed at the end of the war or may be obliged to accept a post inferior to that which he originally held. I hope that these considerations will be borne in mind in any attempt to correct the present injustice to practitioners in the Forces.—I am, etc.,

March 3. DEPUTY M O H.

British Medical Association

Diary of Central Meetings

APRIL

2 Wed. Industrial Health, 2 p.m.

Branch and Division Meetings to be Held

ABERDEEN BRANCH: CITY OF ABERDEEN DIVISION.—At Forresterhill, Aberdeen, Thursday, March 20, 8.30 p.m. Prof. D. Baird, "The Problem of the High Stillbirth and Neonatal Death Rates." Members of the Aberdeen and Kincardine Counties Division are invited to attend.

GLASGOW AND WEST OF SCOTLAND BRANCH.—At 39, Elmbank Crescent, Glasgow, Sunday, March 16, 3 p.m. First of a series of three lectures by Drs. J. Nairn Hay and G. L. Pillans, "Recent Developments in the Diagnosis and Treatment of War Gas Casualties." All practitioners in the area of the Branch are invited to attend.

METROPOLITAN COUNTIES BRANCH: CITY DIVISION.—At B.M.A. House, Tavistock Square, W.C.1, Wednesday, March 19, 2.30 p.m. Papers by Prof. J. C. Drummond, "Nutrition in Time of War"; Prof. Major Greenwood, "Some Epidemiological Problems of the Air War"; Dr. J. C. Spence (Newcastle-upon-Tyne), "Clinical Aspects of Nutrition." All members and doctors in the area of the Branch are invited to attend.

NORTH OF ENGLAND BRANCH.—At Newcastle-upon-Tyne, Thursday, March 20, 2.30 p.m. Prof. E. Farquhar Murray, "Midwifery, Ancient and Modern"; 3.45 p.m., Messrs. H. Harvey Evers, William Hunter, and Stanley Way, Demonstrations. Members of the Services stationed in the area of the Branch are invited to attend.

Meetings of Branches and Divisions

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION

At a meeting of the Swansea Division held at Swansea on January 26, with the president, Mr. HOWELL GABE, in the chair, Dr. W. ERNEST LLOYD gave a lecture on "The Investigation of Diseases of the Chest."

Dr. Lloyd emphasized that an accurate history was essential in diagnosis. Diseases of the chest often suggested themselves by their characteristic history—for example, the sudden onset, usually at night, of bronchial asthma, and the history of a precedent lobar pneumonia, especially in children, followed later by cough and by sputum, which might be purulent, thus suggesting bronchiectasis. Lung abscess, spontaneous pneumothorax, and pulmonary tuberculosis had characteristic features obtainable from the patient's history. Discussing physical examination, he said the impaired percussion note on one side as compared with the other, the diminished air entry on that side, and the position of the apex beat would suggest a pleural effusion. It was important to ascertain the position of the apex beat and to note any change from the normal. Thus the usual methods of examination, beginning first with inspection and palpation, followed by percussion and auscultation, would reveal any obvious differences in either side. Sputum, if obtainable, should be examined. This was especially important in the diagnosis of pulmonary tuberculosis. In cases often considered to be of chronic bronchitis the physical signs of the bronchitis often masked the presence of pulmonary tuberculosis. Radiology should be regarded as part of a complete investigation and should not replace a clinical examination. It was of the greatest value when physical signs were indefinite and the disease was limited to a small area, as in the earliest stage of pulmonary tuberculosis or a localized area of pneumonitis. In cases of pleural effusion a sample of fluid should always be removed for examination.

A vote of thanks to Dr. Lloyd for his address was proposed by Dr. H. R. FREDERICK and seconded by Dr. ESMOND REES.

SUSSEX BRANCH: WEST SUSSEX DIVISION

At a meeting of the West Sussex Division, held on February 6, with Dr. R. H. WILSHAW in the chair, Mr. A. H. MCINDOE read a paper on "Burns," in which he gave reasons for not using tannic acid treatment in certain cases and described his method of treatment. A good discussion followed, many questions being answered by Mr. McIndoe.

UNITED PROVINCES BRANCH

At a clinical meeting of the United Provinces Branch held at Lucknow on August 30, 1940, the chairman, Dr. B. B. BHATIA, showed a case of hypophysial cachexia which had been shown twice before. The patient had improved considerably in many respects and was shown before being discharged. Dr. Bhatia also demonstrated a case of an unusual macrocytic anaemia in a woman of about 35 years responding poorly to liver preparations. An interesting discussion followed.

At a similar meeting held on October 25, 1940, with Dr. BHATIA in the chair, Dr. MOIZUDDIN showed the following cases: (1) paraplegia of the upper motor neuron type of sudden onset; (2) cough and haemoptysis (blood-tinged sputum) without any temperature in a healthy man: x-ray examination of the chest revealed a localized circular shadow on the left side of the chest. The CHAIRMAN demonstrated a case of hysterical paralysis of the lower extremities in a girl of about 10 years. Colonel MOHANI I.M.S., read a paper on "Evolution of Modern Medicine."

B.M.A. LIBRARY

The following volumes were added to the Library during December, 1940, and January, 1941:

Bailey's Textbook of Histology. By Smith, P. E., Carpenter, R. L., *et al.* Tenth edition. 1940.
Bawden, F. C.: Plant Viruses and Virus Diseases. 1939.
Boyden, A. L.: Income Tax for Medical Practitioners. 1940.
Cushny's Pharmacology and Therapeutics. By Edmunds, C. W., and Gunn, J. A. Twelfth edition. 1941.

Medical Services of H.M. Forces

Appointments

ROYAL NAVY

Surgeon Commander W. P. Vicary has been placed on the Retired List.
Surgeon Lieut.-Commander H. A. Clarke to be Surgeon Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Surgeon Lieut. G. Hayes to be Surgeon Lieutenant.
To be Temporary Surgeon Lieutenants: A. Macleod and R. W. Tizzie.
Probationary Temporary Surgeon Lieut. I. F. Logan to be Temporary Surgeon Lieutenant.

ARMY

Major-General F. D. G. Howell, C.B., D.S.O., M.C., late R.A.M.C., has retired on retired pay.
Colonel (temporary Brigadier) J. A. Mansfield, D.S.O., late R.A.M.C., to be Major-General.
Colonels J. S. McCombe, D.S.O., late R.A.M.C., and S. W. Kyle, late R.A.M.C., have retired and remain employed.
Lieut.-Colonels W. K. Morrison, D.S.O., from R.A.M.C., H. C. D. Rankin, O.B.E., from R.A.M.C., and E. Percival, D.S.O., M.C., from R.A.M.C., to be Colonels.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel W. J. E. Bell, D.S.O., retired pay, has reverted to the rank of Major at his own request, whilst employed during the present emergency.
Major D. Crun to be Lieutenant-Colonel.
Major (acting Lieut.-Colonel) P. J. S. O'Grady, has retired and remains employed.
Lieut. W. Allen has resigned his commission.

ROYAL AIR FORCE

Flight Lieut. H. D. Conway has been granted a permanent commission in the substantive rank of Flight Lieutenant.

ROYAL AIR FORCE VOLUNTEER RESERVE

B. Cates, to be Squadron Leader.

Flight Lieut. G. D Dawson has relinquished his commission on account of ill-health.

Flying Officers J. Apley, K. D. F Marle, M. Stein, F. T. Dodd, E. I. B. Hawes, J. A. Partridge, K. A. Boughton-Thomas, E. O. Evans, and J. T. Burrowes have been promoted to the war substantive rank of Flight Lieutenant.

To be Flying Officers for the duration of hostilities: C. C. Edwards, V. E. Gillis, J. T. Murray-Aynsley, J. G. Mathewson, J. C Kitchin, E. H. Hudson, J. Heginbotham, A. Redmond, W. E. C. Taylor, C. W. Hutt, J. A. Ward, W. N. Riley, K. E. Guest, J. M Gray, D. C. Caldwell, R. G. Mayall, D. V. Porter, G. Levy, N. S. Gurrie, D M. Roberts, T. A. Shaw, D. E. Meredith, J. C. Hutchinson, D. O. Hicks, C. W. J. Claydon, L. H. Boyd, A. J. Barwood, J. L. Morgan, K. G. Reynolds, A. Reid, W. E. Rigby, J. S. Hall, K. Hazell, J. Greene, H. H. Glatston, D. R. Sloan, M. Wynne, W. Wynroe, S. D. Perchard.

REGULAR ARMY RESERVE OF OFFICERS

Colonels J P. Lynch, late R.A.M.C., and G. de la Cour, O.B.E., having attained the age limit of liability to recall, have ceased to belong to the Reserve of Officers.

ROYAL ARMY MEDICAL CORPS

Captain (temporary Major) (acting Lieut.-Colonel) E. G. H. Cowen, to be Brevet Major, under the provisions of Article 168, Royal Warrant for Pay and Promotion 1940.

Captains (temporary Majors) D. J. Battetham and G. H. Wood to be Brevet Majors, September 1, 1939, and March 4, 1941, respectively, under the provisions of Article 168, Royal Warrant for Pay and Promotion, 1940.

Captains F. K. Tomlinson, G. Fleming, and H. G. Dresing to be Brevet Majors under the provisions of Article 168, Royal Warrant for Pay and Promotion, 1940.

SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Lieut. (War Substantive Captain) M. Bradford has ceased to belong to the Supplementary Reserve of Officers on account of ill-health.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

War Substantive Major D. G. Coutts has relinquished his commission on account of ill-health and retains his rank.

Captain C. S. France, from Manchester Regiment, to be Captain, October 16, 1940, with seniority August 2, 1935. (Substituted for the notification in the *Supplement* to the *London Gazette* dated November 1, 1940.)

Captain P. J. Gibbons has relinquished his commission on account of ill-health. (Substituted for the notification in the *Supplement* to the *London Gazette* dated April 24, 1940.)

Supernumerary for Service with Aberdeen University Contingent (Medical Unit, Training Corps)—J. S. Young, M.C., late Royal Highlanders, to be Lieutenant.

Second Lieut. H. A. W. Smith, from Unattached List (Infantry), to be Lieutenant.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

P K McCowan to be Lieutenant (without pay and allowances) and has been granted the unpaid acting rank of Lieutenant-Colonel.

The surname of J. MacArthur is as now described and not as stated in the *Supplement* to the *London Gazette* dated January 28.

Lieut. (acting Major) K. B. Dickson, T.D., to be Lieutenant, and has relinquished the rank of Major. (Substituted for the notification in the *Supplement* to the *London Gazette* dated March 19, 1940.)

Lieuts. (War Substantive Captains) S. F. Ferguson and A. de Redder have relinquished their commissions on account of ill-health.

The surnames of Lieuts. W. J. McGinness, F. B. Yonge, and Y. Ivenitzki are as now described, and not as notified in the *Supplements* to the *London Gazette* dated March 5, 1940, and January 10 and 14, 1941, respectively

Lieuts. V. W. Maxwell and A. G Martin have relinquished their commissions on account of ill-health.

Lieut. J H. Hill has resigned his commission.

To be Lieutenants: H. R. Chapman, H. S. Marwick, D. E. Dunnill, J. G Hughes, J. N. Strauss, R. D. Firth, D. N Kelsey, P. Franklin, B. P. Armstrong, A. M. Boyd, I. B. Cadas, A W. Chester, E. L. Cohen, D. V. Davies, J. H. Lancaster, T. E Jones-Davies, R. McNeilly, H. Matthews, J. Minton, H. B. Morris, S. H. Segerman, R. Shaw, D. W. Shields, R. West, J. Alcorn, G. W. Aston, E. McL. Barbour, E. M. Calvey, B. S. Carter, D. H. Cammack, J. T. Farr, H. J. Friend, C. E. Gorrod, J. W. Gibson, T. W. Greatorex, T. S. Heslop, R. S. Hynd, J. Irvine, W. M. Jones, J. D. McGregor, A. Rapoport, G B. Robinson, S. Smith, W. Somerville, H. E. Stewart, D W. Warren, R. T. B. Watson, G. A. Wilson, H. Burton, R. Carmichael, H. Doyle B Day, D. P. Clahane, J. A. Crawford, S. S. Davidson, D. Ferguson, A. Tober, A. Y. Adam, J. O. Collin, W. I. Daggett, C. G MacB. Donaldson, J. Essex, J M. Fleming, L. C. L. Gonet, A. D. Gould, G C. Gundersen, J Hynes, C. K. B. Lennox, E. R. R. Mellon, M C Muir M E Moore, E. A Ritchie, A. I. Shaw, R. H. Smythe, A. A. Spiro, D C Sturdy, W. G. Sugden, I. M. Vites, B. J. Wilton, W. T. J. Fowler C V. A Henriques, J. Lubran, F. H. Scoones, J. D. To be Medical Officers with the relative rank of Lieutenant: Christine F. Saville, Muriel H. E. Long, Jean M. Laidlaw, Edith K. P. Harris, Dorothea Graham-Service, Alice P. M. Hennessy, Albertine L. Winner, Bridget S. Gurney, Joan Halstead, Adelaide E. Anderson, Muriel B. O'Dogherty, Mabel Bain, Clare F. Lyons.

ARMY DENTAL CORPS

I. W. E. Snawdon, M.B., to be Lieutenant.

Postgraduate News

The Fellowship of Medicine announces the following postgraduate courses for Final F.R.C.S. candidates: (1) orthopaedics (theoretical lecture-demonstrations, illustrated by *x*-rays, on Wednesdays 2.30 p.m., at Medical Society of London, 11, Chandos Street, W March 26 to April 30; (2) comprehensive revision course at Roy Cancer Hospital, clinical and theoretical teaching, daily, 10 a.m. 1 p.m., March 31 to April 25; (3) practical operative surgery cours thrice weekly, 2 p.m., March 31 to April 25.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpol Street, W.—*Brompton Hospital*, S.W.—Mon. and Thurs., 4.45 p.m. M.R.C.P Course in Chest Diseases. *West End Hospital for Nervous Diseases*— Tues. and Fri., 3.30 p.m. Clinical Demonstrations in Neurology. *Roya National Orthopaedic Hospital*, Stanmore.—Sat., 2.15 p.m. F.R.C.S. Clinica Orthopaedic Course. *Medical Society of London*, 11, Chandos Street, W.— Tues., 2.30 p.m. F.R.C.S. Neurological Surgery Course: (1) and (2) Sym pathetic Nervous System.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Pathology.—Tues., 3.45 p.m. Annual General Meeting. Papers by Dr. D. M. Pryce, A Simple Method of Growing Tubercle Bacilli in Sputum Films; Dr. R. A. Kekwick and Dr. B. R. Record, The Electrophoretic Fractionation of Diphtheria Antitoxic Horse Serum; Dr. Douglas McClean, The Capsulation of Streptococci and its Relation to Hyaluronidase (Diffuse Factor); Mr. A. D. McEwen, Problems Relating to the Immunization of Cattle against *Br. abortus*.

Section of Neurology.—Wed., 2 p.m. Exhibition of Pathological Specimens and Preparations. 2.30 p.m., Discussion, Fat Embolism of the Brain. *Openers*, Drs. A. H. Robb-Smith, Dorothy Russell, J. G. Greenfield, and A. H. Hunt.

Section of Dermatology.—Thurs., 4 p.m. Short illustrated papers on "Clinical Photography" by Drs. J. H. Twiston Davies, F. A. E. Silcock, F. S. Airey, and Mr. T. Pomfret Kilner. Histological sections will also be shown.

Clinical Section.—Fri., 2.15 p.m. Meeting at King's College Hospital, Denmark Hill, S.E.5. Cases and specimens.

Section of Radiology.—The meeting announced to be held on Friday, March 21, has been postponed. Further details will be announced later.

BIOCHEMICAL SOCIETY.—At University College Hospital Medical School, University Street, W.C., *Fri.*, 2 p.m. Meeting.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant apointments are announced: Sherborne (Dorset); Markinch (Fifeshire). Applications to the Chief Inspector of Factories, Cleveland House, Page Street, S.W.1, by March 25.

APPOINTMENTS

DICK, Nancy K., M.B., B.S., M.R.C.S., L.R.C.P., Deputy Medical Superintendent, South Middlesex Emergency and Fever Hospital.

BIDEN-STEELL, K., M.D., has been appointed one of His Majesty's Inspectors of Factories.

EXAMINING FACTORY SURGEONS.—G. T. Drummond, M.B., Ch.B., for the Coatbridge District (Lanarkshire); G. I. Lambe, M.B., B.Ch., B.A.O., D.P.H., for the Darlaston District (Staffordshire); G. S. Landon, M.R.C.S., L.R.C.P., for the Lewisham District (London).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. The amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

BIRTH

REID.—On February 27, to Rosamund (*née* Hench) and Dr. T. H. Reid, of Woodnook, Selston, Notts, a son.

CRUSH INJURIES WITH IMPAIRMENT OF RENAL FUNCTION

BY

E. G. L. BYWATERS, M.B., B.S., M.R.C.P.

Beit Memorial Fellow

AND

D. BEALL, Ph.D.Toronto

(From the Departments of Medicine and Pathology, British Postgraduate Medical School)

[WITH SPECIAL PLATE]

Amongst air-raid casualties seen at this hospital have been four cases of crush injury of the limbs which, because of the general similarity of their clinical course, were thought to represent a specific and hitherto unreported syndrome, and one which has been and will be seen elsewhere during the war. Such a condition may have been observed in civil practice, but we have been unable to find any account of it in the literature. The cases are of interest on account of the problem propounded by both pathogenesis and treatment. The picture presented by these four cases, and substantiated by others, is briefly as follows:

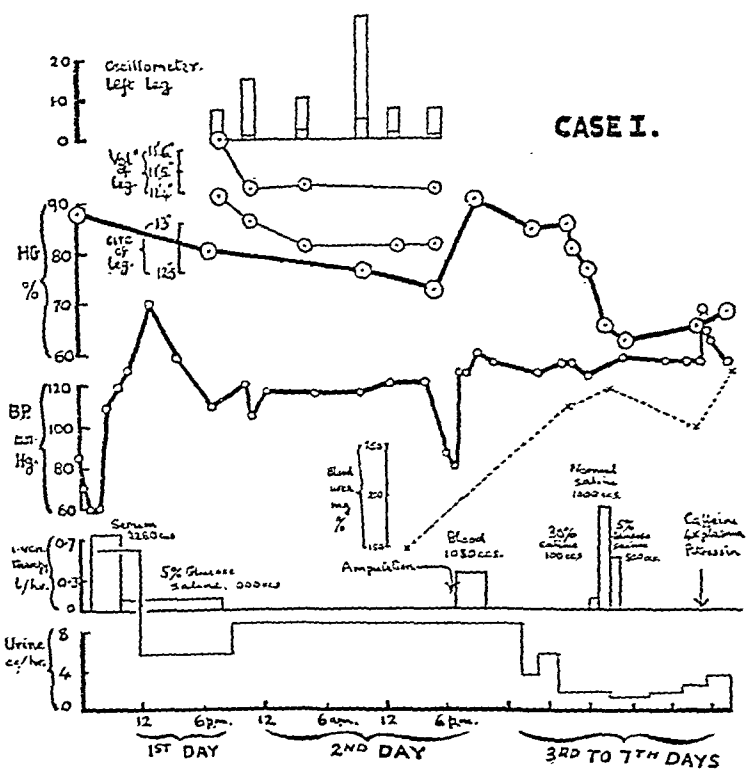

CHART I.—Case I.

The patient has been buried for several hours with pressure on a limb. On admission he looks in good condition except for swelling of the limb, some local anaesthesia, and wheals. The haemoglobin, however, is raised, and a few hours later, despite vasoconstriction, made manifest by pallor, coldness, and sweating, the blood pressure falls. This is restored to pre-shock level by (often multiple) transfusions of serum, plasma, or, occasionally, blood. Anxiety may now arise concerning the circulation in the injured limb, which may show diminution of arterial pulsation distally, accompanied by all the changes of incipient gangrene. Signs of renal damage soon appear, and progress even though the crushed limb be amputated. The urinary output, initially small, owing perhaps to the severity of the shock, diminishes further. The urine contains albumin and many dark brown or black granular casts. These later decrease in number. The patient is alternately drowsy and anxiously aware of the severity of his illness. Slight generalized oedema, thirst, and incessant vomiting develop, and the blood pressure often remains slightly raised. The blood urea and potassium, raised at an early stage, become progressively higher, and death occurs comparatively suddenly, frequently within a week. Necropsy reveals necrosis of muscle and, in the renal tubules, degenerative changes and casts containing brown pigment.

Case I

A female aged 17 had been buried for nine hours with heavy masonry lying across the left leg. On admission she showed slight bruises generally, and multiple superficial abrasions below the left knee. The leg was swollen and sensation was impaired at the ankle, where all power and movement were lost. Other limbs appeared undamaged. The skin was pallid and clammy; the blood pressure was 85/70 mm. Hg. The clinical course is shown on Chart I. Recalcified plasma-saline (Clegg and Dible, 1940) (subsequently referred to as "serum"), followed by 5% glucose-saline,

brought the blood pressure from 60 mm. Hg, where it had remained for one and a half hours, to 160 mm. Hg. Urine was passed containing neither albumin nor blood.

By 7 p.m. the haemoglobin concentration had fallen. Blisters were forming on the left knee, where there was a joint effusion. Less oedema of the leg was now present than on admission; measurements were made of leg circumference, of leg volume (by a tape method),* and of pulsation by means of an oscillometer. During the next twenty-four hours the volume and circumference of the leg decreased. However, the oscillometer readings, after a deceptive rise towards normal, fell to the low initial level, even though during this

period the left leg had been bandaged and elevated to 50 degrees on a Thomas splint for two hours. The second specimen of urine still showed neither albumin nor blood.

By 6 p.m. the next day the left leg was cold below the knee and blue, and amputation was proposed. This was done under vinesthene and gas-and-oxygen. Citrated stored blood (Group O) was given during and after operation, restoring the blood pressure, which had temporarily fallen, to the pre-operative level. Urines collected after this showed albumin and gave a positive benzidine reaction; hyaline, granular, and what appeared to be red cell casts were noticed, besides free red corpuscles.

During the next five days the patient continued drowsy and apathetic, from which state she was easily roused by the slightest stimulus to become anxious and apprehensive, without, however, any loss of mental clarity. The output of urine became very small, despite a fluid intake by mouth of between 1.5 and 2.5 litres daily; vomiting continued (between 50 and 250 c.cm. daily). Normal saline (1 litre), 30% saline (100 c.cm.), and 5% glucose-saline, followed later by caffeine benzoate (140 mg.), 85 c.cm. of four-times-normal reconstituted dried serum (obtained from the Medical Research Council serum-drying unit), with, in addition, pitressin 1/100,000, were given intravenously, and hot bottles were applied to the loins. Despite these measures, directed towards restarting urine flow, the patient, whose blood pressure was maintained at 130/70, suddenly collapsed at 12.13 p.m. on the eighth day and died in three minutes. A systolic murmur at the apex and dropped beats had been noticed for forty-eight hours before death, and an electrocardiogram taken forty-one hours before death showed merely low voltage. A second, sixteen hours later, showed widening of QRS, higher voltage, increase in Q_1, and inversion of T_3. Biochemical findings are listed in Tables I and II. Necropsy was performed two and a half hours after death.

SUMMARY OF POST-MORTEM RECORD BY DR. THOMAS BELT

The point of major interest was the condition of the kidneys. They were large, weighing 210 and 230 grammes respectively, rather dark red and firm, quite smooth of surface, having tense capsules due to swelling of the cortices. The cut edges everted; the cut surfaces were wet and glassy owing to oozing of serous fluid. Parts of cortex midway between renal pyramids were blanched by a zonal ischaemia. There was no evidence of ascending infection. The bladder was slightly reddened, and contained a few drops of very thick cloudy urine. Subcutaneous and retroperitoneal tissues oozed serous fluid when cut, indicating a slight generalized oedema. Marked cyanosis was evident in the internal parts, but the skin was pale. Other organs and tissues presented no striking change.

Microscopical Examination.—Kidney: The main change was to be found in the tubules. The convoluted tubules and the loops of Henle were severely damaged. The cytoplasm of the lining epithelium was swollen, frayed, granular, and vacuolated. Individual cells here and there were devitalized and desquamated, while those that remained attached showed fairly frequent mitotic figures. The cast-off cells in various stages of disintegration merged in the lumina with loose collections of eosinophilic debris. In the loops of Henle and the collecting tubules there were numerous casts of dense eosinophilic material, most of which had a brownish colour, as though lightly stained with bile or blood pigment. These casts seemed to be all of the same substance, though their morphological appearance varied a good deal, depending upon the degree of condensation they had undergone. Some looked not unlike collections of disintegrating erythrocytes; others simulated shreds of fibrin or beaded ribbon, while still others were condensed into solid hyaline cylinders. They seemed to be compounded of dead epithelial cells, inspissated albumin, and perhaps hyaline material exuding from the lining of the tubules. One could identify an occasional erythrocyte within the tubules, but, so far as could be determined by histological means, the majority of the casts were not red cell casts, though some of their colour might have been due to haemoglobin. They were probably not of a specific type, as similar casts are to be seen in acute nephritis and other conditions where there seems to have been great reabsorption in the tubules, resulting in a scanty concentrated urine. Some of them were surrounded and invaded by leucocytes, and, in the lower reaches of the straight tubules, leucocytes were sometimes the predominant constituent. Here and there a cast-filled tubule was undergoing disintegration and was surrounded by inflammatory cells. Stains for iron were negative. Fatty changes were absent. The glomeruli showed no obvious structural change, though the frequent presence of albuminous material in Bowman's capsule suggests that they had not escaped injury. The glomerular tufts contained relatively little blood, but the vessels of the medullary parts were greatly engorged.

Other Tissues.—Thyroid: Signs of commencing activity with increased height of cells and many mitoses. *Liver:* cloudy

* Worked out in conjunction with D. K. Hill. An inextensible tape of width (w) is wound round the limb without overlapping. The length of tape (L), thus enclosing a certain volume (V) by a number of turns (n), is given by the formula:

$$L = \sqrt{\frac{4\pi nV}{kw}}$$

where k is a constant dependent on the shape of the leg. In Case I direct measurement of volume by water displacement gave k a value of 0.90.

swelling but no necrosis. Adrenal: patchy loss of cortical lipoid. Heart: vacuolation of neuromuscular fibres (bundle of His). Muscles of right leg: not abnormal.

The amputated leg showed haemorrhage in the popliteal fossa around the artery, extending along the intermuscular fascial planes. There was no oedema beneath the deep fascia, but slight superficial oedema with punctate haemorrhage was present over the pressure areas in the skin. There was a haemarthrosis of the knee-joint, with cracks in the patella and tibial cartilages, extending down across the bone of the tibial condyle. Sections of artery showed no lesion: sections of muscle (which macroscopically looked normal) revealed a few fibres (1%) undergoing necrosis, with loss of striation and staining power.

Case II

A female aged 45 had been crushed under a collapsed building for six hours. On admission there was a large scalp wound and lacerations and bruises of both legs, on which debris had been pressing. Both calves were extremely hard, swollen, and tense. The blood pressure was 130 98, and, despite considerable bleeding from the scalp, the haemoglobin amounted to 92%; the pulse was 130. (See Chart II.) Measurements were taken of leg volume. Pulsation (oscillometer) was decreased in both legs. The scalp wound was sutured under gas-and-oxygen and ether.

Two hours later haemoconcentration developed and the blood pressure fell. Repeated infusions of "serum," plasma, and saline restored the blood pressure to 115 mm. Hg; then, following a transfusion of citrated stored blood, to the abnormally high level of 160 mm. Hg. With the rise in blood pressure the volumes of both legs increased, and the oscillometric readings fell. Dark smoky urine was obtained by catheter next day, showing albumin and red cell and hyaline casts.

At 2 p.m. she was vomiting and had oedema of the face, eyelids, and arms as well as the legs. Venous blood showed raised urea (115 mg.), plasma chloride (801 mg. as NaCl), and serum potassium (28 mg.), and a lowered CO_2-combining power (41 c.cm. per 100 c.cm.). Pulsation had returned in the right leg but not yet in the left. The chloride content of the body was therefore reduced (by sweating, purgation, and replacement of gastric juice by sodium bicarbonate) and the oedema disappeared, except from the legs. During the next three days her condition remained the same: the blood pressure reached as high as 168 104, and, while the plasma chloride and alkali reserve fell, urea, phosphates, and potassium steadily rose. Urinary output was very low (50 c.cm. daily) in spite of a daily intake of between 1½ and 2 litres. The urine became blood-free but infected (catheterization), and showed a low chloride concentration.

On the sixth day at 11.15 p.m. the patient became distressed, cold, and wet with sweat: a systolic murmur was heard at the apex and the blood pressure fell to 106 85. An electrocardiogram taken before this (at 7 p.m.) showed bundle-branch block. The pulse suddenly fell to 70 (previously steady at 100) and showed dropped beats. She died at 12.10 a.m. on the seventh day. Biochemical findings are shown in Tables III and IV.

SUMMARY OF POST-MORTEM RECORD BY DR. THOMAS BELT

Necropsy twelve hours after death: Calf muscles on both sides showed widespread necrosis. They were blanched and swollen as if parboiled, and mottled with haemorrhagic areas. The vessels of the legs were apparently undamaged. The kidneys were relatively large (weighing 190 and 170 grammes), smooth, tense, and dark red. There was no pyelitis. The bladder mucosa was slightly reddened; the liver was swollen (1,830 grammes); and the lungs were slightly oedematous (500 grammes each).

Microscopical Examination.—Kidney changes were very much like those in Case I. There were perhaps more leucocytes in the tubules, and these occasionally extended right up into the cortex. The liver showed cloudy swelling but no necrosis. Muscle displayed widespread necrosis, chiefly coagulative but becoming liquefactive in small foci. There was much patchy haemorrhage and polymorph reaction in disintegrating areas, but no bacteria. Some small vessels in the section showed necrosis of the wall. The pancreas had a few patches of fat necrosis, and the adrenal gland showed patchy loss of cortical lipoid. Other tissues appeared normal.

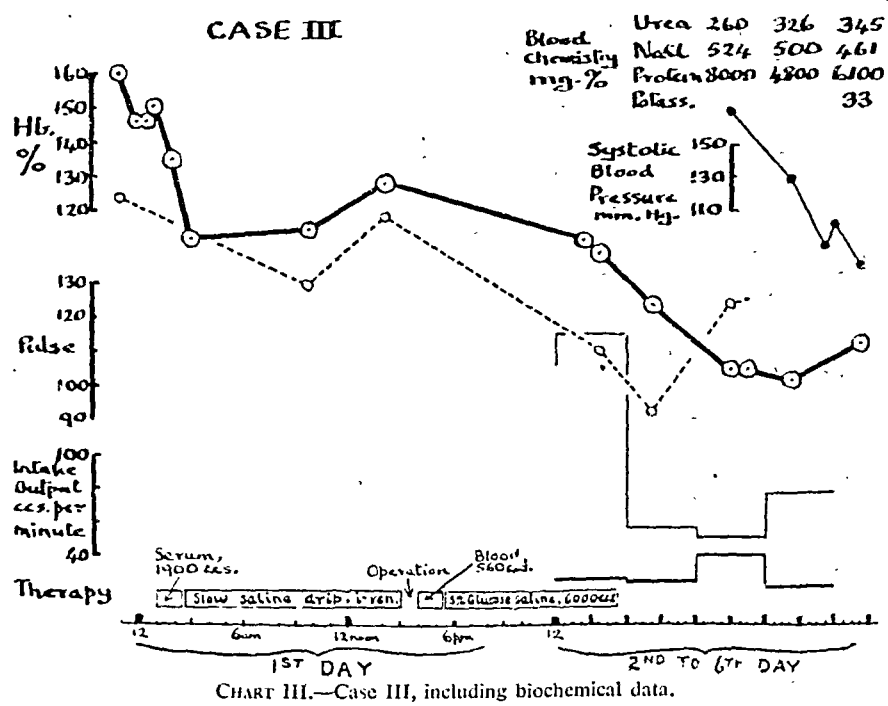

CHART III.—Case III, including biochemical data.

Case III

A male aged 34 was pinned down by beams across shoulders, arms, and thighs for twelve hours. On admission he was pale and shocked, with great swelling of both arms and thighs, and skin-whealing at pressure sites. There was occasional vomiting (about 120 c.cm. daily). The blood pressure could not be taken on account of the swelling. 1,900 c.cm. of "serum" was given intravenously over ninety minutes, reducing the haemoglobin from 160 to 112%. (See Chart III.) Next day the left arm appeared greatly swollen, and the hand blue, cold, and pulseless. An incision was therefore made from mid-arm to below the elbow, relieving the tension beneath the deep fascia so that the brachial artery again began to pulsate. This was followed by a transfusion of 460 c.cm. of blood (Group O). Urine was passed—specific gravity 1015—containing albumin and blood but no casts. On the third day the left hand was warm but still devoid of sensation and power: there was oedema of both thighs, but a radiograph showed that there was no bony lesion. The patient continued to vomit about 100 c.cm. daily; 6 litres of 5% glucose-saline had been given intravenously over this and the previous day. There was some incontinence of urine, of which, however, 655 c.cm. was collected. On the fourth day, despite a fluid intake of 1,340 c.cm., 590 c.cm. of urine was passed, still containing albumin. At 5 p.m. the temperature rose suddenly to 103.4°, and there was some redness around the site of the intravenous puncture. Sulphapyridine by mouth was started. On the fifth day vomiting, dyspnoea, and slight generalized oedema occurred, with crepitations at both bases and a pleuro-pericardial friction rub. A radiograph revealed slight basal congestion only; an electrocardiogram showed right axis deviation; the blood pressure was abnormally high (170–180 mm. Hg), and, despite a urinary output of 990 c.cm. in the day (on an intake of 1,230 c.cm.), the blood urea was 260 mg., the total plasma protein 8.0 grammes, and the plasma chlorides (as NaCl) 500 mg. per 100 c.cm.

During the sixth day the blood pressure fell progressively without further concentration. At 8 p.m. the patient had become delirious and disorientated, and the pulse rapid. The skin became cold, wet, and cyanosed. Coarse crepitations were heard at both bases: there was incontinence of urine, of which 530 c.cm. was collected, showing albumin and numerous red cells but no casts in the deposit. Oxygen was given. The fluid intake was 1,860 c.cm. The blood urea was 326 mg., the total plasma proteins 4.8 grammes, and the plasma chlorides (as NaCl) 500 mg. per 100 c.cm.

Death occurred on the seventh day, 160 minutes before death the blood urea was 345 mg., the total plasma proteins 6.1 grammes, the plasma chlorides (as NaCl) 461 mg., and the serum potassium 33 mg. per 100 c.cm.

SUMMARY OF POST-MORTEM RECORD BY DR. THOMAS BELT

Necropsy showed staphylococcal pyaemia due to thrombophlebitis of saphenous veins. There was extensive crushing of leg muscles. Microscopically, tubular changes in the kidneys resembled those of Cases I and II. There were numerous casts of similar character, but the picture was somewhat complicated by the presence of a few small pyaemic abscesses.

Case IV

A male aged 16 was buried under a collapsed house for eight hours, the left thigh being pinned down by a heavy load of masonry. On admission the systolic blood pressure was 140 mm. Hg, and superficial abrasions were present on the left thigh, later becoming whealed. On getting out of bed that afternoon he fainted. At 8 p.m. he suddenly collapsed; the haemoglobin had risen to 140% and the blood

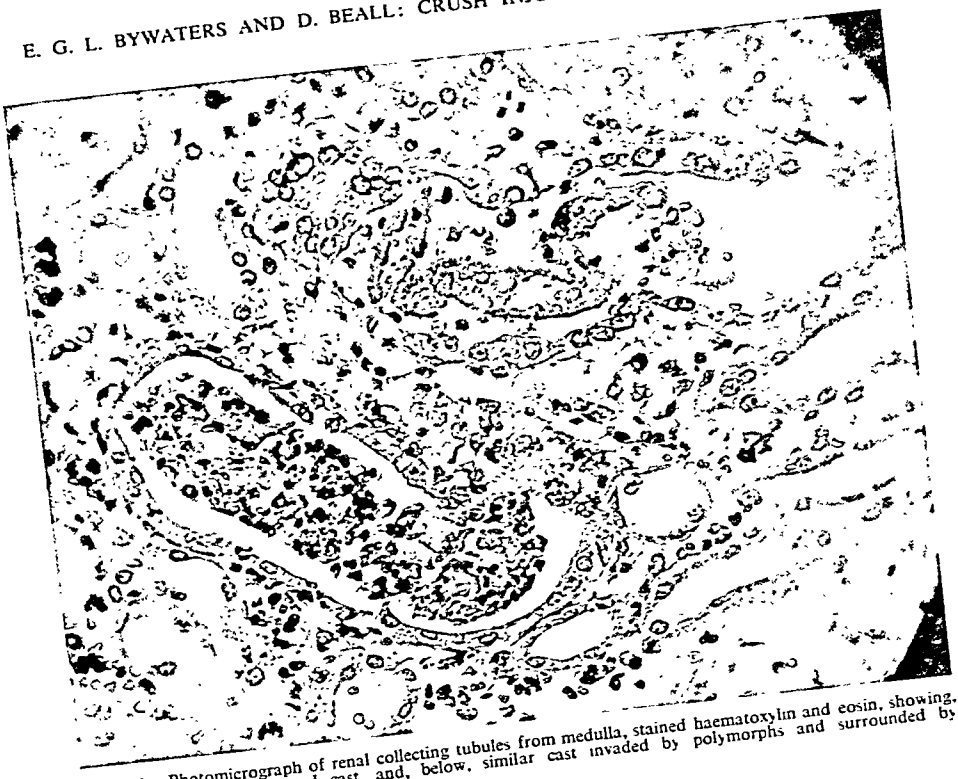

FIG. 1.—Photomicrograph of renal collecting tubules from medulla, stained haematoxylin and eosin, showing, above, ribbon-like pigmented cast, and, below, similar cast invaded by polymorphs and surrounded by desquamated epithelial cells. × 300

FIG. 2.—Photomicrograph of renal tubule from boundary zone, stained haematoxylin and eosin, showing necrosis of wall and commencing reactive changes. × 280.

pressure had fallen to 40 mm. Hg; the pulse rate was 108 per minute. Venous blood showed plasma protein to be 9.1 grammes and chlorides (as NaCl) 545 mg. per 100 c.cm. He was given normal saline, and then "serum" intravenously, which, as may be seen from Chart IV, brought the blood pressure to 96 mm. Hg, and the haemoglobin down to 85%; plasma protein was 7.9 grammes and chlorides (as NaCl) 705 mg. per 100 c.cm. This was immediately followed by serum, which effectively lowered the haemoglobin and

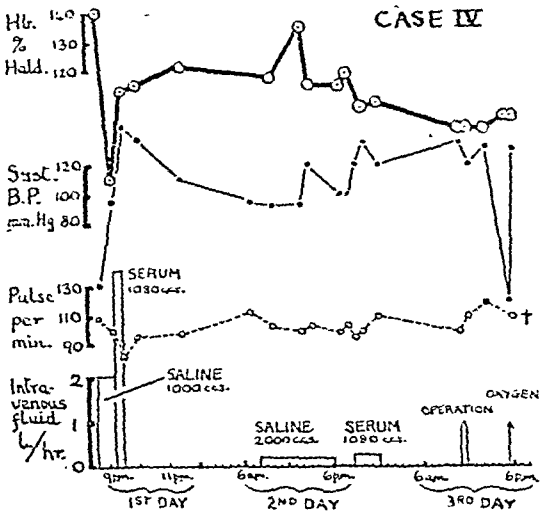

CHART IV.—Case IV (admitted nine hours before the beginning of this chart with a blood pressure of 140 mm. Hg).

raised the blood pressure to a comparatively high level. Next day further serum was given. On the third day the condition of the left foot, which had caused considerable anxiety, was worse: extensive oedema of the thigh had apparently cut off the circulation to the left foot, which was cold and pulseless. Under gas-and-oxygen and ether anaesthesia, incision was made into the left thigh to relieve pressure on the vessels: a feeble pulse was temporarily restored in the posterior tibial artery. Tissue fluid from the thigh contained 1.9 grammes of protein per 100 c.cm. Five hours after the operation the patient suddenly collapsed; although the haemoglobin remained at 105%, the blood pressure fell to 30 mm. Hg. After giving oxygen by B.L.B. mask the pressure rose to 130/82. This restoration of blood pressure was, however, only temporary, and the patient died three hours afterwards. During the last two days there was much vomiting and the abdomen was extremely tense. The urinary output was very low throughout.

Necropsy, by Dr. Keith Simpson, forty-eight hours after death, showed crushed and oedematous muscles of the thigh, with interstitial haemorrhages. There was no bony lesion, no injection, and no gross change in other organs.

On microscopical examination (Dr. Thomas Belt) the muscle showed patchy necrosis, and infiltration with polymorphs. The kidney and other organs were not thus examined.

Discussion

THE RENAL LESION

This consists structurally of severe degenerative changes in the proximal convoluted tubules and, in the more distal part of the nephron, brown pigmented casts of a colour, in unstained preparations, similar to that of blood corpuscles. There are reactive changes round the casts and desquamated epithelium in the medulla (Figs. 1 and 2 on Plate). The matrix of the casts is thought, on histological grounds, to be composed not of red corpuscles but of desquamated epithelial cells. The pigment might therefore be accounted for either by excretion into the lumen from the blood stream of haemoglobin, myohaemoglobin, or bile pigment, or possibly by the extrusion into the lumen of cells already pigmented.

Changes very similar to these are described following mismatched transfusion (Witts, 1929; Goldring and Graef, 1936; Baker, 1937). There is the same absence of changes in glomeruli, and similar changes in the convoluted tubules, in the interstitial tissue, and in the straight tubules. The casts are not composed of red cells, but sometimes there are spherical bodies resembling them. Baird and Dunn (1933) and others have noted similar casts containing "haemoglobin" in eclampsia.

The effect on function of blockage by casts is obscure: if this were the only lesion, what urine was secreted (through unobstructed tubules) should be of normal composition. The urine resembled, however, more a glomerular filtrate; there was no significant concentration of urea (hence no selective absorption of water), and in Case I there was failure to reabsorb chloride when the blood level was below 500 mg. per 100 c.cm. Case II showed some degree of chloride reabsorption. There thus appears to be dysfunction of the convoluted tubules. Whether partial blockage or blockage of a few tubules—cf. the kidney after mismatched transfusion, in multiple myeloma (Forbus *et al.*, 1935; Holman, 1939), and in calcification affecting the pyramids (Albright *et al.*, 1940)—can so raise the intrarenal pressure as to interfere with tubular function as well as with glomerular filtration is not known. It has recently been suggested (Navasquez, 1940) that the degree of tubular blockage is not sufficient to account for the symptoms associated with "transfusion kidney." The hypertension in Cases II and III, and also noted in the case reported elsewhere in this issue (Mayon-White and Solandt, p. 433), may be allied to other types of primary "renal hypertension."

It is possible that minor degrees of this renal damage may occur, since at least one patient with crushed limbs has been observed to recover completely (R. V. Christie, personal communication) with a raised blood urea and low urea clearance. In a similar case of muscle crush seen elsewhere (Beall, Belsey, Bywaters, and Miles, unpublished data) there was a definite tendency towards recovery of renal function, shown by the increasing resorption of both water and chloride. Certain cases of post-operative anuria may prove to fall into this category, but the majority of them appear to be associated mainly with decreased blood volume and blood pressure, since restoration of blood volume to normal improves the renal output.

In Case I fibroblast increase and tubular dilatation were much more prominent than in the other cases. The latter may in part be related to the strong therapeutic stimulation, as caffeine raises the glomerular capillary pressure, with a resultant increase in filtrate (Verney and Winton, 1930).

Aetiology of the Syndrome

Muscle necrosis is the one aetiological factor common to these cases and to those observed elsewhere. It was of limited extent in Case I, although comparison with the degree of necrosis in the other cases is difficult, since the leg was removed thirty-six hours after admission. It would seem of some significance that, in spite of amputation in this case, the time interval between injury and death was of the same order as in the others.

It is known that when muscle is injured its permeability increases and intracellular ions such as potassium leave it rapidly (Horton, 1930). This may be related to the early

increase noted in serum potassium. An evaluation of the relative importance of muscle injury, renal insufficiency, and possibly adrenal cortical deficiency in the composition of this biochemical picture must await the accumulation of further data.

Oliguria in shocked patients may be due to dehydration, sweating, and the fall in blood pressure (since a pressure below 75 mm. Hg is insufficient to produce urine in the absence of circulating diuretic substances—Winton, 1937). The fall in blood pressure lasted for one and one and a half hours only in Cases I and II. Such oliguria certainly facilitates the precipitation of relatively insoluble material in the tubules both in man (e.g., sulphapyridine calculi) and experimentally (e.g., haemoglobin, Yorke and Nauss, 1911). Another possible cause for anuria in air-raid casualties receiving sulphapyridine is the formation of calculi at the uretero-vesical junction (Sadusk *et al.*, 1940). None of these seemed to be of primary significance in the cases cited.

The part played by transfusion fluids (three of these patients received Group O blood as well as plasma and "serum") must be considered, inasmuch as the pathological changes resemble closely those of the "transfusion kidney." There was no evidence clinically of a transfusion reaction, although such can occur in the absence of one or, rarely, all of such symptoms as rigor, chill, backache, and jaundice. Plasma samples taken at seventeen and a half and forty hours after transfusion showed no increased colour. Further, although in Case I, before blood transfusion, haematuria and albuminuria were absent, the high blood urea and low urinary output suggested impairment of renal function. The case reported by Mayon-White and Solandt in this issue (p. 433), and six other cases of which we have heard, received no blood, but plasma or reconstituted serum only. Perhaps, however, the most potent argument against these being due merely to transfusion reactions is that no such condition has occurred in any of 25 shocked and injured patients without severe muscle crush treated in this hospital by blood or "serum" transfusion.

Treatment

The treatment of this condition so far has been by trial and error. It has been directed primarily to restoring urinary output by means of heat to the loins, by saline dilution of plasma protein (thus increasing the glomerular filtering force), by increasing blood volume with serum and hence blood pressure (thus increasing the glomerular capillary pressure), and by the use of diuretics such as caffeine. Decapsulation should perhaps be tried, as it has been shown to reduce the intrarenal pressure (Winton, 1937). In transfusion kidney this has been done twice with successful results (Bancroft, 1925; Younge, 1936).

The effect of adrenal cortical extract in this condition should also be observed, in view of the raised potassium. The development of electrocardiographic changes in Case I was not associated, however, with any significant alteration in serum potassium (cf. Thomson, 1939). In Case II the changes were similar to those seen in many patients a few minutes before death (Wood, personal communication). However, it is unknown whether changes in the heart muscle manifest electrocardiographically were concerned in the striking terminal collapse.

Prevention by early amputation was thought adequate in Case I; it is evident that thirty-six hours was not early enough. Whether there exists an alternative to immediate amputation we shall learn only by further and fuller investigation of such patients and by careful observation of the effects of treatment, or if the condition can be reproduced in the laboratory. Investigations which are designed to induce such a condition experimentally are already in progress at this institution.

Summary

Four cases of crush injury to limbs, producing shock, are described in which after recovery due to replacement of circulatory fluid the patients showed oliguria and pigment casts. They died in about one week with nitrogen retention. Necropsy revealed degenerative changes in the proximal convoluted tubules and pigment casts in the more distal part of the nephron. The aetiology and possible lines of treatment are discussed.

We are grateful to our colleagues engaged on shock research at the British Postgraduate Medical School for their co-operation and participation in this study—in particular to Prof. Dible and Dr. Thomas Belt, and to Dr. J. Clegg, who supplied the serum. Our thanks are also due to the Chief Medical Officer of the London County Council for permission to publish this report.

A CASE OF CRUSH INJURY WITH RENAL FAILURE

BY

D. BEALL, Ph.D.

AND

E. G. L. BYWATERS, M.B., M.R.C.P.

British Postgraduate Medical School

R. H. R. BELSEY, F.R.C.S.

AND

J. A. R. MILES, M.A., M.B., B.Ch.

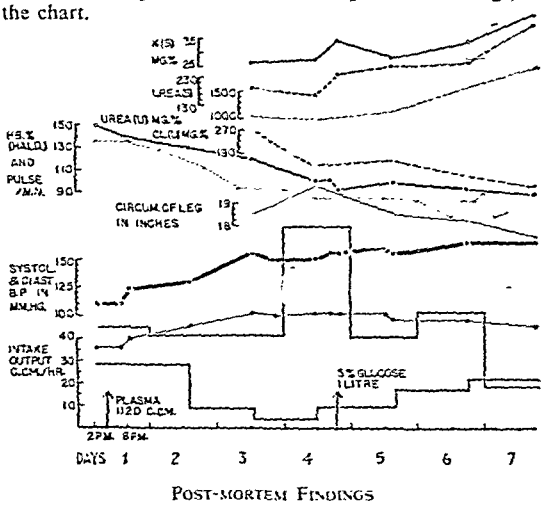
St. Thomas's Hospital

When a bomb demolished a hostel at 4 a.m. in January a young male leather-worker of 20, of medium height and good physique, was buried beneath the debris and his left leg was crushed against the side of an iron bedstead by a heavy metal girder. Morphine grain 1/4 and hot drinks had been administered and hot bottles applied to the trunk while attempts were made to extricate the man. When he was first seen at 1.30 p.m. the left leg was still trapped, his mental condition was apathetic, the extremities were cold, and no pulse was palpable at the wrists. He was finally released at 2.15 p.m., ten hours and fifteen minutes after the accident.

On admission to St. Thomas's Hospital the blood pressure was 110 mm. Hg systolic and 70 mm. diastolic, and the pulse rate 136 per minute. The haemoglobin concentration, determined by the Haldane method, was 150% (ear). He was pale and lethargic but not cyanosed, and complained of no pain. The left leg was swollen and

tense from six inches below to four inches above the knee-joint. There was no external wound of the limb, the pulsation of the dorsalis pedis and posterior tibial arteries was easily palpable at the ankle, and complete physiological interruption of the peroneal nerve appeared to be present. Physical examination revealed no further injuries. The temperature (mouth) was 97° F. on admission and rose rapidly to 99.6°.

During the first two hours after admission he vomited and his pulse rate tended to rise, while the haemoglobin concentration remained constant. He was therefore given 1,120 c.cm. of stored plasma in a hundred minutes. From this time onward the blood pressure began to rise, reaching 130 systolic and 88 diastolic twenty-four hours after admission, and 155 systolic and 100 diastolic on the third day. In spite of an adequate fluid intake the output of urine dropped from 650 c.cm. on the second day to 205 c.cm., by catheterization, on the third. At this time the patient was drowsy and occasionally vomiting small quantities. A loud systolic murmur was present at the apex, which was three and a half inches out in the fifth space. The left leg was swollen and tense from tip to ankle and showed pitting oedema. The pulse in both the dorsalis pedis and posterior tibial arteries was stronger on the injured than the uninjured side. A catheter specimen of urine was brown in colour, with a large dark brown sediment consisting chiefly of blood-pigment casts. *X*-ray examination disclosed a fracture of the tibia in the middle of the shaft without displacement. Venous blood at this time contained increased urea, potassium, and phosphate (see Table), and an electrocardiogram revealed slurring of the RST segment.



On the fourth day ineffectual vomiting continued. There was now no murmur at the apex. Swelling of the left leg above the knee had increased. The urine was a clear yellow fluid, and microscopically a rare blood-pigment cast was found. The benzidine test was negative. One litre of 5% glucose was given intravenously. After this, on the fifth day, the urinary output was 250 c.cm.; there was no sediment and the benzidine test was negative. The patient was still vomiting, drowsy, and slightly disorientated, but neither anxious nor apprehensive. The left leg had decreased in size. On the sixth day the patient seemed more alert and in good condition. The output of urine increased to 490 c.cm. and only an occasional pigment cast was present. There was less oedema of the thigh, but some pitting oedema had appeared in the right foot. The systolic pressure had risen to 165 mm. Hg and the diastolic had fallen to 95. After the first twenty-four hours the temperature had remained normal.

On the morning of the seventh day the patient complained of lack of fresh air. At 4 p.m., despite slight mental depression, he seemed quite well. At 6.15 p.m. he was still slightly disorientated, but both apprehensive and anxious. The nostrils dilated with inspiration, there were some cyanosis and marked stertor, and rales could be heard all over the chest. The heart rhythm was regular and the apex beat one inch further out. Both lung bases were dull to percussion. The venous pressure was not increased. Soon after the completion of catheterization the patient became intensely alarmed and broke into a profuse generalized sweat. The heart became grossly irregular; the pulse weakened but did not increase in rate. After an injection of morphine grain 1/4 and atropine grain 1/100 the blood pressure returned to 165 systolic and 90 diastolic within ten minutes; the pulse became regular. Thirty minutes after this recovery the patient was again alarmed by a sensation of imminent death; he began to sweat, the systolic blood pressure fell sharply from 155 to 135 and then to 30 mm. Hg; the pulse was irregular and he died in a few seconds.

(1) At death. (2) Fibrinogen 0.4 gramme. (3) Direct van den Bergh negative, bilirubin 0.8 mg. (4) Received 1,000 c.cm. saline. (5) Calcium 10.6 mg. (6) Uric acid 10 mg. Creatinine 4 mg.

The biochemical findings are recorded in the appended table and are shown graphically, in conjunction with the fluid balance, pulse rate, and blood-pressure readings, in the chart.

POST-MORTEM FINDINGS

Necropsy was performed sixteen hours after death. The macroscopic appearances were as follows: *Kidneys*—Swollen; the cortex was very pale and there were interrupted red streaks in it. The weights of the kidneys were: right 6 oz., left 8 oz. *Heart*—All chambers were full of fluid blood. Otherwise the heart appeared normal. Weight 12 oz. *Aorta*—The aorta was normal except for slight atheromatous change. No thromboses in iliac, femoral, or popliteal vessels. *Muscle*—The muscle in the left leg, in the crushed area, was pale and friable and showed a large number of haemorrhages. The main muscle groups affected were the peroneal group, soleus muscle, and the lower part of the vastus externus. There was a subperiosteal fracture of the left tibia. *Lungs*—Both bases were somewhat collapsed and the upper lobes showed petechial haemorrhages. The left lower lobe was completely collapsed and the bronchi were full of pus. *Liver*—Appeared normal macroscopically, though rather congested. *Spleen*—Small white areas were seen on the surface of the

spleen. These extended about 0.2 centimetre into the substance of the spleen. There was a small amount of perisplenitis on the area in contact with the kidney. *Suprarenals*—No obvious macroscopic change. *Stomach*—Very congested. Appearance of acute gastritis. No definite ulceration. *Pancreas*—Appeared normal. *Intestines*—Normal. *Bladder*—Normal. *Rectum*—Normal. *Thyroid and parathyroid glands*—Normal. *Brain*—There were a number of small (?) cystic spaces in the left posterior cerebrum. These did not appear to have any acute origin. *Pituitary*—Appeared normal. No bony damage to the skull.

HISTOLOGICAL FINDINGS

The following tissues were examined histologically: kidney, lung, liver, spleen, myocardium, pancreas, brain, stomach, voluntary muscle of leg, adrenal, thyroid, and pituitary.

Renal Changes.—The most important changes were those found in the kidneys. In these there were slight oedema of interstitial tissue and changes in the glomeruli and tubules.

The glomeruli: The capsular space was distended by material stained pink with eosin. In the majority of glomeruli this material formed either a net or a net together with a little granular material; in other glomeruli the material was globular, the masses often being about the size of erythrocytes.

Tubules: The majority of the tubules throughout the cortex and in the medulla contained material similar to that found in the glomeruli. In many tubules in both cortex and medulla there were casts of granular brown material, and in some a few clumps of erythrocytes.

In frozen sections no trace of fat was found either in the tubules, cells, or capillaries. These sections did, however, show that the pink material in the tubules and glomeruli filled the spaces more completely than it appeared to do in the paraffin sections. Many stains were tried in an attempt to identify the material in the tubules and glomeruli, but without success apart from a positive stain for fibrin (Weigert's fibrin stain). The material giving a positive stain appeared only in the distal part of the tubules and never in the glomeruli in this kidney. The brown material did not give a positive reaction for free iron.

Other Organs.—Spleen, myocardium, pancreas, adrenal, thyroid, and pituitary were all normal. The lungs contained focal haemorrhages, patches of oedema, and slight acute inflammatory infiltration. The liver showed parenchymatous degeneration and also oedema in the region of the portal systems with dilated lymphatics. In the stomach there were minute haemorrhages in a congested mucosa. In the brain there was a little old and recent haemorrhage in wide perivascular zones in the white matter beneath the cortex in the left temporal lobe. In the voluntary muscles of leg histiocytic reaction was found in the periphery of degenerate partly calcified muscle bundles from the thigh.

Our thanks are due to Mr. W. H. C. Romanis for permission to publish this case.

Although the activities of the National Smoke Abatement Society have had to be limited owing to the war, it has been found possible to continue some of the work and to issue publications, and the financial position is satisfactory. After a meeting held at Manchester the executive committee put forward a comprehensive resolution pointing out that in view of the need to eliminate all forms of waste, attention ought to be directed to the gross and expensive waste causing and caused by the smoke nuisance—a waste not only of fuel and power, and of money, labour, and skill, but of health and amenity; the society viewed with anxiety the deterioration in atmospheric conditions which had occurred during the war. The intensification of the war, however, soon after this resolution was framed, prevented any considerable action upon it or any campaign on the ground of fuel economy against industrial smoke. The president of the society is Dr. H. A. des Vœux, and the British Medical Association is represented on its council by Dr. G. Clark Trotter and Mr. Bishop Harman. The society's eleventh annual report has just been issued.

A CASE OF LIMB COMPRESSION ENDING FATALLY IN URAEMIA

BY

R. MAYON-WHITE, M.B.

AND

O. M. SOLANDT, M.D.Toronto, M.R.C.P.

(From the S.W. London Emergency Blood Supply Depot)

In this issue of the *Journal* (p. 427) Bywaters and Beall report four cases of renal failure in air-raid casualties, three of which received blood transfusion. The pathology of these cases is very similar to that resulting from incompatible blood transfusion. The following case is reported because, though it is clinically similar to and in its essential pathology identical with the cases of Bywaters and Beall, there is the vital difference that blood transfusion played no part in its treatment.

Case Report

A girl aged 11 was pinned under bomb debris for about three hours on a night of October. Members of the rescue party stated that she was lying on her right side, body tilted head downwards at an angle of 45 degrees, the legs acutely flexed at hips and knees. In this position she was compressed, though not actually crushed, by the dead bodies of her parents; a heavy beam lay upon her left thigh.

On admission to hospital she was conscious and rational as she had been all the time rescue work was proceeding. Though rather pale and complaining of pain in both legs, she seemed comparatively unhurt. Full examination revealed no evidence of injury save some swelling of the left thigh. The blood pressure was not taken, but the pulse was said to be of normal rate and fair tension. During the early morning she passed 4 oz. of smoky red urine which was said to have given a positive result to the tinct. guaiac. test for blood. Radiography showed no evidence of bone injury. The swollen thigh was thought to be due to a deep-seated haematoma from injured muscle.

Next night she was first seen by one of us (O. M. S.). She presented a typical picture of uraemia. She was drowsy and irritable, her skin was dry, her respiration deep and sighing. Her mouth was dry, the tongue covered with brown fur, and the lips cracked. The left thigh was very much swollen, pitting oedema extending from the hip to the toes. The greatest swelling was in the thigh; there was no discoloration of the skin to suggest an underlying haematoma. The left arm was also oedematous. During the next five days the oedema increased and spread till the whole body below the level of the nipples showed pitting on pressure; the swelling was always greater on the left than on the right side. There was no oedema of the face. The patient was nursed throughout in a semi-sitting position, this being the only one she would tolerate. The bladder was never palpable. There was complete anuria save for a few cubic centimetres passed incontinently on the nights of October 30 and 31. Attempts to collect a specimen of urine by catheterization proved the bladder to be empty.

Her condition progressively deteriorated. She became more and more irritable, being much troubled by thirst and by her inability to move her oedema-bound legs. She remained conscious, though increasingly stuporous, until an hour before her death. She died at 4.30 p.m. a week after admission. At no time was the patient jaundiced, nor was there an icteric tinge to the plasma of any blood sample taken for haematological readings.

Treatment.—In an endeavour to cause a diuresis 3,000 c.c. of 5% glucose in normal saline was given by intravenous drip over a period of thirty-six hours from October 29 to 31. In view of the increasing oedema and decreasing fluid

proteins (from 6.4 to 4.8—see table), and since no diuresis had ensued, this was abandoned. Mersalyl 1 c.cm. was injected intramuscularly on October 31, and a similar dose intravenously on November 2.

Table Correlating the Treatment, Blood Pressure, Urine Excretion and Blood Estimations

Date*	Blood Pressure	Blood Urea mg. per 100 c.cm.	Hb %	Haematocrit (% R.B.C.)	Plasma Protein gm. per 100 c.cm.	Treatment	Urine Output
Oct. 28	—	—	—	—	—		4 oz.
,, 29	132/100	154	124	54.0	6.4	3,000 c.cm. 5% glucose-saline	Trace
,, 30	125/90	210	94	42.0	4.8		,,
,, 31	140/100	295	—	—	—	100 c.cm. 4×N serum	None
Nov. 1 (a.m.)	140/100	295	98	42.5	4.3	400 c.cm. 4×N serum	,,
(p.m.)	140/110	309	90	40.0	4.9		
,, 2	150/110	327	88	39.5	4.3		,,
,, 3	145/110	369	76	35.5	4.6	200 c.cm. 4×N serum	,,

To raise the plasma proteins and because of its diuretic action (Anderson and Boyle, 1940) concentrated human serum was given intravenously. The serum used was the dried serum supplied by the Medical Research Council's serum-drying unit. It should perhaps be emphasized that the serum from Group A (II), B (III), and AB (I) donors is pooled before filtration and drying, and that the effect of this pooling is to render the agglutinin content negligible (Levinson and Cronheim, 1940). A solution of four-times-normal concentration was made. Intravenous injection of 100 c.cm. on October 31, and 400 c.cm. (by intravenous drip) on November 1, produced a rise of plasma protein from 4.3 to 4.9. Coincidently the patient seemed more comfortable. A further infusion was started at 11 a.m. on November 3. 200 c.cm. had been administered by the time she died. (On this last occasion 0.5 gramme of evipan intravenously was necessary to restrain the patient while the cannula was inserted. Anaesthesia lasted twenty minutes. On November 1 sodium amytal grains 1½ by mouth was sufficient.) No reaction was caused by the serum. The patient's temperature remained subnormal throughout her stay in hospital.

Pathology

The post-mortem examination was performed by Dr. J. V. Dacie. The chief findings were as follows:

General: Symmetrical oedema of body from nipples to feet. Arms oedematous below mid-point of humerus.

Thorax: No excess of fluid in pleural cavities. Slight excess of clear fluid in pericardium. Heart normal. Fluid blood in great vessels.

Lungs: Pale and bulky. Slight basal congestion (detached portions floated in water).

Abdomen: Slight excess of peritoneal fluid. Stomach, liver, spleen, and mesentery normal. Considerable injection of the mucous membrane of the bowel from the duodenum to the sigmoid colon. Kidneys large and pale, foetal lobulations well marked. On section the kidney cortex seemed paler than normal. The differentiation between cortex and medulla was very clear. The capsule stripped readily. Ureters normal, bladder empty. No other abnormalities were found.

Thigh muscles: Oedematous but otherwise normal. No extravasation of blood, no microscopical evidence of necrosis.

It is the microscopical appearance of the kidney that is the chief point of interest in this case. Most of the tubules contained a granular debris that stained a brick-red colour with eosin. This material could be found in all parts of the tubule from the capsular space to the duct of Bellini. Proximally it was small in amount and was often embedded in an albuminoid substance, but in the collecting tubules the granules were tightly packed, forming a solid cast of the lumen. At first sight some of these granules seemed to be red blood corpuscles; on closer inspection and comparison with intact corpuscles in the vessels it was evident that the tubular contents were frankly granular, though "ghosts" of broken cells could be seen in some places. In an unstained section the tubular contents were the golden-red colour of unstained red cells. The tubular epithelium in some places showed evidence of degeneration. Some of the cells had lost their outline. There were some pyknotic nuclei. This degeneration seemed to bear no constant relation to the amount of material in the tubule. The glomeruli were normal; the capsular space was not dilated. Special staining showed no fat and no free iron in the kidney substance or in the tubules.

Summary

The case is reported of a patient who died from uraemia following a type of injury that often produces shock. The micropathology resembles that of incompatible transfusion. Unlike similar cases reported in this issue there can be no possibility here of incompatible transfusion, since no blood was given to our patient. Herein lies the importance of this case and the reason for reporting it.

We wish to thank Dr. A. T. Moon for allowing us access to his patient and Dr. J. V. Dacie for performing the necropsy and preparing sections of the kidney and other organs

ANTIBODY RESPONSE AND SYSTEMIC REACTIONS AFTER INOCULATION OF A NEW TYPE OF T.A.B.C. VACCINE

BY

A. FELIX, D.Sc.

S. G. RAINSFORD, M.D.

Surgeon Commander, R.N.

AND

E. JOAN STOKES, M.B., B.S., M.R.C.P.

(From the Emergency Public Health Laboratory Service, the Royal Naval Medical School, and University College Hospital)

An account was given in last week's issue (p. 391) of the experimental work that led to the preparation of a new type of typhoid vaccine killed and preserved with alcohol. The object of the present paper is to record the results of comparative trials in man, carried out with the new and the old types of vaccine. Observations were made on the local and general reactions produced by the inoculations, and the immunity response was measured by the estimation of the Vi and O antibody content of the sera.

From the experiments described in the preceding paper it seemed justifiable to expect that alcohol-killed and alcohol-preserved vaccines would stimulate Vi antibody response in an outstanding manner and could, by this property, be distinguished from ordinary heat-killed and phenolized vaccines. To test this point, and also to ensure the unbiased reading of the agglutination tests, the first three trials were so arranged that the samples of serum reached one of us (A. F.) labelled only with serial letters and numbers, without indicating which of the vaccines tested had been used for the inoculation of any particular group of volunteers. It will be seen from the following tables that in each of the three trials the group

suspended in buffered formalin–saline solution (Felix and Gardner, 1937). The sensitiveness of the suspensions was in each test checked against standard O agglutinating sera. The serum samples from the naval recruits were tested independently by two of us (S. G. R. and A. F.), using the same batches of suspensions and standard sera and the same technique. Thanks to this precaution the results obtained by the two observers were in good agreement.

The following serum dilutions were tested for O antibodies against the various suspensions:

Bacterial Suspensions	Sample of Serum taken before Inoculation	Sample of Serum taken after Inoculation
Bact. typhosum	1 : 50 1 : 100 1 : 200	1 : 50 1 : 100 1 : 200 1 : 500 1 : 1,000 1 : 2,000
Bact. paratyphosum B		
Bact. paratyphosum A	1 : 25 1 : 50 1 : 100	1 : 25 1 : 50 1 : 100 1 : 200 1 : 500 1 : 1,000
Bact. paratyphosum C		

In order to detect even a very slight increase in O antibody content the titre was assigned to the highest dilution of the serum which showed a "last trace" reaction, visible by means of a magnifying lens. Any difference in titre between the two corresponding samples of serum that amounted to one dilution in the series tested—i.e., an increase of 100%—was taken as "significant." With this very sensitive method of measurement the high figures of "significant" reactions that have been recorded in Tables I, II, and III were obtained.

No attempt was made to express the degree of antibody response in terms of average titres observed in the various groups. It is well known that the ability of different individuals to produce high-titre agglutinins varies over a very wide range. Groups comprising much greater numbers than those tested in these trials would be needed to counteract the effect of individual differences and to produce statistically significant figures. Most of the titres observed with the two sensitive suspensions TO and BO varied from 1 in 100 to 1 in 500, only very few reaching or exceeding a titre of 1 in 1,000. With the less sensitive paratyphoid A and C suspensions the O titres usually varied from 1 in 25 to 1 in 100, and very rarely reached or exceeded 1 in 200.

The readings of the O agglutination tests were taken after two hours' incubation at 37° C., and a further twenty-two hours at room temperature. It was found that O agglutinins of titres as low as those occurring in the serum from inoculated subjects do not withstand prolonged heating at 50° to 52° C., the temperature usually employed for incubating diagnostic agglutination tests. It is known from earlier work (Eisenberg, 1906) that diluting the serum increases the heat resistance of agglutinins, and this is of particular importance in the case of the O agglutinins, which are less resistant to heat than H agglutinins (Felix and Olitzki, 1929). Many of the O reactions recorded in Tables I, II, and III as positive would have been missed had incubation at 50° to 52° C. been employed.

Technique of Typhoid Vi Agglutination Tests

The Vi agglutination tests were carried out with a batch of suspension prepared by Lieut.-Colonel R. F. Bridges at the Standards Laboratory, Oxford, using the sensitive strain Vi I of Bhatnagar (1938). The agglutinability of the suspension was checked against the provisional standard serum which was described in connexion with the standardization of therapeutic anti-typhoid serum (Felix, 1938). It was soon found, however, that the standard of agglutination chosen in that work, and employed also in diagnostic Vi tests to indicate the Vi titre of a serum, was too high for the measurement of Vi antibodies of titres as low as those induced by T.A.B.C. inoculation. A lower standard had therefore to be adopted for the purposes of this investigation. This was chosen at half the original value, so that the standard agglutination which determined the Vi titre was that occurring in the dilution 1 in 1,200 of the provisional standard serum. The degree of this reaction with the suspension that was employed throughout this investigation was a full reading estimated with the naked eye.

The two corresponding samples of serum taken from eac volunteer before and after inoculation were tested against th Vi suspension in the dilutions 1 in 10, 1 in 20, 1 in 40, an 1 in 80, and any increase in titre of 100% or more was cor sidered as "significant." In the series of 227 naval recrui recorded in Table III 34 significant Vi reactions were foun The following titres were observed: 15 had titres of 1 in 1(11 of 1 in 20, 7 of 1 in 40, and 1 of 1 in 80.

Local and General Reactions

The reactions following the administration of th alcohol-killed and alcohol-preserved vaccine were com pared with those produced by the other batches of vaccin employed in the trials. Notes were made separately o the reactions following the first and second doses o vaccine. Records were kept of temperature readings take during the first two days after the injections and of th occurrence of any of the symptoms that are associate with T.A.B. inoculations. Under local reactions th diameter of erythema and the degree of tenderness wer recorded, and special attention was paid to involvemen of axillary glands and to any serious complaints o inability to use the arm.

In the course of the three trials described in the pre ceding sections, and in a few others not hitherto mentioned about 140 adults were given alcohol-killed and alcohol preserved vaccine in doses of 0.5 and 1 c.cm. About 10(of the inoculated were men and 40 were women, including 20 nurses. It was soon found that the reactions produced by the new type of vaccine differed in two respects from those caused by ordinary vaccine.

(i) *General Reactions.*—There was a remarkable absence of severe general reactions. Temperatures over 99° F. were recorded in a number of cases within twelve to twenty-four hours, especially among the female volunteers, but the slight malaise was transient and did not cause the nurses to go off duty.

(ii) *Local Reactions.*—The injection is felt as a sting lasting for a fraction of a minute. This is due to the alcohol contained in the vaccine. The early local reactions, consisting of erythema and swelling, were similar to those produced by ordinary T.A.B. vaccine, though they were usually milder and rarely involved the axillary glands. As a rule there was no pronounced muscular stiffness and the arm could be used freely. The inoculated naval ratings, for instance, did not require to be excused duty, which included physical training. The redness and swelling persisted for two or three days and then subsided rapidly, but a small palpable nodule was left in most cases, and this persisted for about ten days before passing off gradually. In some cases the nodule, about the size of a split-pea, could still be felt after three weeks.

In 3 cases out of 140 that were given the customary large doses of vaccine the local reaction has been different— in 1 male and 1 female after the first dose (0.5 c.cm.) and in 1 male after the second dose (1 c.cm.). In these cases there was some local induration, which appeared about the fourth day after the injection and by the sixth day had developed into a small fluctuating area at the site of the injection. This delayed local reaction was not accompanied by any general reaction, did not interfere with the free use of the arm, and disappeared spontaneously in the course of two or three weeks.

The alcohol-killed and alcohol-preserved batches of T.A.B. and T.A.B.C. were the only vaccines that produced the subcutaneous nodule. The vaccine which was killed by alcohol but suspended in saline containing 0.5% phenol (see batch P in Table III) produced both general and local reactions of the type seen after inoculations of ordinary heat-killed vaccine. There can be little doubt, therefore, that the alcohol that is injected with the vaccine is in

some way responsible for the modified reaction. Rabbits inoculated subcutaneously with alcoholized vaccine develop similar nodules. It is possible that histological examination will suggest an explanation of how alcohol and bacterial toxins, when contained in the vaccine, combine to produce the lesion. The absence of more severe general reactions is probably due to the fact that the absorption of toxic substances from the bacterial bodies is delayed as a result of the action of alcohol.

Antibody Response and Severity of General or Local Reactions

Some workers hold the view that the severe reactions that occur after inoculations with ordinary T.A.B. vaccine are of value in enhancing antibody production and thus are not wholly a disadvantage. Ramon's (1926) method of producing artificial sterile abscesses in horses undergoing immunization in order to increase the amount of antitoxin in their blood is sometimes quoted in support of this view. It has been mentioned already that according to Bensted (1940a) ordinary T.A.B. vaccine occasionally stimulates a certain amount of Vi antibody, though it is demonstrable only during a very short period after the inoculation. Bensted found such results solely in men who had suffered from a very severe reaction after receiving a dose of ordinary T.A.B. vaccine.

We have searched very carefully for a possible correlation between Vi antibody response and severity of general or local reactions but have failed to detect any evidence of such correlation. Tables II and III show a few instances of a significant Vi antibody response in subjects inoculated with different batches of heat-killed vaccine. The persons who had these significant Vi titres were, however, not among those who had developed the most severe general or local reactions. The numerous significant Vi reactions that were found amongst the volunteers inoculated with alcoholized vaccine also did not suggest any relation between typhoid Vi antibody and severity of reactions. The same was true with regard to the titres of O antibodies against the four bacterial species tested. Nor was there any constant relation between significant Vi titres and high O titres, or between high O titres for one particular bacterium and those for one or more of the other types.

It seems therefore to be safe to conclude that the severe reactions caused by the ordinary T.A.B. vaccine are not only undesirable, for a variety of quite obvious reasons, but are of no value as a factor contributing to good immunity response. It has been shown in Tables II and III that the alcoholized vaccines, which produced the subcutaneous nodule, were in respect of O antibody formation not superior to any of the other vaccines. It has not yet been established whether the presence of the nodule has any effect on the persistence of demonstrable O or Vi antibodies. This point is now being investigated.

Experiences with Smaller Doses of the New Vaccine

Those who have had personal experience of T.A.B. inoculation of large groups of civilians have long formed the opinion that the doses of 0.5 and 1 c.cm. of vaccine of the usual strength that are employed as standard doses for members of the armed Forces are too large for the less robust average adult civilian. Even half these doses may cause severe reactions, as has been recently stated by Bensted (1940b). Reduced doses of vaccine, carefully graded according to age, sex, body weight, and physical condition, must be employed in the mass inoculation of the civilian population if unduly severe reactions are to be avoided.

Very few data have been published to show the effect on antibody response of reducing the dose of T.A.B. vaccine. Henderson Smith and Brooks (1912) showed that, up to a point, antibody response increased with increase of antigen. More recently Topley (1930) demonstrated in experiments with paratyphoid B bacilli in rabbits that a relatively large increase in the dose of antigen administered resulted in a relatively much smaller increase in the amount of antibody produced. Since, however, these experiments were concerned only with H agglutinins, the results are not necessarily applicable to O or Vi antibody response following administration of T.A.B. vaccine. Our own observations so far consist only of two preliminary trials on small groups, while comparative trials on a larger scale are at present in progress. The results of the preliminary tests, for what they are worth, are illustrated in Tables V and VI.

TABLE V.—*Showing Effect on O and Vi Antibody Response of Reducing the Dose of Vaccine*

T.A.B. Vaccine Batch No. 2 Killed and Preserved with Alcohol			Interval between 1st and 2nd Injections	No. Inoculated	Percentage Frequencies of Significant Increase in Agglutinin Titres 10 Days after Second Dose			
Stored at 1° to 2° C. for	1st Dose (c.cm.)	2nd Dose (c.cm.)	(Days)		TO	BO	AO	Typhoid Vi
6 months	0.5	1	10	22 adult males	90.9	90.9	59.0	22.7
"	0.25	0.5	14	20 adult females	70.0	75.0	50.0	20.0

The two groups recorded in Table V consisted of adult mental patients. It will be seen from the table that the reduction of the doses to half the amount was followed by a noticeable drop in O antibody response. The low figure for the Vi antibody showed no significant change.

TABLE VI.—*Showing Effect on O and Vi Antibody Response of Reducing the Dose and Prolonging the Interval between the Injections*

T.A.B.C. Vaccine Batch A Killed and Preserved with Alcohol			Interval between 1st and 2nd Injections	No Inoculated	Percentage Frequencies of Significant Increase in Agglutinin Titres 14 Days after Second Dose			
Stored at 1° to 2° C. for	1st Dose (c.cm.)	2nd Dose (c.cm.)	(Weeks)		TO	BO	AO	Typhoid Vi
3 months	0.5	1	1	5* adult males (naval ratings)	84.2	87.7	84.2	40.3
6 "	0.2	0.4	2	19 adult females (nurses)	57.9	57.9	36.8	36.8
6 "	0.2	0.4	3	20 adult females (nurses)	90.0	75.0	75.0	35.0

The first group recorded in Table VI is identical with the fourth group shown in Table III, and has been included here for purposes of comparison. The table shows that the reduced doses given at two weeks' interval produced a much lower O antibody response than the full doses at one week's interval. The response was greatly improved by increasing the interval between the injections from two to three weeks. Again there was no significant difference in the figures for the typhoid Vi antibody.

These results seemed to indicate that the doses cannot be reduced drastically without a corresponding decrease in the immunizing effect produced, but that, up to a point, the effect of decreasing dosage can be counterbalanced by increasing the interval between the injections.

So far, reports have been received on the reactions observed in about 250 adult females and 150 adult males who were given reduced doses of the alcoholized T.A.B.C. vaccine. Adult males received 0.25 c.cm. of vaccine

followed by 0.5 c.cm., and adult females had 0.2 c.cm. followed by 0.4 c.cm. Among 210 inoculated nurses only 3 had to go off-duty after the first dose of vaccine, none after the second dose. No case of delayed local reaction was observed amongst the 400 subjects who had been inoculated with the reduced dose of vaccine.

Suggested Doses and Recommendations for the Administration of the Alcoholized Vaccine

The alcoholized T.A.B.C. vaccine is equivalent in composition and total bacterial count to the customary vaccine—i.e., it contains 1,000 million *Bact. typhosum* and 500 million each of *Bact. paratyphosum* A, B, and C per c.cm. The following doses of this vaccine are recommended:

	First dose	Second dose
For adult males	0.25 c.cm.	0.5 c.cm.
For adult females	0.2 ,,	0.4 ,,
For children (male or female):		
From 16 to 18 years	0.2 ,,	0.4 ,,
,, 13 to 15 ,,	0.1 ,,	0.2 ,,
,, 9 to 12 ,,	0.05 ,,	0.1 ,,
Under 8 ,,	0.05 ,,	0.05 ,,

These are maximum doses and should not be exceeded: the next smaller dose in the series is advised for subjects in each category who are below average in physical vigour or development.

The interval between the two injections should be three weeks. If this cannot be adhered to and the choice is, say, two weeks or four weeks, it is preferable to choose the longer interval. Revaccination is advisable one year after the primary immunization: a single dose of the size of the first dose mentioned above is sufficient.

General reactions—i.e., languor with slight fever—are as a rule either absent or quite trivial after the small doses of vaccine. If the precaution is taken to make the injections as late as possible in the day—preferably not earlier than six hours before bedtime—any general reaction will go unperceived and only a very small proportion of inoculated subjects will find themselves unfit for work on the following morning.

The local reaction is hardly ever of such a degree as to prevent free use of the arm. This is equally true of the delayed reaction mentioned previously, which was observed in 3 out of 140 subjects who had been given the large dose of vaccine. So far this type of local reaction has not yet been seen in any subject who received the reduced dose of vaccine. It is to be expected, however, that certain persons who are especially susceptible may develop a small fluctuating area even after the injection of a small dose. No treatment of any kind is necessary or advisable for such a local reaction. It is nevertheless emphasized that the quantity of vaccine injected as the second dose must not be increased in these cases. Such susceptible subjects should receive as their second dose only half the quantity of vaccine injected as the first dose.

Summary

A new type of typhoid-paratyphoid vaccine, killed and preserved with alcohol, was compared with ordinary heat-killed T.A.B. or T.A.B.C. vaccine from various sources. Two marked differences were found between groups of subjects inoculated with the two types of vaccine: (1) The alcohol-killed and alcohol-preserved vaccines stimulated demonstrable typhoid Vi antibodies in a relatively high proportion of cases, whereas the Vi antibody response to ordinary vaccines was almost negligible. No significant difference in O antibody response was observed. (2) The reactions produced by the alcoholized vaccine were much milder than those caused by ordinary vaccine. General reactions were as a rule either absent or quite trivial. The local reaction was of a modified type and hardly ever prevented free use of the arm.

No correlation was found between Vi or O antibody response and severity of general or local reactions.

Recommendations are made with regard to the dose of vaccine and the interval between the two injections.

This investigation was made possible by the co-operation of Air Vice-Marshal H. E. Whittingham, Director of Hygiene, Air Ministry; Captain M. O. D. Ellwood, D.S.O., R.N.; Surgeon Commander T. G. B. Crawford, M.B., R.N., and his staff; Prof. H. P. Himsworth of University College Hospital Medical School; Dr. Nora Archer of the City Isolation Hospital, Headington, Oxford; Dr. M. L. Rosenheim and Dr. J. F. Stokes of University College Hospital, London. We are glad of this opportunity of thanking all of them for their help and the many volunteers for their kindness.

Clinical Memoranda

An Unusual Injury to the Larynx

The injury in the following case seems to be unusual enough to be worth recording.

CASE REPORT

One night during the black-out a constable, after leaving a brightly lit police station, collided with a pillar-box in the street. The upper edge of this obstruction struck him on the thyroid cartilage. At once he experienced pain in the front of the neck and his voice became husky. The degree of huskiness gradually increased, reaching a maximum four hours after the accident. The next day his voice was still very rough, and there was tenderness to the left of the laryngeal cartilages. An examination of the larynx revealed the presence of a sausage-shaped haemorrhage under the mucosa of the left ventricular band. This haematoma almost completely obscured the view of the left vocal cord, though the extreme edge of this structure became visible when the cords were in full adduction. The possibility of a recurrent laryngeal nerve lesion was eliminated by the fact that both cords moved normally. The condition remained stationary for four days and then gradually improved. On the following day—that is, five days from the infliction of the injury—the voice still sounded deeper than usual. The haematoma was much decreased in size and the ventricular band looked purplish and swollen, but the vocal cord was clearly visible. It took twelve days for the voice to become quite normal, and in eighteen days all signs of the injury had disappeared.

Commentary.—Fatal and non-fatal cases involving injury to the neck are relatively common in police work. This particular case seems to emphasize the necessity for examining the interior of the air passages in all non-fatal medico-legal cases involving injury to the neck. Very often the assaulted person complains of pain and tenderness near or over the larynx, but apart from the tenderness that can be discovered externally there may be no concrete clinical findings that will serve as indisputable proof of injury received. Marks of finger-nails and bruising may be found externally; but this is not invariable, and the bruising may take several days to appear on the surface. In all such cases, therefore, a laryngeal examination might prove valuable.

Decisive control over mycotic infections

with the fungicide jelly

MERSAGEL

Conditions favourable to the spread of mycotic infections are multiplied beyond the normal this year. Peace-time sources of infection are far outnumbered by those which arise under conditions of communal life in the Services, in hospitals, in A.R.P., and in Rest Centres. The fungicide jelly Mersagel, has shown its value in training camps as an effective means of controlling these infections, particularly tinea of the foot, groin and axillae. Mersagel consists of phenyl mercuric acetate (1 in 750) in a colourless water-soluble jelly base. Mersagel rapidly destroys the causative organisms, soothes the inflamed skin, and assists healing. It is simple to carry and to apply. Mersagel is available in collapsible 1½ oz. tubes and 16 oz. jars.

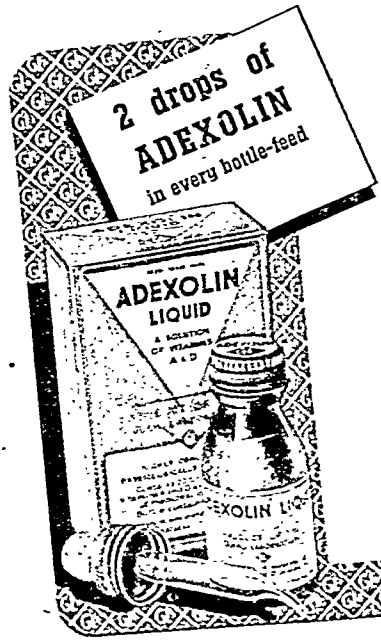
PRODUCTS OF THE GLAXO LABORATORIES

Acriflavine made fully effective

potent, soothing

prolonged action

Acriflavine enjoys a high reputation as a powerful tissue antiseptic. But in its new form—Flavogel—acriflavine is even more effective. Presented in a bland jelly base, soluble in water, the acriflavine in Flavogel can penetrate immediately to every part of the wound. Working *mutually* with the tissues it exerts full bactericidal action, with a markedly prolonged effectiveness. Flavogel reduces swelling round the wound, promotes clean and rapid healing, prevents re-infection and is soothing in application. Flavogel is offered in tubes, an advantage that marks it as particularly suitable for inclusion in A.R.P. and other emergency first-aid kits



1½ oz. tubes and 16 oz. jars

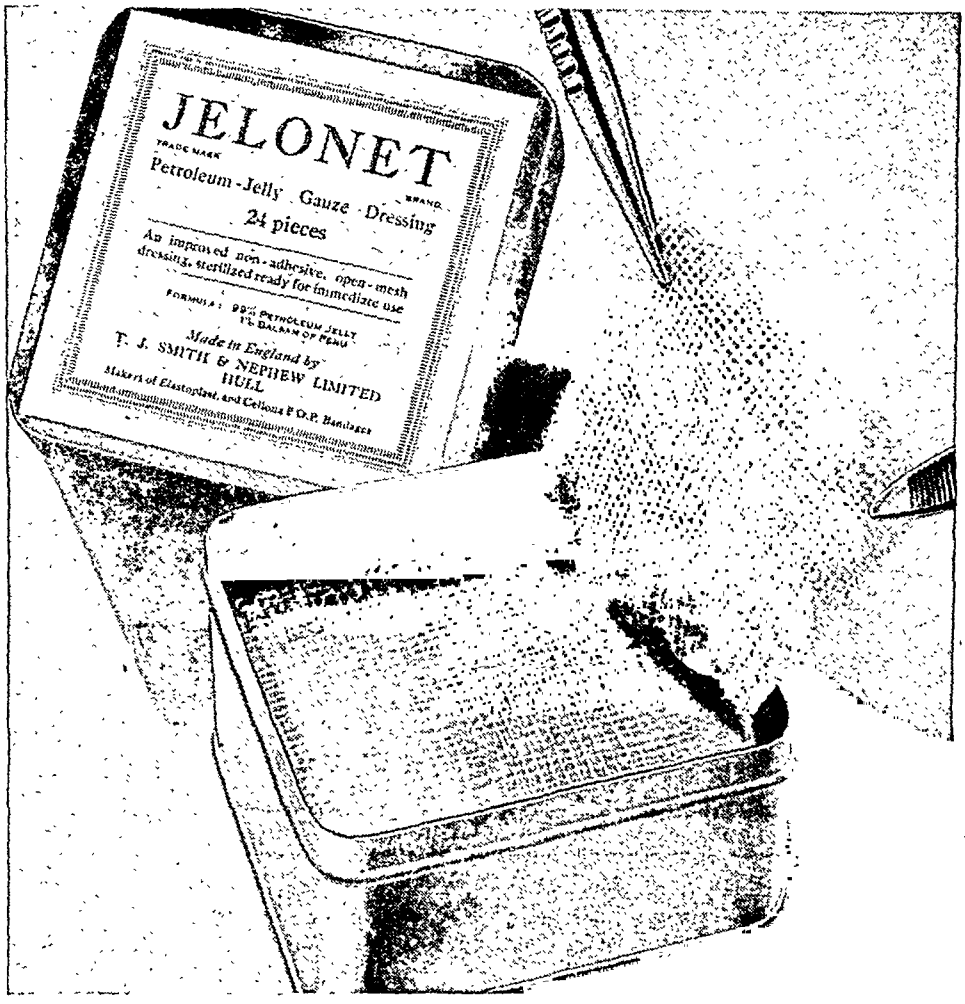
Vitamin routine for every infant

Just as the infant is protected against vitamin C deficiency by a routine ration of orange juice, so he should be provided with extra vitamins A and D by means of some independent standardized preparation. This provision is a wise precaution for all infants, whether bottle-fed or breast-fed. In bottle-feeding the supplement is particularly advisable when liquid or whole dried milk is used. In breast-feeding it is a safeguard to the infant who may be suffering from a maternal dietary deficiency of these vitamins. A daily ten drops of Adexolin Liquid effectively satisfy the infant's dietary needs of vitamins A and D and build a valuable reserve. Powerful assistance is given to normal growth, to dental and skeletal development, and to resistance against infections. Being virtually tasteless, Adexolin Liquid can be given unnoticed in the bottle-feed, or in fruit juice—or even on the infant's tongue.

A 14cc. phial of Adexolin Liquid, costing 2/-, yields 490 drops—sufficient for nearly seven weeks. Even more economical are the 2 oz. bottle (6/-), the 4 oz. (10/-), and the 8 oz. (18/-). Prices and applicable in Eire are subject to usual professional discount.



ADEXOLIN

LIQUID vitamins A and D for growth and well-being

Each cc. contains 12,000 i.u. of vitamin A and 2,000 i.u. of vitamin D—the equivalent of 10 cc. of medicinal cod-liver oil.

PRODUCT OF THE GLAXO LABORATORIES

Glaxo Laboratories Ltd., Greenford, Middlesex. BYRon 3434

'JELONET' PETROLEUM-JELLY GAUZE DRESSING is made from a specially woven open-mesh gauze, evenly saturated with petroleum jelly and Balsam of Peru, and is packed in sealed containers of 24 dressings, sterilised ready for immediate use.

'Jelonet' is indicated for Skin-Grafts, Compound Fractures, Burns, etc., as a non-adherent dressing to promote granulation. The open-mesh dressing encourages free escape of discharge, and ensures ventilation for skin-grafts and young epithelium, with minimum trauma to granulations.

Uniform saturation with petroleum jelly prevents serious rise of temperature due to toxic absorption, secondary dermatitis of the surrounding skin arising from irritating discharge, and also permits ready extrusion from deep wounds

Obtainable through your usual Surgical Supplier, 5/2d. per tin of 24 dressings. Special prices available to Hospitals. Made by the makers of 'Elastoplast' and 'Cellona.'

An Advanced Case of Cerebrospinal Fever

Remarkable recoveries from cerebrospinal fever are often observed with modern methods of treatment. The following account of a case of unusual severity may be of interest because the patient was completely restored to health although he had been moribund and paralysed for a considerable period.

CASE HISTORY

On May 28, 1940, an Italian café proprietor aged 42 was admitted to hospital. For ten days before admission he had a severe headache, with pyrexia on the third day, and for two days before admission he was comatose.

On admission the patient obviously was desperately ill. The respirations were Cheyne-Stokes in character, the rate being 28. There was no fever. Pronounced neck retraction and a right-sided hemiplegia were present. Lumbar puncture showed the cerebrospinal fluid pressure to be 260 mm., and 20 c.cm. of thinly turbid fluid was withdrawn from which meningococci were cultivated.

Sulphapyridine was given immediately. The dosage is shown in the accompanying table. After twelve hours the

Table of Treatment

patient was even worse, and a further lumbar puncture was performed. The pressure was again 260 mm., and 10 c.cm. of fluid was removed; this time it was flocculent. Fluids were administered intravenously, as the man was very dehydrated and it was considered that this fact might be contributing to his grave condition. On May 29 daily intramuscular injections of anti-meningococcal serum were begun, being continued for the next eleven days. Vitamin B_1 was injected daily in doses of 10 mg. for about three weeks, when the dose was diminished to 2 mg.; this treatment was continued until full recovery occurred. The frequency with which lumbar puncture was performed is shown in the table. On the fifth day after admission the cerebrospinal fluid pressure was approximately normal and the fluid was clear.

By the end of the first week of his stay in hospital the patient showed no sign of return of consciousness and the respirations were still grouped; a few days later he developed bronchopneumonia. During the second week, while the temperature, pulse, and respirations were still raised on account of the chest condition, indications of improvement were observed: at times during the day he would take notice of what was going on around him. It was considered that recovery might be encouraged if he were given a blood transfusion. Accordingly 500 c.cm. of fresh blood was administered, following which daily improvement was observed. Some days before he began to talk his sense of humour returned. He now became aware of his incontinence, and this was the first step towards its control; then the plantar response on the right side became flexor and the leg showed signs of returning function. The hand was the first part of the upper limb to manifest improvement, and a week later the shoulder muscles, encouraged by massage, followed suit. After six weeks he could walk with help and sign his name with a rather childish hand. When last heard of he was completely restored to his normal health.

I am indebted to Drs. A. C. Hampson and W. S. Hunt for permission to publish this case.

Late Resident Medical Officer, Bromley and District Hospital.

Pulmonary Tuberculosis in Soldiers

The admission of men with pulmonary tuberculosis to the Army is of extreme importance from both the economic and the hygienic points of view, and therefore analysis of the data from the first 100 cases personally examined and "boarded" out of the Army may be of interest, especially in regard to evidence of disease previous to entry and likely factors in causing promotion or exacerbation of symptoms.

The age incidence in this series was: 9 patients under 20 years, 78 from 20 to 30, 9 from 30 to 40, and 4 over 40. Of these, 22 gave a history of active pulmonary tuberculosis in members of the immediate family circle—mother, father, brother, sister, or wife.

There was clear evidence that 18% had been in sanatoria and 15% more were suffering from the disease previous to admission to the Army. In 41% the condition was manifest within a month of recruitment, another 11% within three months, 16% in six months, 16% within a year, and only 16% first showed symptoms after a year. The value of medical supervision and weight recording in the first three months of Army life is therefore obvious. Cooper (1940) says that 5% of recruits to the 6th Division of the A.I.F. were turned down by medical boards on account of phthisis and that another 0.9% were later discovered by microradiography, of which over half appeared to be active. These figures bear out the importance of the recommendations of the Committee of the Ministry of Labour and National Service (1940), presided over by Lord Horder, that (1) medical boards should obtain from recruits a signed statement that to their knowledge they have never suffered from pulmonary tuberculosis; and (2) that district medical officers of health should (*a*) furnish all men likely to be called up, and known to be suffering from phthisis, with a certificate to that effect, and (*b*) notify the Ministry of Health of this fact, so that medical recruiting boards might have this information before them.

Analysis of the clinical records of the 100 cases shows that 15 had a definite past history of pleurisy and that in 22 the onset of the condition was made manifest by an attack of pleurisy. In 27 haemoptysis was the first symptom, in 29 cough, in 16 general symptoms of lassitude, loss of weight, etc.; in 7 the onset was acute and was first mistaken for pneumonia, and in 3 the main symptoms were gastric, the cases being sent up to the medical specialist clinic as suffering from peptic ulcer. In addition 1 came under attention with tuberculide, 1 with ischio-rectal abscess, and 1 was diagnosed when admitted for acute appendicitis. When medically "boarded" out of the Army 42 of the men had bilateral and 41 unilateral infection, the right lung being affected slightly more often than the left. In 48 of 78 cases the sedimentation rate was definitely increased, and in only 2 cases in which the sputum was loaded with tubercle bacilli was the sedimentation rate under 10 mm. Westergren at the end of one hour.

Factors in causation suggested by the men were: prolonged exposure to severe weather and damp, 32; heavy work and lack of sleep, 32; poor ventilation due to black-out and housing difficulties, 14; and difficulty in obtaining adequate food (in Belgium), 10. 31 of the men could find no exception to any condition under which they had had to work.

BOVINE TUBERCULOSIS

Man's Greatest Victory over Tuberculosis. By J. Arthur Myers, Ph.D., M.D., F.A.C.P. (Pp. 419; illustrated. $5.00 post paid or £1 7s. 6d.) Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox. 1941.

A wealth of medical and scientific knowledge has been assembled to prevent, diagnose, and treat tuberculosis. The disease is no longer solely one of medical significance and relegated entirely to the physician and surgeon. Its social and economic implications are far-reaching, and the anti-tuberculosis worker, whether he be administrator or clinician, throws his net widely and seeks aid from many quarters to combat the disease.

It is well known that a certain proportion of human tuberculosis, especially that of children, is caused by bovine tubercle bacilli, and that human beings may be infected through the ingestion of tuberculous milk or tuberculous meat. It has been estimated that not less than 40% of all the cows giving milk in England are infected with tuberculosis, so that there is every possibility of bovine infection. The proportion of cows actually yielding tuberculous milk is still probably between 1% and 2%. It is here that the veterinarian steps in to contribute his wide knowledge of tuberculosis in cattle towards preventing the disease in man. The link between medicine and veterinary medicine is an important one and mutually beneficial. This was a lesson that Sir William Osler was never tired of preaching, and he put his words into practice, for he had a teaching post at a veterinary college in his younger days, and made notable contributions to comparative pathology—for example, by his investigation of hog cholera. Sir Clifford Allbutt, also, realized the importance of epizootic disease in its relations to man, and was largely responsible for instituting a section of comparative pathology in the Royal Society of Medicine.

In tackling the problem of bovine tuberculosis the United States has obtained great success. This book by Prof. J. A. Myers of the University of Minnesota tells the story of the struggle and the triumph. The earlier chapters deal with the dependence of mankind upon domestic animals, particularly cattle, the development and progress of veterinary practice, and its value in solving important economic and public health problems. The prevention, diagnosis, and treatment of tuberculosis in cattle are discussed.

In the diagnosis of bovine tuberculosis main reliance is placed on the intradermal or intracutaneous tuberculin test. It is curious that the author makes no reference to the prolonged and careful work of the Tuberculin Committee of the Medical Research Council on this test, which is embodied in two reports, published in 1925 and 1928, or to the double intradermal method which the committee advocated. As regards the immunization of cattle against tuberculosis, Prof. Myers rules this question out of practical politics. He writes (p. 196): "Although B.C.G. and all other proposed methods of immunizing cattle against tuberculosis have been given adequate trial in North America they were found wanting and were completely discarded by the veterinary profession." So sweeping a conclusion would hardly receive general scientific acceptance, for a good deal of research work on this problem was done in this country up to the war by Buxton, Stanley Griffith, and others.

Prof. Myers gives details of the work done in the various States of the Union. He records with justifiable pride American achievement in eradicating reactors from tuberculous herds and in the building up of clean herds. Such achievement is equally possible in this country, but, as was the case at first in America, the question of expense has frightened stock-owners, although Jordan's work for the Medical Research Council has shown that good results can be secured in heavily infected herds at small cost. Prof. Myers notes that by eradication methods from 1917 to 1939 inclusive the incidence of reactors in tested areas decreased from 3.2% to 0.5%. This reduction must undoubtedly diminish the sources of bovine infection in human beings. At the same time a good deal of credit is due to the pasteurization of milk supplies, which is much more extensively done in the United States than in this country.

The final chapter of the book is entitled "Lessons for Physicians in Human Medicine." Here Prof. Myers claims that veterinarians are in advance of the medical profession. He holds that contagious tuberculosis is primarily a disease of adult life, that brief exposure to infection is dangerous, and advocates a much stricter segregation of tuberculous patients, to be enforced if necessary by legislative action.

All will not agree with Prof. Myers's conclusions, but his book is a mine of information on its subject and stimulates thought. The chief reflection it inspires is that the United States is far ahead of this country in dealing with the problem of bovine tuberculosis. This is not the fault of the British medical and veterinary professions, but because public opinion still fails to realize that much disease and suffering are brought about by drinking tuberculous milk, and legislation waits on public opinion.

WAR AND CRIME

War and Crime. By Dr. Hermann Mannheim. (Pp. 208. 10s. 6d. net.) London: Watts and Co. 1941.

A discussion of the influence of war upon crime can never depart very far from a consideration of the relationship between war and crime in general. It certainly seems as though a diminution in crime among "civilized" States ran with an increase in the ferocity of their wars. Dr. Mannheim's book indicates a great many attractive lines of thought which start from this central fact of the common factor between crime and war. He clarifies, first of all, two essential points of contrast: crime is an individual action, war a group action; crime is always a wrong, war is wrong only according to circumstances. He then inquires how far the various factors likely to produce crime may also be held responsible for the causation of war, and vice versa; and the further question of how far war itself causes crime. His final section deals with the attitude of international law as it exists to-day towards the distinction between just and unjust wars, and with analogies between war aims and aims of punishment.

Dr. Mannheim concludes that if the conception of war is restricted to unjust war, the difference between war and crime dwindles away almost to nothing. There exists accordingly a strong affinity between the causes of war and those of crime, and the methods which have been suggested for securing peace and for overcoming crime are, he points out, in many ways identical. They include institutional and social improvements, and, probably more important, psychological remedies which in their various ways canalize and deflect the aggressive spirit. In considering the influence of war on crime, he finds at first sight a contradiction. He believes, and gives plenty of evidence for the belief, that war is a potent source of crime and invariably increases the crime rate. On the other hand, he sees indications that war is sometimes a substitute for crime. At many points he finds the proba-

bility that war and crime may in some way be subject to the principle of indestructibility of matter: if either evil is discouraged in one form it may show itself in the other. Serious crimes of violence may decline owing to the competition of war as a more impressive form of violence, and they might increase if war were completely suppressed. Economic crimes, however, he finds, invariably thrive during and after wars.

His reasoning on the aspect of war as an international crime has intimate application to the present day. The dilemma with which he is confronted is that on the one hand it is vital for the upholding of decent standards of national and international morality that criminal responsibility should be extended to corporations and nations; on the other hand, criminal responsibility cannot be separated from the idea of guilt. This world is not one in which each individual can be the sole master of his acts, and so it seems hardly unfair to hold the entire community responsible for collective misdeeds which are only made possible by the support which the leader receives from the majority of the members.

This work, faithfully documented and factual as Dr. Mannheim's work always is, forms a substantial contribution to present-day sociological thought.

RADIOLOGY OF DIGESTIVE DISEASES

Clinical Roentgenology of the Alimentary Tract. By Jacob Buckstein, M.D. (Pp. 652; 525 illustrations. 50s. net.) Philadelphia and London: W. B. Saunders Company. 1940.

Recent books on *x*-ray work either deal elaborately with the technique and details of interpretation of radiographs or present a series of pictures in the form of an atlas of reference. Dr. Buckstein's volume is almost a textbook of diseases of the digestive tract written from the point of view of the radiologist. Full descriptions are given of the normal and pathological *x*-ray appearances of the whole of the alimentary canal with short notes of illustrative cases. The author treats the subject not as a specialist but as a physician who can take and interpret *x*-ray pictures, and he has made his book so readable and accurate that it may be recommended to a large public. The usual and well-known characteristics of gastric and duodenal ulcer, cancer of stomach and colon, and diverticula and ulceration of the colon are here well described; while the author's sound judgment is illustrated in his description of the care needed in assessing the progress of gastric ulcer by the amount of healing and size at the same exposure, especially the character of the edges and rigidity of the surrounding stomach wall, in the sections on the diagnosis of appendicitis, on enteroptosis and the relation of constipation and spastic colon.

This book is comprehensive enough to be of value to radiologists and students of radiology, and to the clinician it offers many admirable features. There is a useful bibliography and the illustrations are well produced.

DISEASES OF URETHRA AND PENIS

Diseases of the Urethra and Penis. By E. D'Arcy McCrea, M.D., M.Ch., F.R.C.S.I., F.R.C.S. (Pp. 306. 21s. net.) Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1940.

The publication of this book is a welcome sign of the vitality of medicine in this country even under wartime conditions. The author (whose recent death by enemy action will be in the minds of many readers) has produced a monograph on diseases of the urethra and penis which contains a wealth of material for the urologist and the general surgeon, and as such is a valuable book for the specialist. The general arrangement of the work is excellent, it is written throughout with clarity and lucidity, and it might well serve as a guide to many medical writers. The printing and the high standard of the many illustrations and drawings are of the quality which is associated with Messrs. John Wright and Sons of Bristol.

The book opens with very good accounts of the anatomy, developmental anomalies, and congenital malformations of the urethra and penis. The illustrations in these sections and in that dealing with epispadias and hypospadias are particularly valuable in elucidating the text. There is a full account of acute and chronic urethritis, their complications and treatment. The subject of urethral stricture is amply covered, its treatment well described, and the various operative procedures clearly illustrated. The various types of peri-urethritis due to extravasation of urine and acute infection, the chronic indurative type, and the rarer types due to tuberculosis, syphilis, etc., are all described in detail. Other sections of the book cover calculus and fistula of the urethra, tumours of the urethra and penis, and injuries and inflammations of the penis. Medicine and surgery in this country often have to carry on in the face of the most serious material and physical difficulties, and in this respect the Manchester urologists have had their share of difficulties. It is therefore all the more pleasurable to welcome a urological monograph of such high standard and critical outlook in wartime, but this feeling is tinged by sadness at the untimely death of the author.

Notes on Books

Electrocardiography, by Drs. C. MAHER and P. H. WOSIKA, is an elementary book intended as an introduction to the subject. The normal and the chief types of abnormal curves are illustrated by means of 100 tracings, and accompanying each are an analysis and interpretation. The figures are adequate but not first class, and the heavy time lines and horizontal 1 mm. lines impair their clearness, while the absence of any lettering on the waves makes the student's task more difficult. In one or two instances there are inaccuracies in the descriptions of the tracings, and the section on coronary disease lacks a good illustration of RS–T deviation in acute cardiac infarction. As a whole, however, this book well meets the requirements of the beginner. The third edition is published in Baltimore by the Williams and Wilkins Company, and in London by Baillière, Tindall and Cox at 22s.

Dr. DAVID FERRIMAN has written a useful monograph on *Acrocephaly and Acrocephalosyndactyly* (Oxford University Press, 10s. 6d.). It is based upon his own observations of eighteen cases of acrocephaly and an extensive investigation of the literature. The particular value of this monograph lies in the author's painstaking efforts to sort some order out of a complicated nomenclature—he asserts, for example, that Crouzon's disease (cranio-facial dysostosis) and acrocephaly are one and the same disease—and also in his insistence that treatment of a surgical nature to prevent optic atrophy must be undertaken early, certainly before the age of 5 years and probably better in the first or second year of life. Dr. Ferriman's evidence clearly points to familial transmission of the disorder almost certainly as a dominant, since one of the families investigated by him showed unquestionable evidence of the disease in three consecutive generations.

The *Dentists Register* for 1941 has now been published for the Dental Board of the United Kingdom by Constable and Co., price 12s., post free 12s. 9d. The total number of names appearing on January 1 of this year is 15,032, being twenty-two more than the figure for 1940. All the new entries added during the year were of persons registered as graduates or licentiates, and 1940 was thus the first in which no persons were registered without qualifications under the provisions of the Dentists Act, 1921–3.

VACCINATION AGAINST TYPHOID

It may not be generally known that the method of making T.A.B. vaccine has passed through several stages of development during the last ten years. The antigenic analysis of the typhoid bacillus on which these developments are based has been largely the work of Dr. A. Felix, whose paper in our last issue (p. 391) described a further stage in the refinement of this product and the theoretical basis on which it rests. With S. G. Rainsford and E. Joan Stokes he reports in this issue (p. 434) the results of practical trials of the new vaccine, and makes recommendations about the method of its use. The difference between this vaccine and its predecessors is that in a considerable proportion of individuals it stimulates the production of Vi agglutinin, an antibody which hitherto has only been known to be produced in man by actual infection. That this antibody is important is self-evident from this fact alone; other evidence of its value involves a consideration of the various methods of estimating the immunizing power of a vaccine experimentally. One of these is the active immunization test in mice, in which administration of the vaccine is followed by inoculation with varying doses of living bacilli. This test, which has been extensively employed for some years, discloses no differences in immunizing power between vaccines killed and preserved in various ways, some of which are known to destroy the Vi antigen. Passive protection tests, on the other hand, tell a different story: the vaccine is here used to immunize a rabbit or other animal, and the protective power of this animal's serum is then estimated by administration to mice together with lethal doses of typhoid bacilli; this power has been shown to depend on its Vi antibody content. This antibody is also considered to be the most important element in the new therapeutic anti-typhoid serum.

There is therefore evidence from three directions that a vaccine which stimulates Vi antibody formation will immunize better than one which does not. The next question is how to prepare a vaccine which will do this. Experience with horses used in the preparation of anti-typhoid serum shows that heat-killed vaccines have not this effect; formalinized vaccines have, but the Vi antibody formed is functionally deficient, as indicated by the results of passive protection tests in mice and the study of phagocytosis-promoting property. The only type of killed bacterial suspension found to stimulate the production of efficient Vi antibody is one treated with alcohol. The two present papers record a study of the effects of such a vaccine in the human subject. It was first shown that an alcohol-killed vaccine, made of course from virulent cultures containing adequate Vi as well as O antigen, does in fact stimulate the production of Vi antibody in a substantial proportion of immunized individuals, although by no means in all. This property, however, was lost on preservation with phenol or tricresol. Tests were therefore made with a vaccine not only killed with alcohol but preserved in it, the respective concentrations used being 75% and 25%. With this method of preservation, which is fully efficient for averting contamination, the capacity for stimulating Vi antibody formation is retained for nine months at least. Such a vaccine causes the formation of as much O antibody as an ordinary heat-killed vaccine preserved with phenol. Since alcohol destroys flagella, an alcohol-killed vaccine naturally produces less H agglutinin; it was hoped that it might produce none, since this antibody has now been degraded to the status of a mere source of confusion in interpreting diagnostic agglutination tests, but the quantity formed is sometimes such that this difficulty still exists. Alcohol-treated vaccine causes less severe reactions than the old type of vaccine—a secondary but nevertheless important point in its favour. Those who are accustomed to regard severe reactions as an accompaniment of more efficient immunization may at first sight be suspicious of this, but a study has been made in the course of this work of the possible relation between degree of reaction and extent of antibody response, and no such relation has been found. A further study of the effect of different doses on antibody response suggests that the usual doses may safely be somewhat reduced, and a longer interval between them is advised.

Presumably this vaccine will shortly be issued in place of the old type of vaccine, which has been extensively used recently, and indeed is still in use, in areas and among persons possibly exposed to an unusual risk of enteric fever. It may be long before any conclusive evidence of its protective power is obtained in the form of data on the incidence of the disease in vaccinated subjects. It is one of the major misfortunes of immunology that the typhoid bacillus should not be pathogenic for any animal in the manner in which it is for man; really appropriate tests of immunizing procedures are therefore not possible in animals. The disease itself has usually so low an incidence that for any significant test in man the numbers employed must be very large. Thus, although anti-typhoid vaccine has perhaps as sound a theoretical claim as any bacterial vaccine to be considered effective, and has certainly been more used than any other, practical proof of its efficacy is difficult to obtain. It is a somewhat disturbing thought that such proof as we have relates mainly to immunization with vaccines prepared without any regard to the nature of their antigenic content, and certainly lacking the distinctive property of the new material. In the action of the new vaccine itself there is one disappointing feature—namely, that it by no means always elicits Vi antibody production when given to human subjects in customary doses, but only in a proportion which is sometimes about one-half and sometimes less. It is possible that the method of preparation may be improved still further, and in the meanwhile all the evidence obtainable by laboratory methods indicates that progress is being made in the right direction.

CRUSH INJURY AND KIDNEY FUNCTION

Wars have a habit of throwing up new medical problems or putting old problems in a new perspective. The cases reported in this issue of fatal renal failure after burial under debris may fall into either category. In the typical case the patient has been pinned by the limbs under fallen masonry and released usually after many hours. There may be no fracture and no external wound except superficial abrasions only. These abrasions become whealed and the limb swells, while at the same time plasma constituents are lost, the haemoglobin concentration rises, and the blood pressure falls. This stage of "shock" is satisfactorily treated by transfusion of serum or of plasma. It is then found that the urinary output is falling off, often with blood casts in the scanty urine. Vomiting becomes persistent, the blood urea rises, and many patients die in the course of a few days with renal failure as the predominant manifestation.

These initial communications are concerned more with a description of the clinical, biochemical, and pathological manifestations than with any attempt to explain the underlying mechanism. Although the pathological appearances in the kidney bear a resemblance to the transfusion kidney, transfusion of incompatible blood may be excluded as a cause. The diminution of urinary output after operations has usually been ascribed to low blood pressure, but hypotension seems to have been promptly treated and transient in those crushed patients whose records are adequate. A characteristic finding appears to be the rise of serum potassium, which cannot be ascribed to the renal damage. The workers at the British Postgraduate Medical School regard muscle injury as the most significant feature in the "crush syndrome," although histological evidence of this was rather scanty in one of their cases, while Mayon-White and Solandt failed to find any. None the less, "biochemical" damage may exist without there being any gross histological manifestations, and the mass of muscle which may be involved precludes full histological examination. Oedema of the crushed area and haemoconcentration have been fairly constant events, and it is also of interest to note that the blood pressure has been high in many of the patients after the initial shock.

The publication of these case records is timely for many reasons, apart from the immediate urgency of the problems they raise. First, crush injuries to limbs may prove to be common during the course of the war, and the collected material is a useful basis on which to build up further observations on the clinical course. Secondly, attention is drawn to the importance of more careful study of kidney function in trauma of all types. It is probable that the extreme and fatal picture presented by eleven out of the sixteen cases represents one end of a scale in which there may be all gradations. Thirdly, the subject is of great interest and significance in relation to general problems of extrarenal azotaemia and renal disease. The attempts made to explain the rising blood urea of hypochloraemia, gastro-intestinal bleeding, Addison's disease, diabetic acidosis, etc., have usually invoked the idea of lowered blood volume and diminished renal blood flow. It is possible that in these cases of crush injury some other factor is operating—perhaps autolytic products liberated in dead or dying tissues. In this connexion the resemblance to the toxaemic state commonly found in concealed accidental haemorrhage in pregnancy is worthy of note. In the majority of instances the toxaemia conforms to the characteristic eclamptic picture, but, in some, suppression of urine and a rapidly rising blood urea are followed within a short time by death from renal failure. In such cases it has been shown that a large area of the detached portion of the placenta has undergone necrosis while still incorporated with the remaining placenta and its circulation.[1] There are also resemblances to the toxaemia of severe burns, in which similar biochemical changes occur in the blood.[2]

The observations that have so far been made point to the need for amplification and clarification by animal experiment, and in view of the urgency of the problem we hope that such work will be pursued with an energy appropriate to the times. On the therapeutic side there are as yet few clear guiding lines as to what should be done. In at least one instance fairly early amputation of the affected limb failed to save life, while in others recovery occurred without amputation. It therefore cannot be said that crushing is in itself an indication for removal of the limb. There is a case for the trial of suprarenal cortical hormone with careful biochemical control, although it should be noted that the suprarenals showed little change at necropsy. The situation may be clarified by further and perhaps earlier studies. It is important that crushed casualties should be admitted whenever possible to hospitals where there are facilities for full investigation. Minor crushes are of great importance, and necropsies should be performed on those patients who die soon after release. When such studies have been made, together with control observations in other types of injury and with careful animal work, we shall be nearer an understanding of this new medical problem.

TUBERCULOSIS IN WARTIME

Tuberculosis has attracted much attention since the outbreak of hostilities. There are three reasons for this. First, when war was declared tuberculous patients were discharged wholesale from institutions, without any arrangements having been made for their alternative treatment and care. Secondly, there is the fear that the well-known effect of the war of 1914–18 on the incidence of tuberculosis may be repeated to-day. And, thirdly, it is increasingly realized that men with unsuspected pulmonary tuberculosis that could be detected by mass radiological examination have been admitted into the Services. In a supplement to the August–September issue of *Tubercle*, E. L. Collis examines statistically the incidence of tuberculosis and influenza in relation to the war of 1914–18. (The value of the ten graphs accompanying the paper is unfortunately diminished by absence of captions to most of them.) He concludes that the war years 1914–18 saw the mortality from tuberculosis steadily rising, but only in early life; then "suddenly, in 1918 came the great influenza epidemic as a famine pestilence, which struck in the

[1] Young, J. *J. Obst. Gyn. Brit. Emp.*, 1914, 25, 1
[2] Wilson, W. C., MacGregor, A. R., and Stewart, C. P. *Brit. J. Surg.*, 1938, 25, 826.

same period of life previously selected by tuberculosis." Heaf and Rusby in another paper review in detail the present position of tuberculosis. They discuss the pre-war background, the period of anticipated bombing, the effort to return to normal services, mass radiography and the examination of recruits, the threat of invasion, the period of intensified bombing, evacuation and tuberculosis, nutrition and rationing, rehabilitation in wartime, medical education, and "the future." There is much in this comprehensive review that will give food for thought to all tuberculosis workers, even if they may not agree with some of the views expressed by the authors. Perhaps the picture drawn of the pre-war background is far too rosy. It is said, for example, that "the strenuous efforts of Hawthorne and Esther Carling to obtain a safe milk supply *throughout the country* [our italics] were at last reaping their reward." Although due importance is given to rehabilitation, too little is said about institutional treatment; this is still so unsatisfactory that even before the war only an insignificant proportion of sputum-positive patients were discharged as quiescent. Finally, it is said that "too scathing a criticism" would be out of place in considering the policy adopted of evacuating tuberculosis institutions to make room for air-raid casualties. But the evacuation of these institutions before alternative arrangements had been made for the treatment and care of the large number of tuberculous patients affected emphasizes how uninformed is the official attitude to this common infectious disease, the most important cause of death in adolescence and early adult life.

PROBLEMS OF DENTAL CARIES IN CHILDREN

The aetiology and prevention of dental caries are complicated, and the subject is controversial. It is clear that individual cases can prove nothing, but unfortunately for those who want to give the best advice statistical studies of large numbers of children are likely to be difficult to interpret. Such a criticism, implying a lack of statistical training in the reader, may be made of an interesting study by B. R. East and Hilda Kaiser[1] on the relation, in rural American children, of dental caries to sex, age, and environment. These workers hoped to throw some light on the part played by vitamin D in the prevention of caries by studying the mean caries rate of children living in areas where climatic and other conditions were known to produce variations in the amount of solar ultra-violet radiation at the earth's surface, or to modify the conditions of exposure. They selected three climatic variables: mean number of hours of sunshine per annum, latitude, and mean winter temperature. The incidence of caries in children in 358 rural or semi-rural counties of twenty-four States of the U.S.A. was taken from data collected under the direction of the American Dental Association and the U.S. Public Health Service. Rural children were chosen for study because it was thought that they would be ethnologically more uniform than city children. White children only were studied, in order to exclude so far as possible the variable which cutaneous pigmentation might introduce. The caries rate at three different age periods (6 to 8, 9 to 11, and 12 to 14 years) for each sex was correlated with each of these climatic variables, and from a calculation of the correlation coefficient it is concluded that a statistically significant association could be established. But since the climatic variables were to some extent dependent on each other, it was desirable to measure the relation of the caries rate and each of the independent variables free from the influence of the remaining two. This was achieved by the statistical device of a partial regression equation. From this it is seen that the relation of dental caries to latitude and sunshine is what might be expected from the measures of ultra-violet solar radiation if vitamin D is an aetiological factor in caries. The greater the amount of sunshine available at a given place the lower is the caries rate. The more northerly a county the higher is the caries rate of the children. It appears that when the overlapping influences of sunshine and latitude are separated out there is little relation of winter temperature to caries rates except in the oldest and youngest groups of girls. The suggestion is made that the younger girls are more likely than their brothers to be kept indoors when the weather is cold and that the older girls in country districts are likely to have indoor duties. Apart from these speculations, the facts and the statistical conclusions drawn from them seem to establish very clearly an environmental factor in the aetiology of dental caries; they point the way to at least one method for preventing and controlling this disorder—the supply of sunshine, natural, artificial, or "bottled," as a vitamin D supplement. A recent statistical study in these columns[2] enabled Irene Allen to point to another factor. She was able to show a fairly high negative correlation between the increase in the average caries figure at 5 years of age and the increase in the nutrition figure. That is to say, at this age the greater the increase in a specially chosen nutrition index (indicative of improvement in nutrition), the less the increase in dental caries. At 6 years of age the same relation was found to exist, but not at 7 years, when the position is complicated by the shedding of so many of the deciduous teeth.

It may be concluded that even in children who have not received any special dietary treatment an improvement in general nutrition, as gauged by the weight and height index, is found in conjunction with increased resistance of the deciduous teeth to dental decay. Thus yet another factor in the tangled story seems to be established and an obvious practical step indicated in prevention and control. The individual child, though deprived of sunshine and inadequately nourished, may still turn up with a good set of teeth to disconcert the investigator; but such an event is a rarity and should not influence those who aspire to prevent or control dental caries in the young.

DARK-ADAPTATION TESTS FOR VITAMIN A DEFICIENCY

Since our last reference[3] to night-blindness and vitamin A further reports have appeared of attempts to use modifications of the biophotometer for the determination of the vitamin A intake of human beings. Isaacs and his colleagues[4] use an adaptometer made according to the specifications of Hecht.[5] They stress the importance of having control subjects in their experiments and of statistical analysis of results to prevent the drawing of unsound conclusions. In their own work they were unable to produce recognizable vitamin A deficiency by giving large doses of liquid petrolatum (5 c.cm. per kilogramme body weight) daily for periods up to 131 days in twenty-eight normal young adults. During this time twenty-nine untreated normal young adults were also under observation. Moreover, a diet containing only 74 U.S.P. units of vitamin A daily failed to produce definite measurable visual evidence or subjective signs of deficiency in three subjects in forty-three to forty-nine days. Nor when they

[5] *J. optic. Soc. America*, 1938, **28**, 269.

were given massive daily doses of 300,000 U.S.P. units of vitamin A with 2,700 units of vitamin D in the form of a vitamin concentrate did they show any improvement. There was some trend towards increased dark-threshold levels between September and December in both the experimental and control groups. These workers conclude that the standard of vitamin A intake on which subjects are judged to be deficient is questionable, and that the procedures being used for measurement are probably recording something other than vitamin A deficiency. Blanchard and Harper[6] used a regenometer which also conformed to the specifications laid down by Hecht. It breaks down the visual purple of the retinal rods by a bright light and then measures the speed with which this rod pigment is regenerated. It measures the length of time required by the subject to perceive light of a fixed intensity instead of the intensity that can be perceived at a given moment. Ten students of 19 to 24 years of age were fed on diets low in vitamin A (300 to 550 U.S.P. units per day). At first the times required to see the test light varied from one to three minutes. As the time of the low vitamin intake went on, the time needed to see the test light rose to four to twenty-four minutes, the increase being gradual at first but more rapid later. On being given extra vitamin A improvement was detected in one to three hours, and a return to the normal range was obtained within two to ten days in six subjects, and in rather longer times in three more. The dose required for this was 1,500 to 3,600 U.S.P. units a day. Massive doses up to 250,000 U.S.P. units were not proportionately more effective than the smaller ones. A dose of 500 units caused some improvement but did not restore the subject to normal. Experiments with the biophotometer were made on the same subjects at the time when the regenometer recorded the longest adaptation times. Most of the subjects were found to be within the normal range by the biophotometer, and the workers conclude that the regenometer has a greater sensitivity in the detection of early stages of vitamin A deficiency. No clinical symptoms of vitamin A deficiency were observed during the course of the experiments.

ACUTE PULMONARY OEDEMA

Acute pulmonary oedema is considered by most clinicians to be a manifestation of failure of the left ventricle. The signs and symptoms are usually explained by the inability of the left ventricle to expel the blood delivered by the right ventricle, with consequent congestion in the pulmonary vascular bed. This explanation seems straightforward and reasonable; it provides a superficial explanation of the association of acute pulmonary oedema with disease or strain of the left ventricle, of the clinical picture, and of the benefit which results from venesection. Unfortunately, as experimental and clinical observations on pulmonary oedema have accumulated it has become clear that the validity of the "back pressure" or "left ventricular failure" theory can no longer be considered as established. In a recent review of the subject Luisada[7] emphasizes that pulmonary oedema cannot be produced experimentally by overloading the left ventricle or, indeed, by any mechanical procedure which would be expected to produce pulmonary congestion. He suggests that the primary factor is neurogenic, and that it is only when this is present that simple mechanical changes in the cardiovascular system can produce pulmonary oedema. The nature of this neurogenic factor is obscure. Various lesions in the central nervous system have been shown to lead to pulmonary oedema. Reflex stimuli arising in the heart and large vessels and in the hollow viscera may be precipitating factors. This review by Luisada is valuable, not because it clarifies the physiological processes involved in pulmonary oedema, but because it stresses certain inadequacies in the generally accepted theory that the disease is due to left ventricular failure. Another type of pulmonary oedema which is of more than topical interest is that produced by poison gas, and in the case of phosgene it has been stressed repeatedly[8] that vagal stimulation may be in part, at least, responsible for the pulmonary oedema. Only brief mention of this is made by Luisada, and he concludes that, although the inhalation of irritating gases may cause pulmonary oedema by direct damage to the capillaries, there are additional factors, nervous in origin, which are of importance.

NEUTRONS IN THE TREATMENT OF CANCER

The biological effects of fast neutrons have now been sufficiently investigated to permit their use in the treatment of cancer. Stone, Lawrence, and Aebersold[9] have had the use one day each week of a cyclotron, in which a beryllium target is bombarded by deuterons with energies of 8 million volts, producing a beam of neutrons with an intensity of 3 *n*/min. at a distance of 70 cm. from the target. The "*n*" unit is an arbitrary measurement of the intensity of a neutron beam, being that quantity of neutrons which produces the same amount of ionization in the thimble chamber of a Victoreen dosimeter as would 1 *r* of *x* rays. Thus the doses of neutrons and of *x* or gamma rays to effect the same biological change may be compared. As pointed out in a recent paper by Gray, Mottram, Read, and Spear,[10] neutron ionization is usually more efficient, even when the fullest allowance has been made for the uncertainties of neutron dosimetry. The ratio of the gamma-ray dose in *r* to the neutron dose in *n* for the same biological effect is usually of the order of 4, while in one case—the lethal effect on bean roots—it is as high as 11. Gray, taking into account the fact that neutron radiation produces in tissue seven times as much ionization as in an equal mass of air, whereas the absorption of gamma-ray energy is very nearly the same per unit mass of air and of tissue, has defined a neutron unit based on the increment of energy in unit volume of tissue, and this fortunately appears to be roughly equal to the arbitrary *n* unit of Lawrence and Aebersold. Gray and Spear find that there is a qualitative difference between gamma rays and neutrons in their inhibitory effect on mitosis in tissue culture, as well as the quantitative difference which alone has been found in previous experiments. As is well known, there is a threshold of intensity and dose below which gamma rays have no observable effect, but for neutrons this appears to be zero. Stone also describes a small qualitative difference in the erythema produced by neutrons: it appeared earlier and had more dry flaking of the skin than the corresponding *x*-ray erythema. The average single dose given on a 10 by 10 cm. field was 150 to 200 *n*, which had the same effect as 900 *r* of 200 kV *x* rays. Twenty-four patients with advanced lesions were treated in the preliminary experiment, and in every case there was some decrease in the size of both the primary growth and the metastases, in spite of the fact that they were single-dose treatments, not fractionated and not approaching the skin tolerance. Perhaps the most promising observation was that the metastases in the cervical glands responded better than the primary growth, although, in the absence of any measurement of the percentage depth dose, it is

difficult to assess its significance. Stone now has a new cyclotron of double the power to be used largely for clinical purposes, so that he is able to give fractionated treatment, each dose being 50 *n* at the rate of 5 *n*/min. He appears to have solved the problems of collimating neutron beams and of protection of the personnel, and his further results will be awaited with interest.

ECONOMY OF DRUGS IN WARTIME

Our *Supplement* this week reproduces substantially in full a memorandum, drawn up by the Therapeutic Requirements Committee of the Medical Research Council, on economy in the use of drugs in wartime. For the convenience of readers we have regrouped the complete list of drugs into the four categories adopted by the committee instead of printing them all in alphabetical order as one very long table with key letters. The committee, at the end of a prefatory note, makes it clear that this list is primarily intended to secure the wisest economy in drugs for human and veterinary use in this country and that other considerations may affect the importation or manufacture of drugs for the export trade. The committee also indicates the reasons underlying its classification of drugs and puts forward a number of points for the information and guidance of medical and veterinary practitioners when prescribing under the conditions of to-day. Economy in the use of a drug may be necessary in wartime because the drug is imported or because its manufacture at home diverts materials and skill from other essential services. An appendix (which we do not reproduce) gives a list of the drugs whose production the committee recommends should be encouraged either in the United Kingdom or in the British Empire. The pamphlet is published as M.R.C. War Memorandum No. 3 by H.M. Stationery Office, price 3d.

IMPETIGO

Impetigo contagiosa is perhaps the commonest of skin diseases. But although much work has been done upon it, both clinically and bacteriologically, since it was originally described and differentiated by Tilbury Fox nearly eighty years ago, the question of its aetiology is still open to debate. Soon after the beginning of the present century Sabouraud appeared to have proved that impetigo was always caused by the streptococcus. That the staphylococcus was often grown from impetiginous lesions was thought to be accounted for by the fact that staphylococci tended to swamp streptococci when grown under aerobic conditions; the staphylococci were considered to be secondary contaminations. Bullous impetigo was well known clinically, but the bullae were regarded merely as overgrown vesicles, and vesicular impetigo with typical "stuck-on" crusts was known to be of streptococcal origin. Of late years, however, the position has changed. Pemphigus neonatorum, which has always been recognized as closely related to bullous impetigo, and in point of fact can be considered as an extensive and virulent form of that eruption, is now generally acknowledged to be the result of a staphylococcal infection. A number of observers have also shown that bullous impetigo is always of staphylococcal origin. It now appears, therefore, that there are two types of impetigo which can usually be differentiated clinically, though the two types are sometimes mixed. At Jadassohn's clinic all the workers on this disease used to record their opinions about the type of each case, and after a while there was almost always unanimous agreement on whether a case was streptococcal, staphylococcal, or mixed. Epstein,[1] who originally worked in Jadassohn's clinic but is now in America, has lately done much to support the theory that there are two types of impetigo, which may become mixed in the same patient. He studied the staphylococci obtainable both from cases clinically characteristic of staphylococcal impetigo and from those of streptococcal impetigo, in which staphylococci could only be looked on as secondary contaminations. Epstein found that in the former every case studied yielded the same type of staphylococcus; in the cases which were clinically streptococcal numerous staphylococci were isolated.

The great difficulty in studying the bacteriology of the skin is that normally all types of micro-organisms are constantly present on it. With suitable methods of cultivation a great variety of cocci, fungi, and yeasts can be grown from the skin. Nevertheless the constant appearance of one type of staphylococcus in clinically distinguishable cases strongly suggests that this type is the causal organism. Epstein has also experimentally produced bullous staphylococcal impetigo by inoculation with a pure culture of *Staphylococcus aureus* obtained from lesions of bullous impetigo. Another point in favour of staphylococcal impetigo as a clinical entity is the fact that staphylococcal and streptococcal impetigo vary in frequency according to age groups, the former being relatively commoner in adults. It is also found oftener in some localities than others.

A TRIBUTE FROM NEW ZEALAND

Many kind things about our Centennial number have been said by readers at home and abroad. We take particular pleasure in quoting as follows from an editorial in the *New Zealand Medical Journal* for December, 1940:

"The official Journal of the parent body celebrated its centenary on October 5, 1940. Thus the birthday number of the most widely circulated and most influential medical periodical in the world was constructed and published in London after weeks of intensive air raids. To this creative effort, and indeed to the sustained excellence of the *British Medical Journal* under extreme duress, we do homage. Perhaps we in New Zealand, who can only speculate as to what the future has in store, will see some special significance in this particular number from Tavistock Square, which deviates not one iota from the traditional dignity and excellence of its forerunners and which betrays not by so much as a misplaced comma the magnitude of the difficulties which must have attended its birth. If men of great courage and high ideals can successfully prosecute the dissemination of professional knowledge under conditions of total war, which we can only dimly comprehend, then the ultimate future of our ideals and of our profession must be secure. We are told there is an intellectual black-out in Europe at present; but there has been no black-out of the *British Medical Journal* or, indeed, of any other of the well-known medical journals of the United Kingdom on which we rely so much."

[1] *Arch. Derm. Syph.*, Chicago, 1940, 42, 840.

Mr. Gilbert H. Carr, honorary secretary of the American Committee for Air Raid Relief and of the Advisory Committee of the British War Relief Society of America, has been appointed Director-General of the American Ambulance, Great Britain.

FURTHER CASES OF CRUSH INJURY

COLLECTED BY THE MEDICAL RESEARCH COUNCIL SUBCOMMITTEE ON TRAUMATIC OEDEMA

With the kind permission of the physicians and surgeons concerned abstracts are appended of 11 case reports sent to the Medical Research Council. All these patients were pinned under debris for a period between three and twenty-six hours.

Group A: Fatal Cases.—Cases I to VI proved fatal between the fifth and tenth days: they ran a course similar to that of the cases details of which are given in the papers in this issue contributed by Bywaters and Beall (p. 427) and Mayon-White and Solandt (p. 433), with hypertension, blood-stained urine, oliguria, and oedema of the crushed limbs. These had plasma and serum transfusions only. Cases IV and V showed albuminuria only. *Post-mortem* examination revealed what appeared to be blood casts in the renal tubules in 4 cases.

Group B: Cases with Recovery.—Blood was found in the urine of Cases IX, X, and XI, and in the cases without haematuria (VII, VIII, and IX) the urinary output rose to normal on the fifth or sixth day. Case IX had no intravenous therapy, but the blood pressure rose to 176/110 mm. Hg. Although in this second group of cases the degree of swelling and the duration of crush differ little from those of Cases I to VI, yet the patients recovered, except for local tissue death.

Case I

A man aged 20 was pinned down by debris on the left lower leg for ten hours.

Examination.—Hb 150%. P. 135. B.P. 110/70. 1,120 c.cm. plasma given.

2nd Day.—Hb 130%. P. 110. B.P. 130/88. Intake by mouth 1 litre. Urine 650 c.cm.

3rd Day.—Drowsy. L. leg tense and swollen with pitting oedema. Pulse palpable; better on injured side. Anaesthesia of left leg. Fracture of tibia (radiograph). Slight vomiting. B.P. 155/100. Hb 120. Blood urea 188. Blood potassium 26 mg.; plasma chloride 480 mg.; blood phosphate 7.7 mg. per 100 c.cm. Urine (catheter) 205 c.cm., smoky, with pigment-cast sediment. E.C.G. showed slurring of QRS.

4th Day.—B.P. 150/100. Hb 100. Vomiting, drowsy, hiccup. Urine 100 c.cm., clear yellow. Microscopically: rare pigment cast. Intake 1,350 c.cm. 1 litre of 5% glucose given intravenously.

5th Day.—B.P. 160/100. Hb 98%. Vomiting, drowsy, slightly disorientated. Intake 990 c.cm. Urine 250 c.cm., clear. No sediment.

6th Day.—Urine 490 c.cm. A few casts.

7th Day.—Died very suddenly with marked stertor and irregular pulse. Observations on swelling of the leg were made and daily biochemical analyses of blood and urine were performed. These are included in the fuller account of this patient published in this issue at p. 432.

Necropsy (Dr. Miles).—Gross necrosis of muscles with fracture of tibia. Collapse of right lower lobes of lung. Kidneys pale. Microscopically: Tubular degeneration and pigment casts in the collecting tubules.

Case II

A youth aged 17 was pinned down by three dead bodies under timber and rubble for fourteen hours.

Examination.—Drowsy. P. 96, volume good. Abrasions on arms and whealing on right foot, leg, and lumbar region. Impaired movement of right chest.

3 Hours after Admission.—B.P. 100/70.

7 Hours after Admission.—Condition poor. B.P. 80/60. P. very poor (120). Some slight vomiting. Was given oxygen, morphine, coramine, 200 c.cm. of twice-normal reconstituted dried serum (M.R.C.), and 5 c.cm. desoxycorticosterone.

2nd Day (12 Hours after Admission).—120 120 c.cm. dark brown urine obtained by catheter; contained large number of blood casts. P. 104. B.P. 100 80. Was given plasma, 1,680 c.cm., 560 c.cm. 2½% glucose. B.P. rose to 140/90. Still vomiting; some brawny oedema of right lower abdominal wall. Hb 95%. Blood urea 101 mg./100 c.cm. Later—4.3% sodium sulphate, 560 c.cm., and 5% glucose, 1,180 c.cm. given intravenously. Total urine for the day 170 c.cm. Condition fair but restless.

3rd Day.—Urine 60 c.cm., dark, and contained a few casts. P. 104. B.P. 150/100. Vomiting. 900 c.cm. Sweating. Drowsy, restless, oedema of right foot. Intake 2,110 c.cm. by mouth. 5 c.cm. desoxycorticosterone and 5 minims adrenaline given. Blood urea 45 mg. 100 c.cm. Hb 98%.

4th Day.—Patient more drowsy. Continual vomiting. Oedema of right leg. P. 112. B.P. 175 85. Blood urea 69 mg. 100 c.cm. Urine 45 c.cm. A few casts still present. Sodium sulphate, 840 c.cm., and glucose saline, 1,680 c.cm. In spite of this, condition deteriorated. He became flushed, breathing stertorous, and moist sounds were heard all over the chest. P. 120. B.P. 180 80. *Patient died on 5th day.*

Necropsy.—Lungs: fibrinous exudate over left lung and congestion. Kidney: cortex pale. Spleen: congested. Microscopically: pigment casts in the collecting tubules.

Case III

A man aged 28 was pinned under debris by the right leg for six hours.

Examination showed a few grazes only, no fracture (radiograph).

2nd Day.—Marked swelling of upper thigh. Plasma, 560 c.cm. preceded by saline, 1 litre, given intravenously. 1 hour after completion of plasma transfusion, 120 c.cm. of dark smoky urine passed.

3rd Day.—A small amount of urine passed.

4th Day.—A small amount of urine passed.

5th Day.—Began to sweat. A small amount of urine (a few ounces) was passed daily for this and the next four days, containing albumin, blood, and casts. The pulse varied from 55 to 80. B.P. rose to 150 100. Despite intravenous 50% glucose and mersalyl he died on the *10th day.*

Necropsy (Dr. Powys): 24 hours after death.—Slight right-sided dilatation of heart with petechiae of pericardial surface. Massive collapse of both upper lobes of lungs with oedema elsewhere. Liver: congested, cloudy swelling. Kidneys: cloudy swelling and mottled cortex. Microscopically (Dr. Bryson): blood casts in tubules.

Case IV

A girl aged 15 was buried under debris for thirteen hours. She complained of numbness of right leg and pain in right hip.

Examination: Large raised wheal over right buttock and across abdomen. Tender over right hip. Radiograph showed linear fracture of right pelvis. Pulse 124. B.P. 98/70. T. 100°. Has passed urine. Anaesthesia of right thigh, right leg, and right foot. Very thirsty.

10 Hours Later.—Restless. Mentally very alert. Hb 120%. Pallid, cyanosed, and vomiting. B.P. unobtainable. Plasma given intravenously. Urine 180 c.cm., obtained by catheter, containing albumin; sp. gr. 1016. Complained later of abdominal pain with rigidity in right iliac fossa. Blood drip started.

2nd Day.—B.P. 90 70. Less vomiting. Less abdominal pain. Urine 360 c.cm., nothing abnormal detected; sp. gr. 1018.

3rd Day.—Still very thirsty and mentally alert. Some return of sensation in upper right leg.

4th Day.—Tense swelling of upper right thigh. B.P. 100/70. Slight vomiting. Intake 1,140 c.cm. by mouth. Urine 90 c.cm., containing small amount of protein, moderate number R.B.C., and nothing else abnormal except a few bacilli. Blood urea 228 mg./100 c.cm.

5th Day.—Tense oedema of right thigh, right leg. Vomiting, hiccup. Cystoscopy showed small amount of blood at base of bladder. Blood urea 360 mg./100 c.cm. Clotting times done. 200 c.cm. 50% sucrose given, and later intravenous saline.

6th Day.—Condition worse. Mentally still very alert. Pulse irregular. B.P. not obtainable. Hiccup, vomiting. Hb 90%. Blood urea 398 mg./100 c.cm.

7th Day.—Patient died in coma.

Necropsy.—Lungs: basal collapse. Haematoma in buttocks and near sciatic nerve. The left kidney showed yellow spots all over it and on the cut surface. Bladder showed oedema and a little fluid blood. Microscopically (Dr. Pragel): pigmented casts in collecting tubules and some hyaline materials in Bowman's capsule and convoluted tubules in the lungs. The lungs showed early bronchopneumonia and small areas of haemorrhage with a few capillary hyaline thromboses.

Case V

A man aged 35 was buried under debris with legs between planks for three to four hours.

Examination.—Swelling of right forearm, both thighs, and left calf, with a few abrasions and considerable whealing. Tenderness over pubis, with fracture of pubis (radiograph) but no displacement. P. 102. B.P. 102/70. Hb 150%. R.B.C. 7,200,000. Blood N.P.N. 76 mg./100 c.cm. Urine (by catheter) 150 c.cm., containing heavy albumin deposit. Exploratory laparotomy was done (? laceration of bladder). Following this a further 480 c.cm. of urine was obtained. B.P. 124/94. Total fluid intake for the day, 3.6 litres. Slight vomiting.

2nd Day.—Intake 720 c.cm. Vomiting 420 c.cm. Urine 390 c.cm. Hb 136%. R.B.C. 6,200,000. N.P.N. 120 mg./100 c.cm.

3rd Day.—Pulse 76. B.P. 140/104. Intake 1,320 c.cm. Vomiting 180 c.cm. Urine 450 c.cm. Hb 119%. R.B.C. 6,200,000. N.P.N. 144 mg./100 c.cm.

4th Day.—N.P.N. 168 mg./100 c.cm.

5th Day.—Hb 108%. Faint trace of albumin in urine.

6th Day.—Temperature rose, due to haemolytic streptococcal infection from left leg.

7th Day.—Died. Septicaemia.

Necropsy.—No visceral injury in abdomen or pelvis. Kidneys large (320 grammes), blurred definition of kidney markings. Petechiae in pleura and on heart surface. No microscopical examination made.

Case VI

A woman aged 27 was buried under debris (?) hours. On admission she passed a fair quantity of blood-stained urine.

Examination (2nd Day).—Cold, pulseless, and shocked. 5 pints plasma in 2½ hours raised B.P. to 110/70 and P. to 120. There was slight external bruising of chest and flanks.

3rd Day.—Started to vomit. No urine for 24 hours; 225 c.cm. blood-stained urine by catheter. 4 pints saline given.

4th Day.—Blood urea 164 mg./100 c.cm.

7th Day.—540 c.cm. bloody urine passed, with clots. Caffeine and sodium salicylate grains 7 given subcutaneously.

8th Day.—Bloody urine again, with clots. Patient perfectly rational.

9th Day.—11.30 a.m., patient suddenly died "for no apparent reason."

Necropsy.—Macroscopically: cystitis only. Microscopically (Prof. G. R. Cameron): Lung showed pulmonary oedema. Liver and spleen normal. Kidney showed finely granular exudate in Bowman's capsule and convoluted and collecting tubules. Blood casts and free red cells in the lumen. Focal haemorrhages interstitially. Extensive subpelvic extravasation of blood.

Case VII

A man aged 34 was crushed beneath debris, with pressure on both lower limbs, for twenty-two hours.

Examination.—On admission cheerful; no shock; erythema on legs, with numbness and difficulty in moving them. P. 120. R. 18. T. 100°.

2nd Day.—P. 100. Intake 3,510 c.cm. by mouth. Vomiting, 2,100 c.cm. Urine 300 c.cm.

3rd Day.—Abdominal rigidity. Intake by mouth 60 c.cm.; by vein, plasma 560 c.cm., saline 1,120 c.cm., 4% dextrose 1,120 c.cm. Vomiting, 750 c.cm. Urine 420 c.cm.

4th Day.—Intake by mouth 1,920 c.cm. By vein the same as previous day. Vomiting, 930 c.cm. Urine 420 c.cm. P. now 90. Both legs swelling rapidly and becoming oedematous.

5th Day.—Intake by mouth 1,650 c.cm.; by vein 600 c.cm. No vomiting. Urine 2,190 c.cm. P. now 80.

6th Day.—Urine over 660 c.cm. Evacuated to country.

Examined at base hospital on the sixth day. Anaesthesia and oedema of the foot, with skin sloughs. All pulses palpable. Extremely excitable. B.P. 120/70. Urine sp. gr. 1010 Guaiac test negative. No albumin. Volume about 2 litres daily.

10th Day.—Blood urea 192 mg./100 c.cm. Hb 85%. B.P. 135/88.

13th Day.—Blood urea 84 mg./100 c.cm. Urea clearance 50–60%. B.P. 126/84.

14th Day.—Blood urea 43 mg., plasma chloride 538 mg. per 100 c.cm. B.P. 126/80.

16th Day.—B.P. 126/84. Urine normal.

21st Day.—Blood urea 60 mg./100 c.cm. Urea clearance 45–55%. Slough separating over right outer shin.

25th Day.—Blood urea 30 mg./100 c.cm. Granular and cellular casts in urine in centrifuged deposit. Slough separated —tendons exposed.

3 Months.—Urea clearance 55–68%. Blood urea 30 mg./100 c.cm.

4 Months.—Apparently recovered except for slowly healing ulcer on right outer shin extending down to bone and tendons. Feels well, and ambulatory with leg in plaste B.P. 110/70. Blood urea 28 mg./100 c.cm. Urea clearan 69–71%. Urine sp. gr. 1012. Nothing abnormal.

Result.—Recovered.

Case VIII

A woman aged 28 was trapped under debris for twenty- hours. She complained of numbness and inability to use th left arm and left leg.

Examination.—"Shocked," with shallow gasping respir tion. Subnormal temperature. P. 124. The left chest w flattened and showed poor air entry but no fractured rib Apex beat not displaced. The left leg showed oedema an pressure blisters. There was numbness on the left side of th body. Blisters also on right buttock and left shoulder.

2nd Day.—Hb 104%; T. 100.6°; P. 140. Intravenou plasma 150 c.cm. was given, leading to rigor, followed b 2,400 c.cm. dextrose (4%) saline. Hb fell to 90%. P. 11(Urine 300–350 c.cm.

3rd Day.—Fluids by mouth, 3 litres. Urine output 300–35(c.cm.

4th Day.—Fluids by mouth, 3 litres. Urine, 960 c.cm.

5th Day.—Fluids by mouth, 3 litres. Urine, 1,530 c.cm The left thigh extremely oedematous; a large sloughing are on right buttock, which in the next few weeks separated t expose the gluteus maximus.

10th Day.—Sulphapyridine and blood transfusion given.

5th Week.—Granular and hyaline casts found in urine.

Result.—Recovered.

Case IX

A man aged 31 was buried under debris compressing both legs from below the knees for seventeen hours.

Examination.—Condition good. B.P. 110. Legs painful, with three small abrasions. Loss of touch, impairment of pain sensation, and some loss of muscle movements in both legs below the knee. Urine 390 c.cm., blood-stained. Intake by mouth ? 1,320 c.cm. Pulse rose from 68 on admission to 120 five hours later.

2nd Day.—B.P. 176/110. P. 110. Intake by mouth 2,790 c.cm. Urine 150 c.cm., blood-stained, at 4 a.m. 360 c.cm. clear urine subsequently.

3rd Day.—Now considerable swelling of legs. Intake over the next few days by mouth ranged from 1,260 to 2,670 c.cm. Urine output 720 c.cm., 750 c.cm., 600 c.cm. on succeeding days, rising abruptly to 1,740 on the eighth day.

16th Day.—Still gross oedema; skin glossy, flushed, and hot, with pitting oedema.

4th Week.—Oedema now almost disappeared.

Result.—Recovery.

Case X

A girl aged 17 was buried under debris for thirteen hours.

Examination.—Drowsy: abrasions to face; fracture of forearm; burns both hands and feet. B.P. 110/80.

9 Hours Later.—Restless. B.P. falling (90/80 and lower). Intravenous plasma and proseptasine given.

2nd Day.—B.P. 115/100. Swelling of right knee and of face. Over 360 c.cm. urine containing albumin; sp. gr. 1024.

3rd Day.—Left foot cold, blue, and mottled. Firm oedema below knee. No pulsation felt at ankle. Bruising of left thigh. Under gas-and-oxygen, multiple incisions, evacuating much fluid, made into deep fascia.

4th Day.—Condition poor; vomiting. 5% dextrose and heparin given intravenously. Foreign body removed from left eye.

5th Day.—Gangrene left toe.

6th Day.—Condition better. No more vomiting. Oedema less.

7th Day.—Transferred.

At Leavesden Hospital the left leg became less swollen but still showed anaesthesia. Amputation through the tibia was done (for gangrene). The muscles had undergone avascular necrosis. Three months after accident general condition good.

Case XI

A youth aged 17 was trapped by legs under debris for twelve hours.

Examination (36 hours after injury).—Restless. B.P. 120/74. P. 88. Pitting oedema left and right legs. Right foot blue and cold, and dorsalis pedis not pulsating. Macroscopic haematuria, which diminished during the next four days. 8.5 grammes of sulphapyridine on first, second, and third days. 2 pints Group O blood on second day.

5th Day.—Circulation returned to leg, which showed blebs. No haematuria.

8th Day.—Blood urea 40 mg./100 c.cm. Several hyaline and granular casts noticed.

12th Day.—Superficial gangrene of leg. Considerable number of casts.

25th Day.—Hb 60%. Osteomyelitis and osteoperiostitis of tibia and fibula.

47th Day.—Muscle slough separating.

Result.—Recovery.

It is to be hoped that in future cases particular attention will be paid to: (1) Presence of anaesthesia or whealing. (2) Oedema—daily extent and progression (circumference measurements). (3) Pulse in the limbs, and, if possible, oscillometric readings. (4) Blood pressure, initial and daily readings. (5) Initial haemoglobin measurements and biochemistry of blood (serum for potassium and urea). (6) Urine, daily from time of entry, quantity, colour, and examination for blood, albumin, and casts.

The Subcommittee on Traumatic Oedema of the Medical Research Council desires to thank the following for their kindness and co-operation: Mr. Romanis (Case I), Miss Margaret Louden (Case II), the Chief Medical Officer of the L.C.C. (Case III), Dr. Avery Jones and Dr. Abdullah (Cases IV and X), Dr. Pochin and Dr. J. Squire (Cases V and IX), Dr. Whittingham (Case VI), Prof. Christie, Mr. Naunton Morgan, and Mr. Hosford (Case VII), Mr. Naunton Morgan (Case VIII), and Dr. Bolton (Case XI).

AWARDS FOR GALLANTRY IN CIVIL DEFENCE

The award of the George Medal to Dr. O. M. Holden, medical officer of health, Croydon, is announced in a *Supplement* to the *London Gazette* dated March 7.

DR. OSCAR MADELEY HOLDEN: "A heavy calibre bomb hit a report centre, completely demolishing it. There were five telephonists in the room at the time, three of whom were killed instantaneously and two ultimately rescued alive. One of the latter was trapped under tons of debris, but was able to communicate with the rescue party personnel. It was seen that she had been severely injured. Dr. Holden, at great personal risk, crawled under the wreckage and proceeded in the most difficult conditions imaginable to administer morphia to her. Owing to the abnormally confined space in which he had to work Dr. Holden was only able to come out by crawling backwards. During the time he was working debris was continually shifting and he was in great danger of being buried under the ruins."

The award of the George Medal to Dr. D. C. Logan, assistant medical officer of health and resident hospital medical officer, Clayponds Emergency Hospital, and to Dr. M. Kamill, house-surgeon, Clayponds Emergency Hospital, is announced in a *Supplement* to the *London Gazette* dated March 14.

DR. DANIEL CRAWFORD LOGAN and DR. MOSTAPHA KAMILL: "A time bomb penetrated the roof of the diphtheria block at the Clayponds Hospital, coming to rest among debris on the floor of the bathroom, without exploding. Dr. Logan and Dr. Kamill, who had experienced the results of previous bombings on the hospital, arranged for the evacuation of the patients. They carried out their duties with coolness and courage, regardless of any danger to themselves, and prevented the possibility of great damage being done to the hospital buildings and to the houses of people adjoining. There is no doubt that by their initiative and devotion to duty Drs. Logan and Kamill saved many lives."

AUSTRALIA

The Australian Red Cross Society

The Charles Mackay Oration was delivered recently at the Institute of Anatomy in Canberra by Dr. J. Newman Morris, C.M.G., whose subject was the origin and growth of voluntary aid to the medical services in time of war. After a sketch of the policy and structure of the Red Cross movement, he dealt with the history of the Australian Red Cross Society, which was founded in 1914 as a branch of the British Red Cross organization, and in 1926 became a national society on its own. Voluntary aid detachments have been a recognized technical reserve of the Australian Army Medical Corps ever since the last war, and the administration is vested in a joint council as in Great Britain. One service of the Australian Red Cross in the present war was specially mentioned by Dr. Morris—namely, the organization of blood transfusion. It was considered necessary to provide an emergency transfusion service among women, who have readily volunteered, and the technical work has been done almost entirely by women doctors. The transfusion service of the Australian Imperial Forces has found this Red Cross emergency service of the greatest value, and it has been worked in association with the Commonwealth Serum Laboratories. The latest contribution of the women has been to give large quantities of blood serum, which is preserved and forwarded over-seas to be used for wounded men of the A.I.F. Other work of the Australian Red Cross has been the maintenance of a Red Cross unit in the Middle East, the provision of sixty-three ambulances for service with the Forces and of six mobile advanced dressing stations, and the establishment of convalescent homes for sick men of the Forces in three States. It is probable that since the oration was published, in November of last year, these provisions have been largely exceeded.

INDIA

The Health of Bombay

The Province of Bombay has a population of close upon twenty millions and a birth rate of 39 per 1,000, which is nearly three times the birth rate of Manchester. The infant mortality rate (152.7 per 1,000 births) in 1939 was the lowest ever recorded in the province. The increase of population is regarded with some disquiet. As the annual report of the Director of Public Health points out, at one time a high birth rate was taken as an index of the prosperity of the country. Evidently, an unhealthy population cannot be expected to have a high birth rate, but at the same time it is not impossible for a prosperous and healthy country to have a comparatively low one. A reasonably low birth rate is far to be preferred, says the Director, to the excessive one of over 50 per 1,000 which is recorded in several districts of the province. The death rate in Bombay (25 per 1,000) is going down, and the decrease applies to almost every one of the common causes of mortality. It is pointed out that the total death rate in recent years has been scarcely affected by any decrease or increase in deaths due to epidemic diseases. It depends mainly upon constitutional rather than accidental causes. The latter have in recent years been brought under control to a great extent, so that it is now unusual for an epidemic to run like wildfire and cause enormous waste of life as formerly. The only diseases for which an increase in the death rate is recorded are plague (a slight increase) and smallpox (a considerable increase, from 0.24 per 1,000 in 1938 to 0.38 in 1939). Although there was a decrease in the number of deaths from tuberculosis, 23,195 persons died from the disease in the year 1939, and the total deaths due to all epidemic diseases do not amount even to one-half of the deaths caused by tuberculosis. It would therefore be unwise to assume that the spread of tuberculosis has been checked, or that the factors causing constitutional diseases—low standard of living being the most prominent—have been removed. The cholera epidemic of 1939 was of a mild nature, and the number of deaths was the lowest since 1932. The annual report bears encouraging witness to the growth of urban and rural sanitation in Bombay and the activity of many health movements, especially maternity and child welfare and school hygiene.

Reports of Societies

WAR INJURIES OF THE SPINE

A meeting of the Section of Surgery of the Royal Society of Medicine was held on March 5, Mr. J. B. HUNTER presiding, at which a discussion took place on "War Injuries of the Spine."

Mr. JULIAN TAYLOR, after some reference to the historical aspects of the subject and his own experiences during the last war, said that the injuries fell into two classes, the larger being what might be called the civil group, in which motor cars or falling masonry were the usual causes; and the smaller, the group of injuries caused by projectiles. The damage to the cord and the effect on the functions of the victim were similar in both classes, and in all cord injuries and in both groups there was a high proportion of neurologically complete interruptions. Interruption of conductivity of the cord might be due to one or more factors. Thus there might be complete severance, physiological interruption due to crushing without section, or what was called spinal concussion or shock. These were instantaneous events, but at the site of crushing there usually occurred some bleeding later, which tended to spread up and down the substance of the cord in more or less cylindrical form, giving place still later to cavities containing clear fluid.

The effect on the conductivity of the cord of all these agencies, except severance, might be transient; part of the immediate effects might be due to temporarily acting conditions, part to permanent. Theoretically, by adding a fraction of the temporary to a fraction of the permanent a complete interruption might be made, and thus it would not be possible to say what chance there was of improvement of a temporarily complete paraplegia. Unfortunately there was no such ground for uncertainty, for it was the experience of Sargent and of Trotter that with early complete paraplegia no return of function was to be seen. The speaker himself had never found evidence of recovery in such cases.

Interruptions of the Spinal Cord

Haemorrhage into the substance of the cord was capable of producing increasing degrees of interruption after an accident. The increase was due at first to continued effusion of blood, and later to the reaction to its presence in the tissues of the cord. A partial lesion might be recognized clinically by persistence below its site of skin sensibility or of motor power or of reflex activity. There was such a thing as the academically incomplete lesion—one which showed during its later history that it was not quite complete, but which gave back no useful function, although some slight return of sensibility might be seen.

Although partial lesions revealed their nature at once or in an early stage, he did not wish to imply that they proceeded to complete recovery either invariably or rapidly. But the fact that a lesion was a partial one indicated that the violence which reached the cord was slight, and thus it might be hoped that useful recovery would occur, although a year or longer might elapse before recovery was established. These partial lesions were obviously the only ones which, from the point of view of the cord, were worth operative or manipulative treatment with the object of relieving pressure. Experience of the present war had suggested that partial lesions were of great rarity in both the groups he had named. Dr. Gordon Holmes in his Goulstonian Lectures in 1915 mentioned 300 cases in only forty-five of which were incomplete lesions found. In less than one-sixth of the projectile cases the question of surgical relief of pressure might be considered, and in the majority even of these it was likely ultimately to be rejected.

Injuries caused by Projectiles

In an incomplete lesion the presence of metallic or bony fragments might cause persistent pressure on the cord, and these should be removed. It was rare for metallic fragments to be held up in the spinal canal, for a projectile which had the energy necessary to penetrate the canal or fracture its walls had usually enough left to carry it out again into other tissues. Another reason for removing metallic fragments, irrespective of the position of the foreign body, was the prevention of infection. As an infected track must pass by the cord or meninges, an infected wound was an obvious source of meningitis. When entrance wounds were suppurating freely, as was usually the case, the rule should be to bring the wound to as clean a state as possible by a superficial drainage operation before removing the foreign body. Meningitis in penetrating wounds of the central nervous system was extremely common in neglected cases, but mortality from it was low. In discussing the treatment of the infected focus Mr. Taylor mentioned the new bactericidal drugs, but stressed his view that these were adjuvants to surgical treatment, though he agreed that sulphapyridine had in certain cases cleared up staphylococcal meningitis when no other treatment, not even by lumbar puncture, had been employed.

In at least five cases out of six, transport, nursing, and management of the bladder were the beginning and end of treatment. The primary needs of the patient with the anaesthetic back were distributed pressure, continual changing of the sites of pressure over bony prominences, and cleanliness of the skin. Whereas water beds and sorbo-rubber mattresses permitted all of these, plaster beds invariably gave rise to bedsores.

Management of the Bladder

Finally, Mr. Julian Taylor dealt with the management of the bladder, the most important duty of the medical attendant. When there was retention of urine, which almost

invariably occurred, there were three methods available: regular catheterization, the tied-in catheter, and suprapubic drainage. Each had its disadvantages. For the patient who might recover his vesical function he recommended regular catheterization, and the same procedure for the patient likely to develop automatic micturition. For the patient who was not going to improve or to develop automatic micturition—for example, one suffering from a cauda equina lesion—he recommended suprapubic cystotomy with lavage of the bladder at low pressure. For the patient who had to travel a long distance in an ambulance a catheter tied in and scrupulously arranged was probably the least harmful expedient.

Types of Fractures

Mr. R. WATSON JONES divided injuries of the spine into three groups: compression fractures of the vertebral bodies, avulsion fractures of the transverse and spinous processes, and penetrating wounds of the spine. Investigations he had pursued in recent weeks showed that the surgeons of the Royal Navy, of the Royal Air Force, and of the Emergency Medical Service were faced to-day, exactly as in days of peace, with a very large number of uncomplicated fractures and a very small number of spinal cord injuries. He mentioned a form of fracture almost unknown in this country until twelve months ago. It was called "shoveller's fracture," in which the spinous process was torn off the vertebra by violent contraction of the rhomboid muscles at the moment that a labourer drove his shovel into wet clay or flung the laden shovel into the air. Its recent frequency was among those engaged in excavating shelters, digging trenches, or clearing debris.

Of vertebral body fractures the simple wedge compression was by far the most common. It was likely to be sustained by the dock labourer who fell into the hold of a ship, the window cleaner who fell from his ladder, or the steel erector who fell from scaffolding. In another type of fracture in which the vertebral body was comminuted the injury was usually due to the fall of a weight across the shoulders, as in the case of a miner trapped by a fall of roof. Fracture-dislocation, most often seen in car accidents, was, like comminution, due to acute angulation, but with a traversing momentum which carried the upper segment of the spine forwards so that the spinal cord was often injured. In the Royal Navy the most frequent war injury of the spine was a simple wedge compression of one or more lumbar vertebrae, with or without a fracture of the os calcis. It was often caused by jumping from the deck of a torpedoed ship or by the explosion of a mine below the vessel. In the treatment of these lumbar fractures two points were important: (1) the compression could be completely reduced by hyperextension of the spine by the two-table method, but the limit of hyperextension must be reached; (2) the fully extended position must be maintained by an adequate plaster jacket for not less than three months.

Fractures sustained by Airmen

In the Royal Air Force fractures of the lumbar region might again be sustained as a result of parachute or crash landings, but the commonest fracture was one in the upper half of the dorsal region of the spine. The reason for the localization lay in the fact that the pilot was partly fixed to the back of his seat by a special harness which prevented forward movement of the shoulders, so that if a fighter aircraft crashed the pilot could not double up in the ordinary way at lumbo-dorsal level, but the momentum still tended to carry his head forward, so that the site of angulation of the spine was the upper dorsal region.

The reduction of these high dorsal fractures was very difficult, but for that very reason perfect replacement was relatively unimportant. As the injured vertebra lay in the middle of one of the arms of leverage it was in a relatively immobile segment of the spine, and in such cases perfect function was compatible with definite compression of the vertebra. In treatment the spine was extended as much as possible, and a wing of plaster was added across the front of each shoulder to maintain extension of the upper dorsal region, but not to include the cervical region and head. Immediately after reduction of the fracture hyperextension exercise was undertaken. With such treatment it had been unnecessary to immobilize the spine for more than two months.

Prognosis in the lumbar region was relatively good. More than half the cases of fracture-dislocation at this level with paraplegia made a complete recovery. In the dorsal region, on the other hand, the spinal cord almost completely filled the spinal canal, and recovery from paraplegia was not observed in more than 15 or 20% of cases.

Spinal Injuries in Air-raid Casualties

Mr. Watson Jones went on to say that his inquiries showed that surgeons in the Emergency Medical Service who were treating air-raid casualties had to deal with only a small number of spinal injuries. No doubt the mass of masonry which fell on air-raid victims if sufficient to fracture the spine was also sufficient to kill. The few cases that had occurred had been in air-raid shelters, the roof of which had crashed down on to the shoulders of those within. The type of injury sustained was a comminuted fracture or fracture-dislocation of the cervical region.

In the treatment of cervical fracture-dislocations he emphasized the value of skeletal traction from the skull. This was the safest method of reduction and, moreover, the best method of preventing redisplacement. Skull traction relieved pressure on the cervical cord because it not only reduced the bone displacement but by maintaining a distracting force on the intervertebral spaces it encouraged replacement of retropulsed intervertebral disk material.

All the injuries so far discussed were the flexion variety of fracture or fracture-dislocation, and in conclusion Mr. Watson Jones mentioned the rarer hyperextension injuries, as instanced in a sailor who fell on to the deck of a destroyer and sustained violent hyperextension of the spine, with a traumatic spondylolisthesis, so that all the lumbar vertebrae were dislocated forwards on the sacrum. That particular case when he saw it was several months old and it was impossible to attempt reduction, but he believed that the method of reduction he had described for congenital spondylolisthesis would have been effective if applied at an early date. In this method the patient lay face upwards with head and shoulders supported on a table, the hips flexed to the right angle, and vertical traction was applied to the thighs so that the lumbar curve was flattened and the pelvis pulled forwards. Even in congenital spondylolisthesis improvement of position was possible, and in a traumatic case perfect reduction should be obtained.

Technique of the Plaster Jacket

Mr. K. I. NISSEN said that the experience at the Orthopaedic Centre, where in most of the cases received the injuries were at least a fortnight old, was that every plaster jacket had to be removed either immediately or within the first week, on account of faulty technique in its application. In some cases there was incomplete hyperextension and in others incomplete or faulty padding, while a number of plasters were rendered ineffective by excessive trimming above the pubic region and also low down on the sternum. For obtaining hyperextension he had found of great service a sling made of stout canvas about 4 in. wide with padding of 1,4-in. felt, but with the padding completely removed over the front part of the sternum and replaced by some soft materials, such as chamois leather. The sling was used to take the strain off the arms, multiple injuries of which hindered the application of the plaster jacket. He stressed the need for carrying out suprapubic drainage high rather than low in the abdomen. If such drainage were attempted it should be, particularly in a cauda equina lesion, 1½ in. above the pubic crest. He added that the amount of reduction obtained in the cases of spinal fracture which had come to the centre had been most disappointing. If a week had elapsed after the injury, every day diminished the chance of getting a satisfactory reduction, and after two or three weeks the possibility had practically disappeared. The plaster jacket then served the purpose of splintage and not its primary purpose of facilitating complete reduction.

reference was also made in an annotation in the *Journal* (February 22, p. 284), it becomes evident that an embolism may reach the brain from a pelvic or femoral site without passing through the pulmonary circulation. Batson outlined a vertebral system of veins, which have free and valveless communications with those of the pelvis, abdomen, thorax, thoracoabdominal wall, and with the intracranial venous system, and in which there is a frequent reversal of flow. Radio-opaque material injected through the dorsal vein of human cadavers was seen to pass from the pelvic veins to those of the cerebrum without entering the lungs. These results are of the greatest value and serve to clarify a common problem—the mode of blood spread of tumours and inflammatory masses in the absence of secondary deposits in the lungs and of a patent foramen ovale.—I am, etc.,

London, W.1, March 8. J. SHAFAR, M.D., M.R.C.P.

Influence of Heredity on Breast Cancer

SIR,—In your report on the work of the British Empire Cancer Campaign (March 1, p. 329) part of the summary by Mr. J. P. Lockhart-Mummery of the seventeenth annual report of the Campaign is quoted. It reads: ". . . Although it has been known for some time that heredity can influence the incidence of breast cancer in mice, this should not be applied too closely to the problem in man, because the conditions of mating necessary to demonstrate the effect in mice—for example, very close inbreeding, necessitating brother–sister mating—never obtain in any civilized community." It is important for those interested in this problem to realize that when using highly inbred mice to elucidate the factors concerned in the genesis of breast cancer, all that is done is to exaggerate and concentrate certain characters which are normally present but widely dispersed in any mixed stock. Thus factors which would otherwise be lost to view can be studied and influenced at will in many individuals. The mouse is chosen because of its short life span and rapid powers of reproduction, but similar results can be obtained in the rabbit.

No one would deny that the Mendelian laws are as applicable to the human as to the tall and short peas which Mendel used in his original experiments. Yet Mendel could not have formulated the laws if he had not studied an obvious character in a quickly growing plant. Similarly, in the study of breast cancer the use of inbred mice is an invaluable aid to the elucidation of the problem in man. I am prompted to offer this point of view as a reply to the question as to whether it is justifiable for those engaged in cancer research to spend a great deal of time upon experiments in mice. I think it is.—I am, etc.,

University of Leeds, March 7. GEORGIANA M. BONSER.

Muscular Lesions in Somatic Pain

SIR,—I fully agree with Dr. Michael Kelly (March 8, p. 379) in impressing on the general practitioner the great and widespread incidence of muscular lesions and their importance in the treatment of patients complaining of pain the origin of which appears to be obscure. I, too, have stressed this very point in my papers. I also agree that our present conception of the origin of pain will have to be revised in a radical way. But it appears to me that in the first instance we have after R. Leriche (*The Surgery of Pain*, 1939, p. 28) to distinguish between experimental pain as produced in the laboratory by neurologists, and symptomatic or *ut venia verbo*—pathological pain as occurring in diseases. On the other hand, the latest experiments of Sir T. Lewis and collaborators by injection of hypertonic saline into the muscles produced pain which seems to be related to, although not identical with, symptomatic pain, in which doctors are naturally much interested. In my opinion pathological pain is caused by abnormal vasomotor reflexes of parasympathetic (?) or, more likely, of sympathetic origin leading to a "vascular disequilibrium" (Leriche). A close study of the literature on visceral and referred pain seems to point in the direction that pathological pain is very often a sympathetic phenomenon.

If Dr. Kelly and other authors complain that their results regarding muscular lesions are inconsistent and the patients sometimes cannot be cured, it is, in my conviction, due to incorrect diagnosis. An extremely important point is the fact that the diagnosis of muscular lesions can by no means be based only on local tenderness or nodules. This is evident from Dr. Kelly's remark that "these situations" (namely, in the muscles) "are tender in the normal subject." In my experience a muscular lesion may be diagnosed only by the presence of "myalgic spots," the objective signs of which are described in the *British Journal of Physical Medicine* (1938, n.s. **1**, 302, and 1940, **3**, 50). A recent article (*Practitioner*, March, 1941, p. 167) describes the sites of the myalgic spots in all common myalgias of rheumatic, traumatic, and idiopathic origin. In addition it is to be noted that the myalgic spots are as a rule situated in anatomical points—namely, the origin, insertion, along the edge or along the course of a muscle. A second diagnostic point worth mentioning is the fact that the areas of referred pain complained of by patients are not arbitrary but seem to be governed by a law. Taking into consideration the sensory innervation of the skin in relation to spinal nerves—these so-called dermatomes—the pain is referred, at least approximately, to a skin area supplied by one or more spinal nerves which innervate the muscle producing it (*Lancet*, 1940, **2**, 326). In this way the area of pain as mapped out by the patient himself is a reliable guide in localizing the myalgic spots in the individual patient.

If proper care is given to these points and the sites of the muscular lesion are accurately located the results will, I am confident, be gratifying.—I am, etc.,

London, N.W.11, March 13. MICHAEL G. GOOD, M.D.

Analysis of Sulphonamides in Blood

SIR,—The successful therapeutic use of the sulphanilamide drugs frequently necessitates their accurate determination in the body fluids, especially the blood. The Bratton and Marshall method generally used for these analyses gives accurate results with sulphanilamide, slightly low results with sulphapyridine, and lower results with sulphathiazole. The mean analytical recovery from blood to which 5 mg. of sulphathiazole per 100 c.cm. was added is 89.03% if the blood is haemolysed in 1:20 dilution and 94.82% in 1:50 dilution. If, however, haemolysis is prevented by diluting the blood in 0.85% sodium chloride instead of 0.05% saponin or water, the recovery from 1:20 dilutions is increased to 93.88%, and the recovery from 1:50 dilutions to 99.95%. The analyses of blood from patients receiving sulphanilamide, sulphapyridine, or sulphathiazole show that the recovery of sulphanilamide from aqueous and saline filtrates is approximately equal. Saline filtrates of the blood from patients receiving sulphapyridine give a slightly higher recovery than aqueous filtrates. In the case of sulphathiazole saline filtrates give results significantly higher than aqueous filtrates. When aqueous and saline filtrate analyses of sulphathiazole are divided by the appropriate *in vitro* mean recovery values, the 1:20 dilution aqueous and saline filtrate results agree within 7 parts in 470, and the 1:50 aqueous and saline results within 7 parts in 650.

It is evident, therefore, that the complete haemolysis recommended by Marshall and his associates as essential to quantitative recovery makes no appreciable difference in the recovery of sulphanilamide and is to be avoided if precise analysis of sulphapyridine and especially of sulphathiazole is desired. Detailed data upon which these conclusions are based will appear in the *American Journal of Clinical Pathology*.—We are, etc.,

FRANK B. COOPER, M.S.
PAUL GROSS, M.D.
MARION LEWIS.

Pittsburgh, U.S.A., Feb. 11.

Agranulocytosis after Sulphapyridine

SIR,—I should like to report this case of agranulocytosis following only a short course of treatment with sulphapyridine.

A patient of mine, a male aged 26, was taken ill suddenly with severe sore throat, high temperature, and vomiting while on a visit to the country. He was seen by a local doctor. The following day he became worse and he was admitted to a local institution. Sulphapyridine was administered, apparently

with the idea that he was suffering from a severe infection, but there was no improvement in his condition. I went to see him and found that he recently had had a course of sulphapyridine for gonorrhoea. He had treatment for two weeks terminating one week before the onset of his acute present symptoms. Ever since he commenced the treatment he complained of weakness, pain in his limbs, and giddiness. When I saw him, four days after the onset of his acute condition, he looked extremely ill, emaciated, temperature 101°–103° F., with grunting respiration. He complained of sore throat, dysphagia, and weakness. The throat was covered with an extensive slough. I suggested a blood count, which revealed the extremely rare figure of one polymorph per c.mm. Blood transfusion was administered, but unfortunately ten days after the onset of his illness the case proved fatal.

Though this complication is well recognized, I feel that this case should be recorded in order to be on guard even when administering a short course of sulphapyridine.—I am, etc.,

London, E.1, Feb. 28. J. DYWIEN.

Scabies and Subnormal Intelligence

SIR,—I have read with interest the article on the incidence of scabies and its apparent dependence upon subnormal intelligence by Captain Geoffrey Hodgson in your issue of March 1 (p. 316). With experience as a former medical officer in the Navy and subsequently as medical superintendent of a colony of over 400 *male adult* mental defectives I may be permitted to make some observations. No doubt scabies does show greater frequency in those with low intelligence. Where good hygienic conditions are enforceable, as in the Services, infection is generally introduced to the community of men through the same source and by the same type of men as venereal diseases and pediculosis. During the period 1926–36, at all events in the Navy, this source was, both at home and abroad, the inferior types of brothels and shore-side lodging-houses. Only the less intelligent men expose themselves in such places.

From the last sixty new admissions of adult male mental defectives here, all rate-aided and many certified from magistrates' courts, three were found to have scabies. In each case the condition had become resistant to treatment, impervious to improved bodily hygiene, and had ceased to be a source of any discomfort or irritation. The three defectives concerned are fairly typical of the vagrant class and the petty criminal products of our lowest social stratum. It is likely, then, that Captain Hodgson's investigations will prove the relationship he sets forth. As a result, certain subnormal elements will be weeded out from the Forces as a source of impediment to efficiency. A situation will then arise whereby such elements will be returned to their homes to propagate (and their proclivities in this direction are recognized), while those elements from whom propagation should be encouraged are partially or wholly withheld from home facilities.

It would appear desirable, therefore, that the elements so weeded out should be divided into two groups representing two degrees of mental subnormality. Those who are graded "dull" should be retained in special labouring units of the Forces, while those whose intelligence coefficient is so low as to constitute certifiable mental deficiency should be so certified and, if returned to their homes, put under the visiting supervision of their local authorities, or, where possible, admitted to colony segregation. Failing such precautions the proportionate increase of sibs from defective stock would be given a flying start at a time when soundly parented children will be most desirable to the nation in its recovery from war.—I am, etc.,

March 7. J. JOHNSTON MASON,
Medical Superintendent, Brentry Colony, Bristol.

Scabies Treatment in General Practice

SIR,—Captain Geoffrey Hodgson (March 1, p. 316) has shown by intelligence tests what one has always believed to be true—namely, that the patient with low-grade intelligence is the one most likely to get scabies. How does this knowledge affect treatment of scabies in general practice? The patients rarely have bathrooms in their houses, and "a large number of scabietic patients have dirty clothes, dirty skins, and dirty habits." They cannot all be sent to hospital, and because of their low standard of intelligence they can rarely be relied upon to follow instructions for treatment in their own homes. I believe treatment can best be done by the practitioner in his own surgery with "rotenone" solution, as it takes only some five minutes compared with benzyl benzoate treatment, which takes half an hour (*Pharmaceutical Journal*, March 8, p. 79).

In the last three months I have during surgery hours painted with rotenone [which is a constituent of the plant derris] some fifty patients varying in age from 7 months to 75 years, and including three pregnant women. At the first consultation the patient is told to return after having a bath and to bring a clean towel. In front of a fire the patient is painted with a two-inch paint or varnish brush from neck to feet. The towel is used to cover a stool upon which the patient stands. A more important reason, however, for asking the patient to produce a clean towel is that this usually necessitates some clothes washing, which is all to the good. During the painting one has a chance of mentioning the need for frequent bathing, for clean clothing, and for changing of clothing. Possibly, as the one means of relieving the overworked general practitioner, the first-aid posts might be used as centres for treatment under suitable medical direction. I have been agreeably surprised at the good results and the unexpected co-operation of these patients. Many have brought other members of their family, bathed and with clean towel, without making any appointment, and I suggest that the local authorities might print a sheet of instructions which the practitioner could give to his scabietic patients.

I use rotenone 1% B.D.H. or 2% rotenone (sarevan, Evans) depending on how I feel regarding the case. The number of paintings required averages between three and four. There are a few return cases, probably reinfected, who, on instructions, come back immediately itching begins—always bathed and with clean towel—and who do not wait until a large area of the skin is affected. Patients get ready in an adjoining room while surgery is proceeding. For the patients who cannot pay the necessary repeated visits on *consecutive* days—for example, constant overtime munition workers—Evans Sons Lescher and Webb Ltd. made for me in December, 1940, a 2% rotenone ointment. This has been successful in the very few cases so far treated, and I hope to try this out further.—I am, etc.,

Newcastle-upon-Tyne, March 12. S. CALLER.

Medical Woman-power

SIR,—One reads week by week of the difficulty of allocating medical man-power for Service needs, but one looks in vain for mention of medical woman-power. In the last war medical women of my generation served the civil and military hospitals at home and abroad and helped in general practice. When hostilities ceased and men returned many of us married and retired from practice, and have spent the intervening years home-making and rearing families to take their places in the present struggle. Now we offer our services again only to find ourselves unwanted; a recent letter from the Central Medical War Committee informs one that "only a very small demand has been made for women practitioners." Last summer a Local Medical War Committee invited me to accept a post as medical officer to a hospital for evacuated children suffering from minor ailments—surely a suitable job for a medical mother—but the Government medical officer with whom rested the final appointment refused to employ me on account of my female sex.

It is not generally recognized that the practice of medicine being a "reserved occupation," women doctors may not join the women's auxiliary services to the Army, Navy, and Air Force. The only medical work open to women, therefore, is to render assistance in general practice.

To me it seems wrong and foolish that this body of trained and experienced women accustomed to responsibility and comprising, moreover, about one-tenth of the entire medical profession should be side-tracked into the alley labelled "assistant for the duration," where useful work is being done, but work

which calls for these same qualities of physical endurance required by the men and women in the fighting and auxiliary services, and for no other reason than archaic sex prejudice in high places. I do not suggest that women should replace men as battalion medical officers, but there must be many administrative posts which could be filled by women, and certainly the demands of the members of the auxiliary services for women medical officers should be met. One anticipates with interest the report of the Committee on the Allocation of Medical Man-power which Mr. Brown has promised will be published shortly.—I am, etc.,

Tutbury, Staffs, March 3. MARY E. COCHRANE-DYET.

Vision Standards for Grading Recruits

SIR,—I have found the following details of such great service in saving time and worry that I thought other examiners might find them useful:

	R.E.	L.E.
Grade I Standard I: Unaided vision	6/6 6/6 6/9	6/6 6/9 6/6
Grade I Standard II: Unaided vision	6/9 6/9 6/12 6/12 6/12 6/6 6/6 6/6 6/6	6/12 6/9 6/6 6/12 6/9 6 12 6/18 6/24 6/36
Grade I Standard III: Unaided vision less than II but vision can be corrected to at least Standard II. If below 6/60 either eye—specialist. All men not placed in Standard I, II, III, refer to specialist.		
Grade I Standard IV: Unaided vision is less than II but vision cannot be corrected to Standards I or II but can be corrected to	at least 6/12 or 6/36 6/18 6/24 6/36 6/9 6/9 6/9 6/18 6/24 6/36 6/12 6/12 6/12 6/18 6/24 6/36	at least 6/36 6/12 6/6 6/6 6/6 6/18 6/24 6/36 6/9 6/9 6/9 6/18 6/24 6/36 6/12 6/12 6/12 6/12

	R.E.	L.E.
Grade II (a) vision Standard V: Vision can be corrected to at least 6/24 in each eye.	6/18 6/18 6/24 6/24	6/18 6/24 6/18 6/24
Grade II (a) vision Standard VI: Vision in one eye, with or without glasses, is not less than 6 12 and in the other is less than 6/36 with or without glasses, or has been practically lost.	6/6 6/9 6/12 6/60 or less 6/60 or less 6/60 or less 6 60 or less	6/60 or less 6/60 or less 6/60 or less 6/6 6/9 6/12
Grade IV Standard VII	6/18 6/18 6/24 6/24 6/36 6/36 6/36 6/36 6/60 or less 6/60 or less 6/60 or less 6/60 or less 6/60 or less	6/36 6/60 or less 6/36 6 60 or less 6/18 6/24 6/36 6/60 or less 6/18 6/24 6/36 6/60 or less

—I am, etc.,

West Kirby, Feb. 26. A. STANLEY PARKINSON.

"Give Us the Tools"

SIR,—"The general practitioner is the backbone of the country's health services" . . . we know that. We have heard it a thousand times, almost *ad nauseam*. The infantry is the backbone of the Army, but do we send our infantry into battle armed with bows and arrows? Somebody, the infantryman himself, would have something to say about that! Yet the general practitioner, having been trained in his school to the use of the technical developments of medicine which are in routine use, is sent out to fight in practice with a little leather bag! Oh yes! He can certainly obtain the advice and help required for his patients from the specialists and the hospitals, but he himself is barred from the fun of the game, and from exercising the skill and knowledge he acquired during his years of training and in his hospital appointments. In time, through lack of familiarity, the laboratory and the *x*-ray department become to his mind either awe-inspiring concerns which, like the slot machines, deliver ready-made diagnoses in return for hard cash, or they seem unnecessary and cumbersome complications of the modern machine-mad world. Some of his patients do not come back to him; some regard him as only fit to treat the minor disorders, not the real illnesses. Hence, after a few years of struggle and an increasing sense of frustration, many give it up, and really do become doctors only fit to treat the most minor disorders; and who can wonder at it?

The statement that clinical sense and not the laboratory aids reigns supreme in medicine is just reactionary nonsense *if it implies* that the aids to diagnosis are luxuries with which the "good practitioner" can dispense. The practitioner can perceive anaemia, discover glycosuria, hear a cough, record fever, and suspect cystitis. He can feel the irregular irregularity of the pulse, but he often cannot make the diagnosis without the aid of the laboratories and other special departments. But instead of having direct approach to these essentials he has to refer his patients to the specialist at an out-patient department at a hospital! The evils resulting from this are progressive. It is a serious thing if the backbone of the medical profession suffers from osteomalacia!

The system is bad, too, for the specialist, who has to deal with a glut of easily diagnosable disorders (given the necessary facilities), and cannot devote enough of his time to the few cases which really call for his skill. Anyone who has seen rows and rows of patients on hard benches at the hospitals will pity both the unfortunates sitting there and the physician or surgeon who, somehow or other, has got to "get through them." Finally it is bad for the patient, and medicine exists for the patient—not vice versa! He wastes time, and time is vitally important to the working people—so important that many will not report to their doctors or attend the hospitals until they are seriously ill, when curable disorder may have become incurable disease. Furthermore, it cannot be good psychologically for the patient to lose confidence in his doctor and go for treatment to the hospital.

The logical remedy for this state of affairs is apparent. The practitioner must have direct approach to the more common aids to diagnosis. I don't want to equip my infantryman with a tank: the specialist handles the tank, just as our specialists handle the cysto-, gastro-, and bronchoscopes, need calcium balances, and employ bone marrow investigations. But he must have a bayonet, a grenade, and a tommy-gun: he must have immediately available blood counts, blood ureas, blood sugars, sedimentation rates, sputum tests, microscopical and simple cultural examinations of the urine and faeces, and there must be an *x*-ray plant with a competent radiographer and radiologist, and possibly an electrocardiograph, at his service. And just as the Army has its Service corps, so should the practitioner enjoy the services of a trained nurse who could collect and examine specimens, take and record weights, prepare and sterilize instruments. The doctors should shut down their surgeries at their houses. They should be grouped together at a building where all these facilities are available. Here, too, would be their minor operation theatre, their mess-room, and their library. Co-operation and discussion would raise the standard of professional achievement, and those on the councils who deal with health problems could learn at first hand what the doctors need. The bad old times of "everyone for himself and his little leather bag" must go. And they will only go if the younger, more alive members of the profession, including medical students, residents, and the men in the Services, clamour and demand that they shall go. We must make a vociferous nuisance of ourselves that we may be given the tools with which to work. Only with the tools can we accomplish our task.—I am, etc.,

London, S.E.13, March 6. E. MONTUSCHI.

Mobile Unit in Action

SIR,—Your correspondence recently has revealed such a wide diversity of opinion regarding the utility of mobile first-aid units that I am prompted to contribute our experience.

Our particular unit has been called out to ten incidents, and has treated over fifty casualties—not many perhaps, but it is in the quality rather than the quantity of our work to date that its chief merit resides. Our casualties almost without exception have been trapped under debris for periods varying from one to nine hours. We have been able to improve their chances of survival by: (1) our facilities for shock and wound treatment while they were trapped and after they were rescued; (2) proper supervision of the final stage of the rescue operations, ensuring by accurate diagnosis and appropriate precautions that neither their injuries nor their shock were aggravated

by hasty removal or careless handling; (3) detaining them at our operational centre (a hall or a house adjacent to the incident) until they were sufficiently recovered from shock to undertake, in the case of hospital casualties, the ambulance journey—itself a shock-producing factor; and (4) a correct classification of the nature of their injuries, evacuating them accordingly to hospital, first-aid post, rest centre, or home.

This last function ensures for the casualty the appropriate treatment which his condition demands, and for the casualty services economy of both time and effort by an intelligent distribution of casualties among the various branches of the services. By "intelligent distribution" I mean that casualties are not, as a previous correspondent has remarked, "whisked off to hospitals without any attempt being made reasonably to segregate them." The same correspondent attributed this fault to "the hard-worked ambulance services." This is not so; it is due to the absence of any discriminating classification of casualties by the stretcher parties. Casualties when extricated are in what appears to be a ghastly condition: covered in dirt, dishevelled, and generally in a state which suggests one course of action—hospital. But often even a cursory examination at a mobile unit operational centre reveals that the injuries are negligible, and they respond very well to shock treatment. Stretcher parties working under black-out conditions are in no position to undertake such an examination. Further, by dispatching casualties to hospital immediately they are relieving themselves of any individual responsibility in the matter of "reasonably segregating" them. The result is to encumber the hospitals with casualties who could equally well be handled by first-aid posts.

One other important point about the work of our unit at incidents is that on several occasions one man has been assigned from the unit to act as incident doctor's deputy while the remainder of the personnel have been coping with casualties at the operational centre. This man's job is threefold. He works in conjunction with the rescue and stretcher parties, ensuring that: (*a*) no casualty is carelessly handled—that is, removed from the debris before a thorough examination of his condition has been made, and appropriate precautions taken not to aggravate his injuries; (*b*) as soon as a casualty is accessible, which often happens some time before he can be extricated, such shock treatment as is required is immediately provided and continuously maintained; (*c*) a check is kept on the number of casualties rescued in order that at any stage in the operations an accurate figure is available of the casualties still to be rescued. Concurrently with this strictly "*mobile*" work we have, since we were first established, been augmenting a fixed first-aid post, and have shared the work of treating the post's 240 casualties. Actually the personnel of each post has been trained to do the work of the other, so that they are largely interchangeable.

Naturally the scope of the unit's operations has been determined to a great extent by the severity of the air raids upon this borough, although we could possibly have been used more often. In view of the close approximation of our own average of casualties per incident to the general, it is reasonable to surmise that our experience is the rule rather than the exception—an impression which is reinforced by the account of Southwark's mobile work published in the *Journal* in January (p. 99). I should be interested to know how Southwark's mobile unit is called out; whose specific responsibility is it to send for the unit: wardens', stretcher parties', or Control? Our experience has, however, sufficed both to prove the real necessity for a unit and to testify to the ability of the unit to meet that need. True, some of our functions could equally well have been performed by a smaller unit. But on the other hand there are many boroughs, this included, which have no smaller units, and such experience as we have had has provided first-class training for our personnel to cope with graver emergencies. Again, these smaller units would have to be ancillary to the larger ones, since the larger units have their own definite role in the scheme of the casualty services; and as the larger units are, in our experience, quite successfully doing the job of the smaller ones there is little reason why they should not continue to do so. Any talk of replacing the larger units by smaller ones seems to betray a complete lack of appreciation of the facts. While, as I have admitted, some of the work of the larger units could be done by the smaller units, the reverse does not apply. The larger units, I repeat, have their own definite role in the casualty services—the role of mobile first-aid posts—and so long as the possibility exists that a borough may be "Coventrated," with hospitals and fixed first-aid posts put out of action, so long do the mobile units justify their existence as the first line of reserves of those services. In conclusion, I might add that the work of our unit has been granted no small measure of official recognition by the award of the George Medal to its nurse-in-charge, Sister M. F. Thomas, S.R.N. It was due largely to the work done by her in administering morphine and shock treatment "under the most hazardous conditions" to two trapped casualties that their lives were saved. Use these units more and they will save more lives.—I am, etc.,

F. J. HENLEY,
March 2. M.O., Woolwich Mobile Unit No. 1.

Delay in Treatment of Air-raid Casualties

SIR,—In the *Journal* of February 22 (p. 273) Dr. Margaret Ball and Mr. George Quist discuss a series of forty-three casualties, all apparently the result of one air raid and admitted to the Royal Free Hospital within a short space of time. Three of the patients later developed gas gangrene, and two of these had waited seven hours between admission and operation because of the large number of urgent theatre cases. The authors regard this delay as an important aetiological factor.

This instance of one hospital's receiving so many casualties that serious delay in treatment is inevitable is not an isolated one. It appears to be usual in London for ambulances to take all patients from one "incident" to one hospital, generally the nearest one, while another hospital less than a mile away may have no admissions. This policy of the London ambulance authorities is bound to result in delay in treatment. Many patients have multiple injuries, and they may require over an hour each in the operating theatre, with the result that the wounds dealt with at the end of the list have infection already established. In order to enable treatment to be undertaken at the earliest possible moment the casualties should be distributed to several hospitals and not all taken to the nearest.—I am, etc.,

NORMAN WHITE.
University College Hospital, London, W.C.1, March 11.

Shelter Policy

SIR,—With reference to Dr. Bushnell's letter (March 8, p. 381) on shelter policy, I would like to put forward certain considerations, although I feel doubtful whether even at this late hour any effective challenge will be made by a large body of the profession, or would have much effect if made. The great majority of medical men are not interested in shelters; they are too occupied with their own business. The official view would be that we are sufficiently represented by the Horder Committee, and those who disagree are usually accused of being some kind of "-ist." The B.M.A. has not moved in the matter in any representative manner, either centrally or locally; in any case there would be differences of opinion among its members.

As we have been told, the official policy of the Government, followed by local authorities and reflected in the Horder Committee (or at any rate stated by Lord Horder), is to encourage "dispersal" and its corollary "domestic shelters"; therefore it does not believe in the necessity or practicability of bomb-proof shelters. The stress laid on fire-fighting, and the urging of the population to stay in their houses, protected by Andersons, Morrisons, and cellars, is said to enhance morale. That mothers, children, and the aged should be exposed to the risk of being killed because this is good for morale may sound fantastic, but seems a logical conclusion from the premises—even if they are all evacuated, for there are few shelters in country districts.

After the November raids many hundreds if not thousands of the population in heavily bombed areas evacuated themselves nightly, often on foot, either to shelters in the suburbs (otherwise unused) or to fields and hills miles from this city. The morale of these people is splendid, let there be no mistake about that; but prolonged, intensive raids are more than flesh and blood will stand. Yet these people are being provided with small brick surface shelters in backyards. In fact, policy appears to be dictated by doctrinaire-theory rather than by

observing what happens or taking into account the psychological needs of the situation.

I am not saying that the official policy may not be right, but merely implying my own views or prejudices in the matter and stating certain facts of observation in one locality. There is always a certain amount of "projection"—of personal instinctive and acquired reactions and sentiments—in whatever policy anyone holds, but the still small voice of reason can prevail—if re-echoed long and loudly. Therefore one can but hope that medical men who are not satisfied will join in putting forward the physiological and psychological needs of the population, with insistency, to the authorities; as you, Sir, and Sir John Orr have suggested is our duty.—I am, etc.,

Birmingham, March 10. CHARLES BURNS.

Optimum Calcium Requirements

SIR,—Miss Leitch has challenged our contention that arteriosclerosis is prevalent among the affluent classes. Here is our reference: *Arteriosclerosis*, by Edmund V. Cowdry, Macmillan, 1933, p. 226. That calcium affects renal function is an established fact apart from the formula. Our rabbit experiments comprising considerable material will be published later, and more details will be found in the report of a parallel investigation due to appear somewhere else. The idea that people under low calcium intake may suffer from some occult disease which nobody can detect is too fantastic to deserve a moment's consideration.

Large retention of calcium is a peculiarity of middle age. Similar results were obtained by us with regard to protein retention. Our table consists of averages, and individual high faecal calcium was submerged in the averages. But the main reason for a low faecal calcium is a large retention. Only when calcium is no longer absorbed does a large percentage pass via the faeces. We have had a great deal of experience of this type of work, as our various publications show. Children and pregnant women require other items of food as much as calcium, which can only be supplied by milk. The latter cannot be replaced by bread calcium. The fortified loaf concerns only the adult population, which requires but little calcium.

Now to the core of the problem. It is quite impossible for a person to remain in a negative calcium balance permanently without exhibiting definite evidence of calcium deficiency. It is certain that the whole adult population of this country who do not exhibit calcium deficiency are in calcium balance whatever their intake may be. Calcium minima obtained by experiment depend to an important extent upon the amount of calcium the subject is in the habit of taking. It is very likely that when the calcium intake is low some kind of conserving mechanism becomes operative. True minima of calcium requirement are unknown. These can only be obtained by prolonged clinical observation. As far as optimum requirement is concerned, an amount which fills the reservoirs and supplies the daily needs will, when saturation is attained, supply more than the needs, and a part of the surplus will leave via the kidneys. The latter organs will therefore work unnecessarily and calcium will be circulated in the blood, already saturated—a factor which favours deposits.

The vital problem arises whether a calcium intake which just meets requirements and does little towards filling the reservoirs, or one which fills the reservoirs to overflowing, or one which is between the two extremes, is the ideal. No data whatever are available to judge which is the best, and the choice of one or the other is merely arbitrary. Only prolonged clinical observation can show which is the ideal. We find a similar phenomenon with regard to the fat reservoirs. Clinical experience has taught us that the average expectation of life of those who fill these reservoirs to full capacity is much below that of those who consume only sufficient to cover the needs.

The investigator does not know the real minima. He does not know whether the amount of calcium necessary to fill the whole or part of the reservoirs or which leaves them empty is the ideal. He does not know whether the marginal safety calcium is necessary at all, for there may be as much danger in too much as too little calcium, and the figure of 50% of marginal safety is purely arbitrary. It will be seen that when these experts in language of the exact sciences tell us of the exact ideal calcium requirement per lb. weight they deceive themselves and deceive us. Theirs is a dangerous form of ignorance, for they do not know that they are ignorant. The requirement figure is artificial, unsupported by any evidence, and to estimate calcium intake by money income is not a method to be used in exact science. No direct experimental evidence whatever is available that a section of the community is under a permanent negative calcium balance. A number of unknown quantities are strung together and a heavy superstructure is built on this insecure foundation. It is sheer lunacy that such a far-reaching scheme as entailed in the Government's proposals should be set up on such a flimsy basis. The type of laboratory work under review, if correlated with clinical findings, has a limited value. If not checked by clinical observation it becomes a fantasy without value. In my view it is a grave public scandal that millions of perfectly normal, perfectly healthy adults should be compelled to consume extra doses of such a potent substance as calcium for no reason whatever. A large number of middle-aged people who exhibit evidence of kidney damage, etc., would suffer injury from this extra chalk. In my view it would be discreditable to our profession if we tolerated these proposals; and I appeal earnestly to the Medical Research Council to pause before committing themselves to this criminal folly.

I want from your correspondents a simple answer to a simple question: What is the percentage of the adult population who suffer from calcium deficiency which can be detected by any known method, clinically or in the post-mortem room? The proposal could only be justified if a considerable number of the adult community show evidence of deficiency.

Sir, you are aware that the Government proposals have nothing to do with this war. They have been proclaimed as a great reform which would make us all healthier. In my view the added calcium can serve no useful purpose, for it cannot replace milk.—I am, etc.,

Liverpool, March 1. I. HARRIS.

*** In a leading article on February 22 (p. 281) we made it plain that in our opinion the proposed addition of calcium to flour in wartime was a sound nutritional measure. We must disagree again with Dr. Harris, and suggest to him that a large retention of calcium is not a peculiarity of middle age, and that there is no proof at all that "a large number of middle-aged people who exhibit evidence of kidney damage, etc., would suffer injury from this extra chalk." Dr. Harris states: "Children and pregnant women require other items of food as much as calcium, which can only be supplied by milk. The latter cannot be replaced by bread calcium." If this sentence means that milk calcium cannot be replaced by bread calcium, it is wrong. If it is taken to mean that milk itself cannot be replaced by bread calcium, we would point out that no one has ever suggested the contrary. In view of the malnutrition which has existed among the poorer sections of the population, and which war conditions may easily aggravate, we find entirely misleading Dr. Harris's statement that "it is a grave public scandal that millions of perfectly normal, perfectly healthy adults should be compelled to consume extra doses of such a potent substance as calcium for no reason whatever."—ED., *B.M.J.*

Invalid Diet and the Egg Shortage

SIR,—I am concerned about the country's production, or rather elimination, of that outstanding article of an invalid's diet—the egg. Since meat for beef tea is difficult to obtain, though the meat ration may be sufficient; since fruit is scarce and fish prohibitive; since milk prices have turned that commodity into a luxury, should not some encouragement be given to egg production? While large mixed grills are still obtainable in London restaurants the invalids and convalescents in home surroundings have a thin time.

Eggs cannot be imported to any extent. Poultry stocks through lack of feeding-stuffs have to be reduced to one-sixth. Poultry farmers who have specialized in the economic production of eggs and table fowls go out of business. A reduction from 3,000 hens to 500 ensures this. Locally raised poultry food must to some extent be in the hands of mixed farmers

VITAMIN B_6 DEFICIENCIES

Some recent findings...

CLINICAL experience, following biological experiment, has shown the usefulness of aneurin (B_1) in many conditions now known to be signs of dietary deficiency. Increasing the regular daily intake of Vitamin B_1, by the use of Bemax, not only improves the general health but also prevents the recurrence of the deficiency symptoms.

Considerably less is yet known about Vitamin B_6, but biological experiments with the pure vitamin have proved useful in various syndromes. Improvement has been recorded in certain cases of idiopathic epilepsy, in amyotrophic lateral sclerosis, and in hypertrophic muscular dystrophy. Decreased stiffness and rigidity have followed its use in non-postencephalitic parkinsonism.

The particular deficiency symptoms which have responded to Vitamin B_6 administration are extreme nervousness, insomnia, irritability, cramping abdominal pain, muscular weakness and rigidity with difficulty in walking.

Bemax is probably the richest of all dietary sources of Vitamin B_6 and its regular use should therefore be of real benefit to patients showing groups of the above symptoms and signs.

The Vitamin and Mineral Constituents of BEMAX

	Approx. daily human requirement	*One ounce Bemax supplies*	
		weight	*% of daily requirement*
VITAMIN B_1 (aneurin)	mg. 2.0 (665 i.u.)	mg. 1.2 (400 i.u.)	60
VITAMIN B_2 (riboflavin)	2.0	0.9	45
P.P. factor (nicotinic acid)	5.0	1.1	22
VITAMIN B_6 (adermin)	?	richest source	probably 100

BEFORTISS (Brand) **Concentrated Vitamin B**
Tablets. 200 i.u. and 2 mg. per gm. For high dosage of the B complex.
Ampoules. 2, 10 and 20 mg. For high Vitamin B_1 dosage.

FERTILOL (*Wheat germ oil*) **Capsules**
A highly active stable source of Vitamin E.
For the treatment of habitual abortion, dietary sterility and certain neuro-muscular degenerations, etc.

COMPLEVITE Tablets
Vitamin and Mineral supplement.
To make good the recently revealed deficiencies of vitamins and minerals in the average daily diet.

PREGNAVITE Tablets
Vitamin and Mineral supplement.
To ensure an *adequate* supply of vitamins and minerals to meet the special requirements of pregnancy.

'Proscabin' is an emulsion of benzyl benzoate. It is simple in use and has the additional advantage of being *non-staining* and *non-irritating*. 'Proscabin' can be applied to infants and children and to patients suffering from sulphur dermatitis.

In many instances 'Proscabin' is successful within twenty-four hours.

Note: Cards containing instructions for the patients can be supplied on request.

AVAILABLE IN BOTTLES OF 4 OZS. AND 40 OZS.

(as opposed to poultry specialists), who will eventually produce most of the eggs available in the country on non-economic lines. How many of these will filter through to invalids, hospitals, or even to the town-dwelling working man, who might welcome a fried egg on his meatless day, this year will show. In the meantime, will not our profession show some mild interest in the fate of the hard-working pullet?—I am, etc.,

Hexham, March 10 RICHARD BELL

Supplementing the Dietary

SIR,—In the *Journal* of March 8 (p. 381) Dr. Joseph Jones writes especially with regard to the shortage of protein. Is there any reason why separated milk should not be used? A cheese used to be made from it in Dorset which was sold at the very low price of 3d. a pound. In the form of dried separated milk its use was strongly advocated by Mr. Eustace Miles. Casein is the only, or an important, constituent of various well-known advertised preparations. Its value is equal to that of any form of lean meat, white fish, or fowl. It is used unfortunately in industry for the manufacture of various articles which simulate those made from pottery or bone; its use as a food would seem much more important.—I am, etc.,

Bournemouth, March 10. F. C. BOTTOMLEY

Natural Bran in the Treatment of Constipation

SIR,—Dr. Parkes Weber points out in your issue of February 15 (p. 252) that the Government's prohibition of the manufacture of prepared bran will cause hardship to those sections of the community who depend on this product for the prevention of constipation. The following may therefore be of interest.

I have used natural unprepared bran in the treatment of constipation in the Royal Navy for at least ten years. It has invariably been successful, provided the dose has been maintained at an adequate level. Indeed, by the laws of Nature it *must* be successful. I can only say, as regards the reported resistance of "spastic" cases of constipation to cellulose-stimulation, that I have not found any such cases when using natural bran; any failure has always been due to inadequate or irregular dosage.

The dosage varies (*a*) with the individual, and (*b*) with the amount of cellulose taken in the food. As regards item (*a*), it may be noted that the more northern the race the less cellulose is taken in the food, owing to the progressive diminution in plant life that occurs, and vice versa. The Eskimo, for example, takes almost no cellulose at all under natural conditions, whereas the African native takes a vast quantity. It follows that there is scope for great differences in the cellulose requirements of different individuals. Thus, a fair-complexioned individual in this country, representing some northern (e.g., Viking) race, would normally require less cellulose than a dark individual representing a more southern (e.g., Latin) race. As regards item (*b*), it is clear that the more cellulose taken in the food (e.g., fruit and vegetables) the less is required to be made up by the taking of bran.

In actual practice the dosage of natural bran varies from a teaspoonful to two tablespoonfuls before each meal, but the larger dose is seldom required except in bed patients. It is essential to *start* with the larger dose and reduce it, as results occur, until the correct maintenance dose is established. Regularity of dosage is fully as important as the quantity of dosage. The reason for taking it before each meal is that proportionately less food is then eaten during the meal, and so no indigestion results; but if the appetite was fully satisfied by a meal and then a large dose of bran was taken, overloading of the stomach, with attendant discomfort, might be expected. The bran may be taken in soup or with milk, or be just washed down in a glass of water. It is unexciting to take but not unpleasant. Bran is, of course, prophylactic against constipation; it is useless for an occasional bout of this trouble. As it takes at least forty-eight hours, and sometimes ninety-six, to have any effect, it is desirable to start off a case of established constipation with an enema, and possibly another forty-eight hours later; a third is never required.

The great advantage of natural bran is the low cost (a few pence a month). People who are reasonably well off can nearly always avoid constipation by taking an *adequate* amount of fresh fruit and vegetables, but this knowledge is of little comfort to the indigent poor. For them unprepared bran is the sole natural aperient they can afford to buy. Natural bran is readily procurable. In H.M. ships the canteen can always carry a stock of it. On shore corn-chandlers stock it, and bakers can easily order it.

The question may be asked whether there is any risk of contracting actinomycosis from natural bran. The answer is definitely "No." The fungi found on wheat bear no more relation to the superficially similar *Streptothrix actinomyces* than do the bacilli of Timothy grass to the superficially similar tubercle bacillus. Natural bran is as safe to eat as any other raw vegetable or fruit.—I am, etc.,

Feb. 26. T. L. CLEAVE, Surgeon Commander, R.N.

Acute Abdominal Pain after Opium Medication

SIR,—I have been most interested in Dr. J. B. Williamson's letter (February 8, p. 215). It recalled to me some experiences which I recorded in a short memorandum in your *Journal* in 1917 (1, 72). The record is as follows.

Four cases of severe abdominal pains following large medicinal doses of opium or drugs containing its derivatives have recently come under my observation. In each instance the symptoms were such as might easily lead the observer to believe at first sight that he was confronted with an abdominal condition requiring surgical interference.

Case 1 was of a man aged 25 suffering from toothache, who took 1 grain of morphine hydrochloride by the mouth. Two hours after the administration he awoke with violent abdominal pains coming on in spasms. He was sent to hospital as possibly a case of perforated duodenal ulcer.

Case 2 was of a man aged 37 suffering from influenza. During the course of an evening he took five tablets of 5 grains each of Dover's powder, which contains 10 % of opium. The patient awoke about two hours after the last dose with violent abdominal pain.

Case 3, a man aged 23, was admitted to hospital suffering from an injury to the lower part of one thigh; he complained of great pain and was given a hypodermic injection of heroin, 1/6 grain. A quarter of an hour afterwards he began to cry out with intense pain in the upper part of the abdomen. He was apparently suffering very much, as he began to writhe about, forgetting for the time being the injury to his thigh. He continued thus for half an hour, when he was given another dose of heroin, 1/6 grain, which apparently afforded no relief and the dose was repeated; after this he became quiet and ceased to complain.

Case 4 was of a man aged 24 suffering from nasal catarrh and bronchitis, who took 2 oz. of Brompton mixture, which contains liquor morphinae hydrochlor. Between two and three hours later he was awakened by severe cramp-like pains in the region of the stomach.

These cases resemble each other very closely in their symptoms: spasms of gripping pain in the epigastric and left hypochondriac regions, coming on at intervals of a few minutes, lasting about a quarter of an hour, and so severe as to double the patient up and cause him to groan. The symptoms in the first two cases lasted for about an hour and then passed off completely without treatment other than hot bottles. The third case at the end of an hour was also free from pain, but by that time he had received in all 1/2 grain of heroin hypodermically, and it is likely that the last injection placed him so deeply under the influence of the drug as to relieve him of the consciousness of pain. Case 4 suffered for about half an hour, when he was given 1/120 grain of atropine hypodermically, after which he got almost immediate relief. In none of the cases was there any vomiting or nausea. The pupils in each instance indicated by their contraction that probably opium had been taken, and on inspecting the abdominal wall the upper part was distinctly rigid and respirations were short. In one case both recti stood out very prominently. The patients resented palpation of the abdomen, as it appeared to tend to start the spasms. On inquiring into the histories of the individual cases, none of them had

previously had any condition resembling that described, and subsequent to the attacks passing off all seemed perfectly well.

It would be interesting to know if other practitioners have had cases of this kind, as these seem to demonstrate an action of the drug which is not generally recognized. Inquiry among my medical friends reveals only one instance of acquaintance with this peculiarity of the action of opium, and in this case a well-known surgeon had a personal experience of these unpleasant symptoms. Opium causes convulsions in cats and amphibians, and a veterinary friend informs me that a severe colic is known on occasion to follow administration of morphine in horses.

In the late Sir Lauder Brunton's *Textbook of Pharmacology, Therapeutics, and Materia Medica* the fact that opium in certain conditions stimulates intestinal peristalsis is noted. He seems to have used it occasionally in very small doses, one drop or even half a drop of tincture of opium, in certain forms of constipation—for example, that caused reflexly by ovarian irritation.—I am, etc.,

London, March 12. H. P. WINSBURY-WHITE.

Operation for Acute Appendicitis

SIR,—Some years ago I saw Prof. Nordman at the Martin Luthers Krankenhaus, Berlin, use a method of operating for acute appendicitis that I have not so far seen in England. So far I have used it in some twenty-five cases. The incision is placed a fingerbreadth above and parallel to the outer half of Poupart's ligament—two to three inches long according to the amount of adipose tissue present. The external oblique is divided in the direction of its fibres and retracted, and a small intermuscular septum in the internal oblique running downwards and inwards from the anterior superior iliac spine is seen along this. As in McBurney's incision the fibres of the internal oblique and transversalis are separated by blunt dissection and the peritoneum opened.

In about one-quarter of the cases the appendix presents, in one half the colon. The anterior longitudinal band is seized with smooth forceps and gently drawn upwards until the root of the appendix is seen: this is seized with strong forceps and the appendix delivered. If the omentum presents it is thrown upwards. The fingers do not have to be introduced into the wound at all. The skin wound does not stretch. All my cases have been early ones without marked adhesions, but I seem to remember that some years ago Sir Hamilton Ballance advocated a similar incision but "muscle cutting" as the best approach for acute appendicitis.

A point about acute appendicitis that I cannot remember having seen noticed is the change in position of the appendix as the inflammation progresses: the swelling and shortening of the mesentery in the region of the ileo-colic artery drawing the caecum upwards and inwards. Dr. Crabtree of Nelson tells me that in some 6,000 routine opaque gastro-intestinal examinations he has not found the caecum elsewhere than in the iliac fossa, which seems to be the normal dwelling place.—I am, etc.,

Nelson, March 5. OWEN WILSON.

Malignant Measles?

SIR,—In reply to Dr. Audrey Baker's letter (March 8, p. 380) dealing with a so-called case of malignant measles, I am not clear on what grounds such a diagnosis was justified. The case quoted was undoubtedly an unusual one, but I would suggest that the more correct diagnosis was one of suprarenal haemorrhage. This interesting condition occasionally sets in during the first year of life as part of a rapidly fatal illness. The symptoms set in suddenly with fever and vomiting, and scattered purpuric spots quickly follow. Death usually occurs within twenty-four hours. I met such a case a few months ago, and post-mortem examination confirmed the diagnosis.

I notice Dr. Baker makes no mention of Koplik's spots, exposure to infection, or, in fact, of any of the usual symptoms associated with measles, and, in consequence, I venture to suggest that her case was one of haemorrhage into the suprarenals.—I am, etc.,

Aylesford, March 13. GEOFFREY P. GOODWIN.

SIR,—Though the case described by Dr. Audrey Baker (March 8, p. 380) was clearly both malignant and "black," it is a mistake to regard "blackness" as a sign of malignancy or malignancy as a cause of "blackness." I have met a number of cases of "black" (haemorrhagic) measles, but not one of the patients has died or shown any sign of malignancy, and some of the cases have run a decidedly mild course. A friend tells me that "black" measles was quite common in Ireland fifty years ago, and that the fatality was so high that "black" was regarded as almost synonymous with malignant, but that in those days the children were commonly poor, half-starved little creatures, and this might account for the high fatality and perhaps also for the prevalent "blackness." The patients in my own cases were all well nourished and generally in good condition, which accounts for the absence of fatality but leaves the pathology of the blackness an open question. At any rate, the terms should not be employed as though they meant the same thing.—I am, etc.,

Ambleside, March 13. J. PRICE WILLIAMS.

Continuous Pentothal Anaesthesia

SIR,—One of the questions most frequently asked by practitioners who are desirous of employing continuous pentothal anaesthesia is: "What are the difficulties that may occur?" So far as I can judge these have not been explained in detail, and having employed continuous pentothal in over 500 cases, many of which were battle casualties, I think that I have encountered most of the difficulties.

1. Fibrillation of Muscles.—In most cases only the masseter is affected, but it may extend all over the body. It is very similar to ether tremor, and disappears with the introduction of more pentothal.

2. Sudden Muscular Contraction.—This may occur spontaneously or be due to surgical stimuli. The commonest muscles to contract are the pronator quadratus and pronator radii teres, thereby adding to the difficulty of the injection. Very occasionally a rhythmical contraction may occur; one patient kept flexing and extending a knee-joint after 40 c.cm. of a 5% solution (2 grammes) had been given.

3. Very Shallow Breathing accompanied by Cyanosis.—This is very common, but is quickly remedied by a few breaths of carbogen under slight pressure. I think that continuous pentothal should not be employed by those inexperienced in its technique unless CO_2 and O_2 is available.

4. Persistent Coughing.—This has occurred in a few cases but is usually overcome by increasing the dosage. One patient was given 50 c.cm. of a 5% solution (2.5 grammes) and even then the coughing was not satisfactorily controlled. This is most unusual.

5. Severe Laryngeal Spasm.—I have had only three cases of this condition, all of which were preceded by coughing. The operation in each case was for haemorrhoids. These cases were rather alarming, but eventually responded to O_2 under considerable pressure.

6. As patients who have had large doses sleep for a considerable time afterwards, it is advisable to insert an airway before they return to the ward.

The post-anaesthetic complications are: (1) Numbness of the skin of the arm: this is transient and is due to the introduction of pentothal into the tissues. (2) Bruising of the arm. (3) Restlessness; this occurs only when under 15 c.cm. of a 5% solution has been given. (4) Thrombosis of the vein; I have had only one case of this condition.

In conclusion, these difficulties, with the exception of shallow breathing, are uncommon, and I hope will not deter those who are desirous of employing this very valuable and pleasant anaesthetic.—I am, etc.,

Feb. 14. R. HASTINGS MOORE.

Pentothal Sodium in Acute Hysteria

SIR,—I have had an opportunity of confirming Frankel's experiment mentioned in the *Journal* of January 6, 1940 (p. 14) on the use of evipan in a case of loss of memory, and agree that intravenous barbiturate is useful in dramatically relieving an acute hysterical state of mind. In this case, too,

there was "something desperate in the history which it was essential for the patient's peace of mind that he should forget."

A soldier was brought to hospital by the guard. He had suddenly become unruly and had thrown his money far and wide. There was complete "blocking" and no response to direct questioning; meanwhile the patient continued in a state of increased psychomotor activity with low moanings and rapid respirations. Careful physical examination ruled out signs of organic disease, while the fluttering eyelids were so typical of hysteria that the upward rolling of the eyeballs which occurred when an attempt was made to see the pupils merely served to confirm this diagnosis. In short, the picture was typical of the hysteric who lives from hand to mouth and who obtains a bed at hospital by defeating the young casualty officer with practised ease, and to whom the hysterical attack is an accomplishment as well as a profession. By giving 4 c.cm. of pentothal sodium solution (1 gramme in 20 c.cm. aq. dest.) sleep of an hour's duration was produced, and when seen three hours later the patient was rational and wished to rejoin his unit. It was now discovered that this man had been ordered over-seas immediately preceding the acute symptoms, hence the mental conflict. The sedative action of the barbiturate relieved these inhibitions, and the patient was now able to appreciate that malingering meant a court martial, so all idea of disobeying orders was given up forthwith.—I am, etc.,

J. A. MAXWELL CAMERON
Capt., I.M.S.

Karachi, Jan. 15.

Nurse Anaesthetists

SIR,—The correspondence on nurse anaesthetists is very interesting, but from a surgeon's point of view not very convincing.

If anaesthetists wish their calling to be considered essential, then they must be prepared to attend and administer to every routine hospital surgical operation list. This, in my experience, with few exceptions they seldom do. Often a 'phone message arrives to indicate that they cannot attend, and only occasionally do they arrange for an adequate deputy. Usually a house-physician or a house-surgeon, often newly qualified, has to give the anaesthetic, and only if an intratracheal anaesthetic is necessary must the operation be postponed. A surgeon never allows a house-surgeon to do an operation until he has been trained and tested, yet hospital anaesthetists often leave operation lists for untrained resident staff. Personally, I consider that a trained intelligent nurse is quite capable of giving an ordinary good general anaesthetic, and I have occasionally had to operate with a nurse giving the anaesthetic and with complete satisfaction. I consider that a trained anaesthetist is a luxury for a surgeon, but a newly qualified doctor is often a sore trial, and too often specialist anaesthetists leave us none other but these as deputies. In many hospitals I think that a trained nurse anaesthetist would be of great value, and the correspondence in the *Journal* to the contrary has not convinced me. I think that Cambridge is to be congratulated for raising the subject.—I am, etc.,

F. MACG. LOUGHNANE.

London, W.1, March 10.

A. C. Drogendijk (*Brux. méd.*, 1940, **20**, 617) describes the various methods employed for preventing the occurrence of post-vaccinal encephalitis—namely, vaccination within the first two months of life, while the child still retains some passive immunity transmitted from the mother, which it loses later; choice of a certain season of the year, although statistics do not prove that the risk of encephalitis is greater at one season than at another; the use of a very diluted lymph (cases, however, have occurred after a 1 in 100 dilution); and reduction in the number of insertions. Although this reduction cannot be shown to be of much effect, there is no need for multiple scarifications if one is enough. The other prophylactic methods consist in the employment of fractional vaccination, intracutaneous or subcutaneous vaccination, vaccination of the mother during pregnancy or lactation, injection of an anti-vaccinial serum, inoculation of a killed vaccine, and modification in the mode of preparation of the vaccine. None of these methods, however, has proved to be absolutely efficacious.

Obituary

T. A. ROSS, M.D., F.R.C.P.

We regret to announce the sudden death at St. John's House, Smith Square, Westminster, of Dr. Thomas Arthur Ross, who was the first director of the Cassel Hospital and held that post for fifteen years.

He was born in Edinburgh in 1875, the son of Thomas Ross, LL.D., and after schooldays at the Edinburgh Academy entered as a medical student at the university and graduated M.B., C.M. in 1897. He proceeded M.D. in 1901 after serving as resident physician and resident surgeon at the Royal Infirmary. He was then appointed physician to the Royal National Hospital for Consumption at Ventnor, where he was in general practice for sixteen years. When the Cassel Hospital for Functional Nervous Disorders opened at Swaylands, Penshurst, in 1919 Dr. Ross became its medical director and thenceforward devoted himself entirely to the neuroses and psychotherapy. He was elected a Fellow of the Royal College of Physicians of Edinburgh in 1919 and a Fellow of the Royal College of Physicians of London in 1933 after taking the Membership in 1926. He wrote three books: *The Common Neuroses and their Treatment by Psychotherapy*, which reached a second edition four years ago; *An Enquiry into Prognosis in the Neuroses*; and an *Introduction to Analytical Psychotherapy*. In the central work of the British Medical Association, which he had joined in 1898, Dr. Ross served on three special committees: the Committee for Research in Mental Diseases, the Psycho-Analysis Committee, and the Mental Health Committee. He was twice married and had two children: a son who died whilst still a medical student, and a daughter, Dr. Jean Durrant, who is an assistant medical officer at the Maudsley Hospital.

Sir ARTHUR HURST writes:

During the seventeen years he was in general practice at Ventnor Ross was greatly interested in the treatment of patients suffering from functional nervous disorders, many of whom were sent to him by Victor Horsley, who was one of the few people in those days who was not merely bored with his neurotic patients. At first Ross treated them by the Weir-Mitchell method, which was at that time almost universally used for all kinds of neuroses. The patients were kept in bed, isolated from their friends, over-fed, and massaged. For some years he met with great success. He then gradually lost his early enthusiasm for the treatment, and as he did so his results deteriorated. He soon realized that the change was not in the treatment, which remained unaltered, nor in the patients, but in himself. He had slowly come to the conclusion that exhaustion was not the sole cause of the neuroses and that his results had been largely due to his belief in the treatment. By 1914 he had learnt the lesson that the cures were the result of faith and hope, and that the ideal psychotherapy is to teach the patients how they can reacquire faith in themselves. He acknowledged that there were cases where psycho-analysis was required, but there was a large majority in which better results could be obtained by simple methods. This conclusion did not in any way diminish his appreciation of Freud's contributions to our knowledge of the neuroses, although it was to the encouragement and advice he received from Henry Head and the writings of Dejerine that he felt chiefly indebted for his success as a psychotherapist. "The Freudians long ago gave up the general physician as a hopeless person who is unteachable, and it seems desirable," he wrote, "that those of us who are in the first instance physicians and only in the second psychotherapists should not give up the Freudians." It was for this reason that he published in 1932 his *Introduction to Analytical*

Psychology, in which he emphasized what seemed to him to be good in analysis without dwelling too much on the bad.

From 1917 to 1919 Ross was attached to the Springfield war neurosis hospital. In 1919 Sir Ernest Cassel decided to give a large sum of money for the advancement of some pioneer work in medicine. He asked for three schemes from which to choose. He adopted Sir Maurice Craig's suggestion of an institute for the treatment of neuroses in patients of moderate means, and the Cassel Hospital at Swaylands, Penshurst, thus came into being. Craig had no doubts from what he knew of Ross that he was the ideal man to be the first medical director of the new hospital; and the future was to show how wisely he had chosen. After a preliminary visit to a number of American clinics Ross began work at this, the first hospital of the kind to be established in Great Britain. His success during the fifteen years he was medical director was remarkable, as innumerable grateful patients and their doctors can testify. His annual summary of the year's work and follow-up of all of his 1,200 old patients was later summarized in 1936 in his *Enquiry into Prognosis in the Neuroses*. This was a most valuable contribution to the literature of psychotherapy and the first and most complete work of the kind to be published. He found that 45% of his patients were well and 25% improved after one year, 40% after three years, and 34% after five years—an unexpectedly good result.

Ross believed that the great bulk of functional nervous disorders can be treated successfully by the general practitioner, and it was in this belief that he wrote his great work on *Common Neuroses*, a worthy sequel to Dejerine's *Névroses et Psychonévroses*. Since its publication in 1923 I have always told students that whatever textbook on medicine they like to read they must supplement it by reading Ross's *Common Neuroses* if they aspire to be successful practitioners. As Ross pointed out, if the general practitioner is to undertake psychotherapy his treatment must be simple and reasonably short, and he will find that it is rarely necessary to refer a patient to an expert psychotherapist for more prolonged and specialized treatment. Ross was convinced that general practice or general medicine was the proper approach to specialized psychotherapy, and he deplored the tendency of the teaching hospitals to choose alienists as their instructors in the subject. He equally deplored the modern tendency for a newly qualified medical student with no postgraduate medical training and no knowledge of the world to set himself up as a specialist in psychotherapy with no broader training and no sounder foundation than a course of instruction at a psychotherapeutic institute.

Ross was a charming companion and it required a very short time in his presence to make one understand how quickly he was able to gain the confidence of his patients and to help them to regain their mental health. All who knew him will agree with Sir Farquhar Buzzard that "his success, both as a doctor and a friend, was due to his personality. Behind the screen of a charming gentleness and modesty of demeanour there lay solid moral courage and transparent honesty of purpose, qualities which even he could not disguise by an inimitable and pawky sense of humour."

On February 19 the death occurred at Ashburton, South Devon, of Dr. THOMAS OATES HALLIWELL at the age of 70. He had been a member of the British Medical Association for thirty-four years. Trained at St. Thomas's Hospital, Dr. Halliwell qualified M.R.C.S., L.R.C.P. in 1894. He practised in his native town of Dewsbury, Yorks, for some years. In 1906 he gained the D.P.H. at Leeds and became medical officer of health and school medical officer for Dewsbury, where he built up the public health service. A serious illness caused him to resign this appointment, but happily he recovered and entered the local government service as resident medical officer at the Stanchiffe Poor Law Institution, which later became the Stanchiffe County Hospital under the West Riding County Council. It was at this post (writes V. R.), which he held till his retirement some six years ago, that Dr. Halliwell's all-round abilities were displayed. As well as being an administrator he was surgeon, physician, and gynaecologist, a type of doctor which has become all too rare. He took great interest in training nurses for the C.M.B., for which he acted as examiner latterly. A man of courtesy and charm combined with a Yorkshire straightforwardness, Halliwell will be missed by his many friends. Those who had the privilege of knowing him in his family circle will remember the culture and hospitality of his home. He was a collector of old china and antique furniture. He took a keen interest in freemasonry. He leaves a widow and daughter. His son, Eric Oates Halliwell, M.R.C.P., practises in Yorkshire.

DR. JOHN ADOLPHUS KENNEDY of Portstewart, Co. Derry, died at Hopefield Cottage Hospital, Portrush, Co. Antrim, on January 4, aged 68. He graduated B.A., M.B., B.Ch. at Trinity College, Dublin, in 1899, and soon after was appointed dispensary medical officer for Portstewart, a post which he held until his death. He proceeded to the M.D. degree in 1904. A member of the North-East Ulster Division of the British Medical Association, Dr. Kennedy was very popular with his medical colleagues, and was held in high esteem by the residents of the town. He was Senior Elder of Portstewart Presbyterian Church and was a member of the Masonic Order.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

On the recommendation of the Faculty Board of Medicine the Senate resolved on March 14 that Grace 6 of October 20, 1939, shall not apply to medical students whose first term of residence is the Michaelmas term of 1942 or a later term. The Grace in question puts into abeyance, until further order, Regulation 8 (*c*) for the M.B., B.Chir. degrees, which requires a candidate for the Final M.B. examination to have obtained honours, or to have attained the honours standard, in the Natural Sciences Tripos.

The following are the dates of Congregations to the end of the Easter term: Saturday, April 26, Friday, May 9, Saturday, May 24, and Friday, June 6, at 2 p.m. There will also be general admissions on Saturday, June 14, at 11 a.m., and on Tuesday, June 17, at 11 a.m. and 2 p.m.

At a Congregation held on March 14 the following medical and surgical degrees were conferred:

M.D.—*C. E. D. H. Goodhart, C. G. Batty-Smith, G. S. W. Organe.

M.CHIR.—*R. C. F. Catterall, *G. Blackburn, *J. S. Ellis.

M.B., B.CHIR.—J. G. Craddock.

* By proxy.

UNIVERSITY OF LONDON

Retirement of Principal

The period for which Mr. H. L. Eason, M.D., M.S., F.R.C.S., was appointed as Principal of the University ends on September 30, and the Senate has decided that the post shall not for the present be filled. Mr. Eason has held the office of Principal since July, 1937, having been a member of the Senate from 1911 and Vice-Chancellor from 1935. He is the President of the General Medical Council, on which body he has represented the University since 1925. The Senate, with the concurrence of the Court, has appointed Mr. Harold Claughton as Acting Principal from October 1.

Postponement of Elections by Convocation

Under an Emergency Statute no elections by Convocation of persons to be members of the Senate will be held in 1941, and those persons who are due to retire on the second Tuesday in May of this year will continue to be members of the Senate until the second Tuesday in May, 1942. Under another Emergency Statute no elections to the offices of Chairman and Deputy Chairman of Convocation are to be conducted before March 1, 1942, and the present holders of these offices will continue in office until May 10, 1942.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the Royal College of Surgeons of England, held on March 13, with Sir Hugh Lett, Bt., President, in the chair, Prof. A. W. Sheen, Mr. W. H. Brown, Prof. John Morley, and Prof. P. J. Moir were elected Members of the Court of Examiners.

The title of Professor of Human and Comparative Anatomy was conferred upon Dr. A. J. E. Cave.

Mr. Eardley Holland was re-elected as the representative of the College on the Central Midwives Board.

Diplomas

Diplomas of Fellowship were granted to the following candidates:

J. E. Richardson, H. Freeman, T. I. Hughes, J. P. Reidy, Katharine M. H. Branson, Janet E. Bottomley, W. W. Wiggins-Davies, Dorothy M. S. Knott, H. L. Brewer, W. N. Campbell, L. Henry, C. W. Maclay, H. Rees, V. N. Singh, A. A. Wearn.

A Diploma of Membership was granted to Mohamed Abdul Hafeez of Osmania University and West London Hospital

Diplomas in Tropical Medicine and Hygiene were granted, jointly with the Royal College of Physicians of London, to the following candidates:

F. I. C. Apted, M. A. Cave, M. A. X. Cochemé, J. J. Dubash, C. L. Ferguson, Brenda Fife, G. D. Harthan, Sara Joelson-Syrop, W. N. Kenrick, H. L. Maclure, D. H. Manson-Bahr, P. J. Pablot, A. E. Seligmann, D. B. Sen, S. B. Sinha, L. H. Turner, W. J. Tyson, A. J. Walker, C. Wilcocks.

Diplomas in Ophthalmic Medicine and Surgery were granted, jointly with the Royal College of Physicians of London, to the following candidates:

H. S. Grewal, F. J. Lorriman, A. Philipp.

The Services

AWARDS AND MENTIONS IN DISPATCHES

Captain Geoffrey Ollivant Brooks, R.A.M.C., has been awarded the George Medal for conspicuous gallantry in carrying out hazardous work in a very brave manner.

Lieut. William Sillar, R.A.M.C., has been awarded the Military Cross in recognition of distinguished services in the field.

Surgeon Commander Francis Laird Cassidi, V.D., R.N.V.R., has been awarded the *Volunteer Officers' Decoration.*

Surgeon Lieut.-Commander Gavin H. Cameron, R.A.N.R., has been awarded the *Royal Naval Volunteer Reserve Officers'* Decoration.

Temporary Surgeon Lieuts. Hamish Alexander Wallace, R.N.V.R. (posthumous), and Daniel Jack Wilkes, R.N.V.R., have been mentioned in dispatches for courage and devotion to duty.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Missing

Surgeon Lieut. Lyon Ramsay Blair, R.N.

ARMY AWARDS

Corrigenda

In the list of officers whose names have been brought to notice in recognition of distinguished services in connexion with operations in the field, March to June, 1940, published in the *Journal* of January 4, two names were misspelt and the initials of five others were wrongly given. Major J. Houston, R.A.M.C., and Lieut. N. C. Rodgers, R.A.M.C., should read Major J. *Huston, R.A.M.C., and Lieut. N. C. Rogers, R.A.M.C.*, and the initials of Captain (Acting Major) A. G. Whitfield, R.A.M.C., Captain L. Evans, R.A.M.C., and Lieuts. W. G. J. Gordon, C. Hope, and J. H. Rose, R.A.M.C., should read Captain (Acting Major) A. G. W. Whitfield, R.A.M.C., *Captain L. F.* Evans, R.A.M.C., and Lieuts. D. G. J. Gordon, G. H. G. Hope, and J. D. Rose, R.A.M.C.

The Colyer Prize was founded in 1926 to commemorate the twenty-five years' service of Sir Frank Colyer as honorary curator of the Odontological Museum. The accumulated income of this fund may be used every third year for a prize for the best original work in dental science, completed during the previous five years, by a dental surgeon educated at any recognized dental school in Great Britain or Northern Ireland, who has not been qualified to practise more than five years at the date of the award. Applications from candidates for the fourth award should be submitted by September 30, together with a general account of their researches, both completed and in progress, to the secretary, Royal Society of Medicine, 1, Wimpole Street, W.1, and marked "Colyer Prize."

Medical Notes in Parliament

The Parliamentary Medical Committee met at the House of Commons on February 8, when Dr. John McMichael of the Postgraduate Medical School, Hammersmith, and Dr. G. O. Barber, medical officer to Felsted School, opened a discussion on post-war medical planning. Debates followed on the future of medical practice. Sir Francis Fremantle was in the chair.

Overruled Decisions of Medical Boards

Dr. MORGAN asked on March 11 what were the general principles applied by the Army Medical Department when it overruled the opinion of civilian doctors in connexion with the examination of recruits for the Army and Auxiliary Territorial Service; when the overruling took place, at medical boards or subsequently; in how many cases the civilian medical opinion had been overruled; and had the civilian doctors been consulted before their opinion had been overruled. Captain MARGESSON said in reply that the opinion of civilian doctors regarding the physical fitness of recruits for the Army and the Auxiliary Territorial Service was overruled only after careful consideration of each individual case by the Army medical authorities, and, if necessary, after obtaining specialist advice. Apart from the examination of a recruit on joining, a disability might come to light during training: on the other hand, the conditions of Army life might improve the physical fitness of a recruit to such an extent as to justify transfer to a higher medical category. Information regarding the number of occasions on which the opinion of the Army medical authorities differed from that of the civilian medical board was not readily available. It was not considered practicable for administrative reasons to consult the civilian doctors on these occasions.

Adjustment in Industry

Dr. MORGAN declared on March 11 that a number of persons employed in war factories had been obliged to cease work owing to muscular strains and neuritis due to constant application to unaccustomed work and that they could not obtain any compensation or special remedial treatment for such injuries. He also said that in many industrial centres adequate and appropriate treatment facilities were non-existent. He asked what Mr. Ernest Bevin was doing to remedy this. Mr. BEVIN answered that in the majority of cases workers adjusted themselves to unaccustomed work after a short period and were not obliged to cease employment during the period of adjustment. He invited Dr. Morgan to give particulars of any contrary cases and promised to consider them.

Hospital Equipment under War Damage Bill

While the House of Lords was in Committee on the War Damage Bill on March 13 Lord LUKE said it was unlikely that hospitals would be as generously treated for equipment as for buildings. They would have to pay a premium for the insurance of the former, and he hoped that would be one which they could afford. They would like to insure a portion of the equipment if the hospital could not afford a premium on the whole. It was possible to carry on without x-ray equipment, but not without an operating theatre. He moved an amendment providing that in the insurance of goods held for charitable purposes the Board of Trade should consult a national, regional, or other body representing the purposes for which the goods were held.

Viscount SIMON, the Lord Chancellor, said the equipment of hospitals and other charitable bodies would be insurable under the business scheme and not under the private chattels scheme, and there would be no limit to the amount that could be covered. The definition of business was wide enough to cover the beneficent work of hospitals. The Board of Trade had consulted the Ministry of Health about hospitals, and the British Hospitals Association was in close touch with that Ministry. Any representations which still had to be made about hospitals would receive sympathetic attention. He gave an assurance that the Board of Trade would consult the Ministry of Health, if necessary, on any questions affecting hospitals which might arise in the administration of Part II of the Bill

and the Ministry would consult the British Hospitals Association. The Board of Trade had power to pay compensation although there had been no insurance. That power would be used to pay compensation for damage occurring before passage of the Bill. It was not intended to compensate hospitals for equipment not insured after the insurance scheme came into operation. Those for whom Lord Luke spoke should communicate with the Ministry of Health to find out which was the best way to proceed.

Lord LUKE withdrew his amendment and the Committee stage concluded.

Army Vaccination Instructions

Mr. VIANT asked on March 18 what instructions had been issued to Army medical officers in regard to the carrying out of vaccinations. Captain MARGESSON replied that the more important points in the instructions issued with regard to vaccination might be summarized as follow: (1) The individual must be in good health. (2) The skin over and around the site for vaccination should be cleansed. (3) The cleansed area must be allowed to dry thoroughly. (4) The vaccine lymph should be applied to this area before scarification is carried out. (5) Scarification should be made with a sharp-pointed scalpel, and should consist of a single linear incision one-quarter inch in length passing through the lymph. The incision should not be deep enough to draw blood. (6) Further scarification or energetic rubbing of the lymph into the incision should be avoided, as this tends to aggravate local reactions. (7) The dressing recommended is elastoplast, which should be applied after the lymph has been allowed to dry completely. Captain Margesson added that vaccination was carried out by scarification. One mark was produced. Revaccination was carried out at intervals of two, five, or seven years following successful vaccination according to local conditions.

Diphtheria in Immunized Edinburgh Children

At the request of Mr. JOHNSTON, the medical officer of health for Edinburgh has extracted from his records the following figures for the years 1938, 1939, and 1940. These figures are approximate, but complete statistics are now being kept for Edinburgh.

	1938	1939	1940
Approx. number of children immunized up to the end of the year	31,000	33,000	34,000
Number of immunized children who contracted diphtheria during the year ..	31	23	9
Number of fatal cases among these children in the year	1	—	—

Doctors' Identification Cards

Dr. MORGAN asked if the Minister of Health was aware of the ease with which doctors might obtain admission on demand to places of military importance without being required to produce evidence that they were in fact doctors. He asked whether the Minister would take steps to see that all doctors were provided, without delay, with identification cards containing their portraits and some authoritative indication that the portraits were those of medical practitioners, in view of the fact that the scheme already proposed for that purpose failed to operate except in comparatively few instances. Mr. ERNEST BROWN replied on March 12 that the majority of medical practitioners had already taken advantage of the special arrangements announced last October for the issue of authorized certificates of occupation. Those who had not done so were still at liberty to take advantage of these facilities. The Secretary for War and he were not satisfied that any need existed for further documents of identification for members of the medical profession. He was therefore not prepared to take the steps suggested by Dr. Morgan.

Staffing of E.M.S. Hospitals.—Dr. MORGAN inquired on March 6 whether, in view of the prevalence of influenza and other non-surgical complaints, Mr. Brown would see that physicians were appointed to those Emergency Medical Service Hospitals where such cases were at present under the care of surgeons. Mr. BROWN answered that the services of a specialist physician were available at every hospital in the emergency hospital scheme, although not necessarily on a resident basis.

Milk Supplies.—Mr. LIPSON asked on March 13 what steps were taken to ensure that an adequate supply of milk would be maintained. Mr. R. S. HUDSON answered that dairy cows received priority in the allocation of feeding stuffs under the rationing scheme. Every encouragement was given to dairy farmers in the ploughing-up campaign to become more self-supporting and to safeguard supplies of feed next winter by making silage and growing suitable fodder crops for their herds. In addition the Government recently announced prices for milk during the ensuing twelve months designed to maintain production at the highest level compatible with war conditions.

Medical Publishing and Reserved Occupations.—On March 18 Sir E. GRAHAM-LITTLE asked if the Minister of Labour would give consideration, in revising the Schedule of Reserved Occupations, to the necessity for retaining a sufficient number of employees of firms publishing medical and nursing books, a category in which fresh publications were demanded by the continuous advances in medicine and nursing. Mr. TOMLINSON said that it would not be practicable to place such publishing firms in a special category. If in any case it was regarded as important to retain the services of a particular individual, application for deferment could be made in the usual manner.

Medical News

A Chadwick Public Lecture on "Air Raid Shelters—Design and Construction, with Special Reference to Hygienic Considerations," will be delivered at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., on Tuesday, April 8, at 2.30 p.m., when Dr. S. L. Wright will discuss hygienic considerations and Mr. Phillip O. Reece design and construction.

The sixty-first annual meeting of the Mental After-Care Association will be held in the rooms of the Royal Society at Burlington House, Piccadilly, W.1, on Tuesday, March 25, at 2.45 o'clock, under the presidency of Princess Arthur of Connaught. Among the speakers will be Colonel Henry Yellowlees, M.D., chairman of council. Anyone interested in the work of the association will be welcome.

The annual general meeting of the Central Council for the Care of Cripples will be held at Carnegie House, 117, Piccadilly, London, W., on Friday, March 28, at 2.30 p.m. An address will be given by the Right Hon. Ernest Brown, M.P., Minister of Health.

The next meeting of the Shaftesbury Military Hospital Medical Society will be held at the hospital on Tuesday, March 25, at 2.30 p.m., when there will be a discussion on "The Management of Battle Casualties in the Light of Modern Operational Tactics," to be opened by Colonel C. L. Franklin, A.M.S.

The Ling Physical Education Association (Hamilton House, Bidborough Street, W.C.1) is holding an Easter holiday course at the Bedford Physical Training College from April 15 to 18, when there will be many lectures and discussions on a variety of subjects as well as practical classes in the different branches of physical education. Medical, legal, and social welfare matters are among the subjects on which lectures will be given. Dr. Janet Aitken, senior physician, Elizabeth Garrett Anderson Hospital, is to speak on "Rheumatism in School Children," and Miss P. C. Colson on "The National Organization of Physical Recreation." There will be group discussions on "Problems of Rural Reception Areas," "Medical Inspection and the Gymnast," and other matters interesting to those concerned with education. Within a few days of the publication of the programme all the available places were filled.

The B.B.C. announces that "Health Magazine," a series of topical notes on wartime health—contributed mainly by doctors—will be continued on Fridays during April at 10.45 a.m. Two broadcasts in the daytime programmes for schools deal with medical history. The first, on April 1 at 1.50 p.m., in the series "Our Changing Countryside," tells the story of the village nurse from "Mrs. Gamp" to a public health service. It also describes the aeroplane ambulance in the Highlands. The second talk, on April 24 at 2.40 p.m., in the series "Movements and Men," describes how Elizabeth Garrett Anderson struggled to become a doctor and how she helped to open a path for other women.

No. 8

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended February 22, 1941.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 120 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941					1940 (Corresponding Week)

Rate per 1,000 total births (including stillborn)			42					51		

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

For the week ending February 22, scarlet fever, whooping-cough, cerebrospinal fever, and dysentery all increased in incidence in England and Wales: generally speaking, these diseases were also more prevalent in London, with the exception of scarlet fever and cerebrospinal fever, and in Scotland with the exception of cerebrospinal fever. Since the week ending February 22 notifications have begun to diminish in number: February 22, 434; March 1, 400; March 8, 370; it is hoped that this downward trend will continue. At present fifty out of the total sixty-one administrative areas in the whole country are involved, notably Lancaster 61; Yorks, West Riding, 37; Glamorgan 36; London 21; Warwick 20; Middlesex 19; Essex 17; Chester 15; Gloucester 14; Durham, Southampton, and Stafford 13 each; Kent 12; Derby and Surrey 10 each. In Scotland twenty-three counties or boroughs are affected, chiefly the counties of Lanark 4, and Berwick 3; and the boroughs of Glasgow 21, Edinburgh 6, and Aberdeen and Paisley 3 each.

Dysentery

Dysentery is present in nineteen administrative areas, but over four-fifths of the cases occurred in six areas—namely, Yorks, West Riding, 51 (Bradford 20, Sheffield 12, Wakefield 11, Wortley R.D. 19, Aireborough U.D. 1); Essex 39 (Colchester 34, Brentwood U.D. 5); London 36 (Wandsworth 24, St. Marylebone 4, Chelsea and Finsbury St. Pancras 2 each, Hampstead and Stepney 1 each); Lancaster 25 (Manchester 5, St. Helens 1, Lancaster M.B. 6, Preston R.D. 4, Whiston R.D. 3, Warrington R.D. 2, Prestwich M.B. 1); Dorset 16, in Weymouth and Melcombe Regis M.B.

Influenza

In the week ended March 8, 199 deaths were ascribed to influenza in the 126 great towns—68 fewer than in the previous week. Of these deaths, 6.5% were at ages under 25 and 55.8% at ages over 65. In the County of London the deaths decreased from 20 to 13; the proportion of total deaths coming from the South-Eastern Area was 35.6%. This is the third week of decline in total mortality, and it is highly probable that the winter epidemic has spent its force.

Typhus Fever

Two cases of typhus fever were notified during the week in Clifton R.D., Co. Galway, and reports have since been received that between February 17 and 26, 23 cases of this disease have been admitted to hospital in this locality. Precautions taken to prevent spread appear to have been successful and there have been no deaths.

Registrar-General's Return for Northern Ireland for the Quarter Ended December 31, 1940

During the quarter 5,490 births (2,851 males, 2,639 females) were registered, equivalent to an annual rate of 16.9 per 1,000 of the estimated population, or 1.5 below the average for the corresponding quarters for the preceding five years. Illegitimate births were 4.4% of the total. There were 3,691 deaths (2,077 males, 1,914 females), corresponding to an annual rate of 12.3, or 1.4 below the average rate for 1935-9. Infant mortality was 73 per 1,000 births, compared with 67 for 1940 and an average of 76 for the five preceding years.

Leon J. Aries (*Surgery*, 1941, **9**, 51), as a result of experimental studies with synthetic fibre (nylon) as a buried suture, concludes that nylon has all the good qualities of silk and in addition is stronger and less irritating. It may be boiled several times without losing its original tensile strength. He found that a multifilament nylon was flexible, easily handled, and threaded without difficulty on fine needles. This suture approximated tissues without cutting through, and in fascia and muscle did not cause as much irritation as silk. Experiment on hollow viscera showed the same properties, and the use of nylon in attaching such viscera to the abdominal wall did not result in fistulous tracts.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE No.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES.—EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

How are Road Accident Injuries Caused?

Lieut.-Colonel J. A. A. PICKARD, D.S.O. (general secretary, the Royal Society for the Prevention of Accidents, 52, Grosvenor Gardens, S.W.1), writes: Are road accident injuries mainly due to impact with the vehicle or with the road or by crushing? In factories, injuries due to being struck by reciprocating machinery such as cranks have been lessened by facing such moving parts with sorbo rubber. It has been suggested to us that if the bumpers and wings of motor vehicles were similarly treated the severity of injuries from road accidents would be reduced considerably. I should greatly appreciate the medical view on this point.

Calcium Lactate

Dr. J. A. BROWN (Birmingham) writes: Mr. A. J. Hobson's prescription (February 1, p. 182) becomes "thick and valueless" because it contains excess of $CaCO_3$, resulting in a mixture of calcium lactate and calcium carbonate. The following prescription contains calcium lactate grains xv in each dose, and will remain clear and active for ten to fourteen days:

℞	Calcii carb.	3iij
	Ac. lactic. pur.	3j
	Aq.	ad 3viij

F.M. Sig.: 3ss t.d.s., p.c.

Mix the $CaCO_3$ with two ounces of water in a wide measure; shake well; add lactic acid slowly. The mixture is of great value in the prevention and treatment of chilblains and in the treatment of urticaria. Preventive treatment of chilblains should be commenced in October, 3ss t.d.s. for a week, 3ss bis die subsequently. I have not tried the effect of this treatment for dysmenorrhoea.

Jam from Rose Hips

Dr. MARGARET D. WRIGHT (Hammersmith) writes in reply to Dr. W. J. Burns Selkirk (March 15, p. 426): To every pound of hips allow 1/2 pint of water. Boil till the fruit is tender and pass the pulp through a fine sieve to keep back the seeds. Add 1 lb. of sugar to 1 lb. of pulp and boil till it jellies. No hips should be used for jam until they have been touched by frost. Either an enamel-lined or glass oven-ware saucepan *must* be used.

Treatment of Night Sweats

Dr. MICHAEL G. GOOD writes in reply to "J. N. T." (March 8, p. 389): In a patient suffering from heavy night sweats and slightly raised temperature a tuberculous lesion can be excluded only after an x-ray investigation of the chest and an examination of the sputum, if present, are negative. For the relief of night sweats I recommend barbitone 5 grains taken at bedtime or, alternatively, phenobarbitone 1/2 grain t.d.s.

A Case of Cow-pox

Dr. J. HOWART NIXON (Chippenham) writes: The description given by Dr. McCloy, March 8 (p. 362), suggests to me that though cow-pox is common in man (as Jenner knew), his case may be one of foot-and-mouth disease in the human being. This will be confirmed by an outbreak of foot-and-mouth disease in the cloven hoof animals in the district and disseminated irregularly on various farms. The veterinary profession is not unanimous on the incidence of foot-and-mouth disease in man, though it has been proved by cases quoted by Prof. J. A. Nixon and myself, investigated in Wilts and Somerset, and later confirmed by outbreaks of the disease in the district, to be of more frequent occurrence than suspected, as the older generation of farmers knew and cured. The death rate in cattle is about 2%, but the infectivity is so high that the slaughter policy of the Government is justified. But why not produce a race of cattle immune to foot-and-mouth disease, as can be scientifically done?

Income Tax

Salary and Allowances

"A. B." is working under the E.M.S. scheme and receives a salary of £550 and allowances of £100. Is he liable on the £100?

*** Yes, if it is received in cash, as apparently it is.

Cars Destroyed by Bombs

"H." possessed two cars, A and M, for which running costs and depreciation were allowed. Both were destroyed by one bomb. Another M car was then hired with option to purchase, but this also was hit by a bomb almost at once. The owner accepted as compensation the wrecks of the two M cars. The A car was sold for £5. Since then another A car has been bought for £30. How should these disasters be reflected in the income tax return?

*** The return for 1940–1 will not be affected; the allowances to be claimed in making the return for a subsequent year are as follows. (In so far as the claim ranks as an expense it will affect the profit of the professional year—that is, to December 31—in which the loss occurred.)

(*a*) Obsolescence allowance as an expense incurred when the car was replaced (i) for the first A car—value of the car as written down after deduction of the 1940–1 depreciation allowance less the £5 for which it was sold. The maximum allowance is the £30 expended; (ii) for the first M car the whole of the written-down value should be recorded for future reference: no claim can be made until the car is replaced. (*b*) Depreciation allowance on the second M on its estimated capital value and the second A car on its cost—that is, £30—for the period during which they were used.

LETTERS, NOTES, ETC.

Paratyphoid in Infancy

Dr. F. O. CLARKE (Blackpool) writes: In your issue of March 8 (p. 385) there is a notice of a case of paratyphoid A in a male infant aged 1 year. About eight years ago I had as a patient a female infant under 1 year suffering from paratyphoid B. The infant was artificially fed. In the same house there were two young girls suffering from paratyphoid B, confirmed by agglutination test. In the case of the infant I did not have an agglutination test done, as the symptoms and signs were diagnostic, including a few rose spots. It would be interesting to know if the case of paratyphoid B is also "remarkable owing to the rarity of the disease at that age."

Hay-fever Desensitization

Dr. SINCLAIR MILLER (Harrogate) writes: For several years past I have had an opportunity of observing the benefit derived from an intensive course of a polyvalent grass-pollen vaccine in the prevention of hay-fever attacks. The course of inoculations is usually started in March, the initial dose of the vaccine being dependent on the reaction to a skin sensitization test. The patient is taught to give his own injections, following a technique similar to that used for insulin, and various dilutions of the vaccine are supplied in rubber-capped bottles so that the patient can readily increase each succeeding dose—a 15% increase on the previous dose is the standard accepted. The injections are generally given daily, though occasionally twice daily if the commencement of the course has been delayed. In most cases an end dose of 100,000 units is reached before the last week of May, when injections are stopped. In practically all cases coming under a full course of inoculations there has been complete desensitization to pollen and freedom from hay-fever symptoms for the current year. By the following springtime sensitization has returned, though generally to a less degree, and a further course of inoculations is required.

Cleansing the Shelters

One of the problems connected with public air-raid shelters is that of adequate cleansing. It appears that local authorities have to spend large sums of money, and to use numbers of men who can ill be spared, for this admittedly important work. Experiments have therefore been carried out by the Health and Cleanliness Council (Aldwych House, W.C.2) with an electric floor-cleaning apparatus, capable of washing thoroughly and drying 3,000 superficial feet an hour. The experiments were so successful that it is proposed to put a mobile cleansing unit on the road at an early date. This unit will comprise an electric floor scrubber working from light or power laid on in the shelter or from a generator on the van. It is hoped to include in the service unit electrical sprays for the suppression of vermin, etc.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MARCH 22 1941

ECONOMY OF DRUGS IN WARTIME

MEMORANDUM BY THERAPEUTIC REQUIREMENTS COMMITTEE

Following the statement on shortage of drugs by the Ministry of Health and the Department of Health for Scotland reproduced in the *British Medical Journal* of March 8 (p. 372), the Therapeutic Requirements Committee of the Medical Research Council has issued a memorandum on Economy in the Use of Drugs in Wartime.[1] The membership of the committee is as follows: Prof. L. J. Witts, M.D. (chairman), Prof. A. J. Clark, M.D., Mr. C. E. Corfield, B.Sc., Mr. H. Davis, Ph.D., Prof. J. A. Gunn, M.D., Dr. Philip Hamill, Mr. R. Dawson Hutchinson, M.P.S., Dr. W. P. Kennedy, Mr. A. Mortimer, M.P.S., and Prof. G. H. Wooldridge, F.R.C.V.S., with Dr. C. H. Hampshire as secretary. After recalling the appointment of the committee in September, 1939, the memorandum proceeds:

The following classification of drugs, according to their therapeutic value and availability for use in wartime, has been prepared by the committee. It is based on a provisional list which was circulated in September, 1940, to departments, bodies, and institutions concerned with the supply or use of drugs, and which was also extensively quoted in various journals. Certain supplementary lists of a more specialized character were subsequently issued in a similar limited way. The present list has been revised and extended in accordance with suggestions received as a result of this preliminary action.

If a list of drugs were to be restricted to those that are essential for the saving of life it would indeed be small; but the committee does not feel that there is at present any necessity for so drastic a reduction. The position when the committee first met was that most drugs which came from abroad were being imported into this country under open general licences, and something like a vicious circle had developed. Because there was no shortage drugs which were not essential continued to be used, and, as they were used, further supplies were imported. Moreover, important drugs were used for purposes for which they were not essential. It now appears probable that, in order to conserve our foreign exchange resources and relieve the strain imposed on our shipping and port facilities, such imports will have to be restricted to the minimum which is really necessary in respect of the population at home and for the export trade. It is in these circumstances that the committee has prepared this revised classification of drugs for the assistance of Government Departments and of the various bodies concerned with the preparation of formularies or with the manufacture and distribution of drugs, both for human and veterinary use, and for the information and guidance of medical and veterinary practitioners.

The list is based on the *British Pharmacopoeia, 1932*, including Addenda 1936 and 1940, and on the *British Pharmaceutical Codex*, 1934. Preparations composed of drugs mentioned in the list are not usually included, nor are all the alkaloids or active principles which may be derived from crude drugs imported into this country separately listed. As there is no *British veterinary pharmacopoeia*, and therefore no official list of sera and vaccines for veterinary use, the committee has not included veterinary sera and vaccines, but prescribers are assured that substances of this class which are of proved efficacy will be freely available. Proprietary names of drugs are not used except where it has seemed unavoidable, and although this has meant the omission of certain valuable proprietary preparations which are manufactured in this country, it is hoped that no essential drug has been left out of the list. In wartime it is more than ever desirable to order drugs by non-proprietary names, otherwise a false impression of scarcity may be created by the disappearance of a particular brand from the market. Multiple names are very common amongst the arsenicals, barbiturates, local anaesthetics, and mercurials, and variations may be performed on a familiar chemical theme to produce branded articles differing only slightly from one another. Prescribers who do not recognize a particular drug under the nomenclature used in this list are therefore advised to consult the schedule of Pharmaceutical Specialities, British Equivalents and Alternatives for Foreign Proprietary Products, 2nd Edition, 1940, published by the Association of British Chemical Manufacturers. They will probably discover from the schedule that the drug has a non-proprietary synonym, and that this is the name used in the present list, or else that an equivalent is manufactured in Great Britain.

Economy in the use of a drug may be necessary in wartime because the drug is imported or because its manufacture at home diverts materials and skill from other essential services. It is well known that the majority of the vegetable drugs in the *British Pharmacopoeia* comes from over-seas, but it is not so generally realized that an important proportion of the newer synthetic drugs, or of the raw materials from which they are made, is also imported. It would not be politic at the present time to indicate which drugs are in whole or in major part derived from imported sources. It must be emphasized, however, that the fact that a drug could be synthesized from materials obtainable in this country does not indicate that this has been the custom in the past or that it would be practicable now.

The drugs in the list are classified as follows: (A) Drugs which are at present either (1) regarded as essential, or (2) readily available. (B) Drugs which are essential for certain purposes but not for others, and in the use of which strict economy should be observed. (C) Drugs which are not essential and do not justify importation or manufacture for home use in wartime. Drugs marked * are specially called for under Acts and Orders of the Ministry of Agriculture.

It is not always possible to follow a logical sequence in classification owing to the frequency of special cases. When several imported drugs have a similar action, one which comes from a sterling area and appears easiest of shipment has usually been chosen for group (A), and the others have been classified (C). Essential drugs have been classified (B) when they are already in short supply or are expected soon to be so, or when they are subject to special Government controls. In such cases prescribers must exercise rigid economy so that a sufficiency of the drugs may be conserved for the purposes for which they are most valuable. No drug which could strictly be described as essential has been placed in category (C), but it must be realized that, owing to shortage of supplies, a few drugs which are deservedly popular have had to be classified in this way. Where drugs have been marked non-essential (C), or restriction has been advised (B), substitutes procurable in this country have been indicated in most cases. In conclusion, the committee wishes to make it clear that this list is primarily intended to secure the wisest economy in drugs for consumption in this country, and that other considerations may affect the importa-

tion or manufacture of drugs for the export trade. [To facilitate reference the complete list has been regrouped into the committee's categories.]

A.—Drugs which are at present either regarded as essential or are readily available

Drug	Substitute or Equivalent and Remarks
Acacia	
Acetarsol	
Acidum Acetylsalicylicum	
Acidum Ascorbicum	
Acidum Chromicum (Chromii Trioxidum)	
Acidum Hydrochloricum	
Acidum Hydrocyanicum	
Acidum Mandelicum	
Acidum Nicotinicum	
Acidum Phosphoricum	
Acidum Salicylicum	
Acidum Sulphuricum	
Acidum Tannicum	
Acriflavina	
Adeps Lanae	Under Government control.
Adrenalina, its salts and esters	
Aether	
Aethylis Chloridum	
Aethylmorphinae Hydrochloridum	
Allobarbitonum	
Aloe	
Aloinum	
Alumen	Use ammonium alum only.
Aluminii Acetas	Not to be made from potassium alum.
Aluminii Hydroxidum	Not to be made from potassium alum.
Aminophyllina	See Theophyllina cum Aethylenediamina.
Ammonii Carbonas	
Ammonii Chloridum	
Ammonii Phosphas Acidus	
Amphetamina	
Amylis Nitris	
Amylocainae Hydrochloridum	
Anethum	Production in the United Kingdom should be encouraged.
Aneurinae Hydrochloridum	
Aniline Dyes	These include Bordeaux B, brilliant green, crystal violet, fuchsine, gentian violet, malachite green, methyl violet, and scarlet red.
Anisum	
Antimony Compounds	
Apomorphinae Hydrochloridum	
Areca	
Arecolinae Hydrobromidum	
Argenti Nitras	
Argentoproteinum	
Arseni Trioxidum*	
Atropina and its salts	
Atropinae Methylnitras	
Balsamum Peruvianum	
Barbitonum	
Barbitonum Solubile	
Bario Sulphas	
Belladonnae Folium	
Belladonnae Radix	
Benzocaina	
Benzoinum	Production within the Empire should be encouraged.
Benzylis Benzoas	
Betanaphthol	
Bismuthum Praecipitatum	
Bromethol	
Calamina	
Calciferol	
Calcii Carbonas	
Calcii Chloridum	
Calcii Gluconas	
Calcii Hydroxidum	
Calcii Lactas	
Calcii Sulphas Exsiccatus	
Calx Chlorinata*	
Camphora	Production within the Empire should be encouraged.
Carbacholum	
Carbamide (Urea)	
Carbo	
Carbo Activatus	
Carbonei Dioxidum	
Carbonei Tetrachloridum	
Cardamomum	
Catechu	
Cera	
Chimofonum	
Chloralis Hydras	
Chloramina	
Chlorbutol	
Chlorinated Xylenol	*Para*chloro*meta*xylenol.
Chlorocresol	*Para*chloro*meta*cresol.
Chloroformum	
Chondrus	Production in the United Kingdom should be encouraged.
Chromii Trioxidum (Acidum Chromicum)	
Cocae Folium	
Cocainae Hydrochloridum	
Codeina	Production within the Empire should be encouraged.
Codeina and its salts	
Codeina Phosphas	
Colchici Cormus	Production in the United Kingdom should be encouraged.
Colchici Semen	
Colophonium	
Creosotum	Production within the Empire should be encouraged.
Cresol	
Creta	
Cupri Sulphas	
Derris*	
Diamorphinae Hydrochloridum	
Digitalis	
Digoxinum	
Diodone	
Dithranol	Dioxyanthranol.
Emetina and its salts	See Ipecacuanha.
Ephedra	Production within the Empire should be encouraged.
Ephedrina and its salts	
Ergot Alkaloids	
Ergota	Production within the Empire should be encouraged.
Extractum Fellis Bovini	
Extractum Pituitarii Liquidum (and preparations for intranasal insufflation)	
Extractum Suprarenali Corticis	
Extractum Thyroidei Liquidum	
Ferri Carbonas	
Ferri Perchloridum	
Ferri Sulphas	
Ferrum Redactum	
Fluoresceinum Solubile	
Gelatinum	
Glycerylis Trinitras	
Gold Compounds	
Guaiacol	
Heparin	
Hexobarbitonum	
Hexobarbitonum Solubile	
Hexamina	
Hexylresorcinol	
Histaminae Phosphas Acidus	
Homatropina and its salts	
Hyoscyamus muticus	For manufacture of atropine. Production within the Empire should be encouraged.
Hyoscyamus niger	Production in the United Kingdom should be encouraged.
Hyoscina and its salts	
Indicarminum	
Insulinum	
Insulinum Protaminatum cum Zinco	
Iodoformum	
Iodophthaleinum	
Iodoxylum	
Ispaghula	
Kaolinum	
Kino	
Lead salts	
Leptazolum	
Liquor Calcis Sulphuratae	
Liquor Cresolis Saponatus	Not to be made with potassium hydroxide.
Liquor Ferri Perchloridi	
Liquor Formaldehydi	
Liquor Glycerylis Trinitratis	
Liquor Hydrogenii Peroxidi	
Liquor Picis Carbonis	
Magnesii Carbonas	
Magnesii Oxidum	
Magnesii Trisilicas	
Menthol	Production within the Empire should be encouraged.
Mepacrinae Hydrochloridum	
Mepacrinae Methanesulphonas	
Mersalylum	
Methylis Salicylas	
Methylthioninae Chloridum	
Morphina and its salts	
Neoarsphenamina	
Nicotinamidum	
Nikethamidum	
Nitrogenii Monoxidum	
Nux Vomica	
Oleum Anethi	Production within the Empire should be encouraged.
Oleum Anisi	
Oleum Cadinum	
Oleum Caryophylli	
Oleum Cinnamomi	See Cinnamomum.
Oleum Eucalypti	
Oleum Hydnocarpi	
Oleum Iodisatum	
Oleum Limonis	Production within the Empire should be encouraged.
Oleum Menthae Piperitae	
Oleum Ricini	
Oleum Terebinthinae	Production within the Empire should be encouraged.
Oleum Theobromatis	
Oleum Vitaminatum	
Opium	
Orthocaina	
Oxygenium	
Pamaquinum	
Panzeatinum	
Papainum	
Paraldehydum	
Pentobarbital Sodium	
Pepsinum	
Phemitonum	
Phenacetinum	
Phenobarbitonum	
Phenobarbitonum Solubile	
Phenol*	
Phenolphthaleinum	
Phenothazine	
Physostigmina and its salts	
Physostigminae Salicylas	

Drug	Substitute or Equivalent and Remarks
Pirevan	
Pix Carbonis Praeparata	
Pix Liquida	
Plumbi Acetas	
Plumbi Monoxidum	
Procainae Hydrochloridum	
Proflavina	
Pyroxylinum	
Quassia	
Quinidinae Sulphas	
Quinine salts	
Resorcinol	
Rheum	Production of *Rheum palmatum* in the Empire should be encouraged.
Saccharinum Solubile	
Scoparium	
Senna	
Sera and Vaccines:	
Antitoxinum Diphthericum	
Antitoxinum Oedematiens	
Antitoxinum Staphylococcicum	
Antitoxinum Streptococcicum	
Antitoxinum Tetanicum	
Antitoxinum Vibriosepticum	
Antitoxinum Welchicum	
Serum Antianthracum	
Serum Antidysentericum (Shiga)	
Serum Antimeningococcicum	
Serum Antipneumococcicum I	
Serum Antipneumococcicum II	
Toxinum Diphthericum Calefactum	
Toxinum Diphthericum Detoxicatum	This includes diphtheria toxoid, diphtheria toxoid antitoxin mixture, diphtheria toxoid antitoxin floccules, and alum-precipitated toxoid.
Toxinum Diphthericum Diagnosticum	
Toxinum Staphylococcicum	
Toxinum Streptococcicum Diagnosticum (Scarlatina)	
Toxinum Tetanicum Detoxicatum	
Tuberculinum Pristinum	
Vaccinum Chloreticum	
Vaccinum Pertussis	
Vaccinum Pestis	
Vaccinum Staphylococcicum	
Vaccinum Typho-paratyphosum	
Sinapis	
Soaps	Potash should not be used in the manufacture of soaps.
Soda Lime	
Sodii Aminarsonas	
Sodii Bicarbonas	
Sodii Carbonas*	
Sodii Chloridum	
Sodii Diphenylhydantoinas (Dilantinum Solubile)	
Sodii Iodidum	
Sodii Nitris	
Sodii Phosphas	
Sodii Phosphas Acidus	
Sodii Salicylas	
Sodii Sulphas	
Sodii Thiosulphas	
Stannum	
Stanni Oxidum	
Stibophenum	
Stilboestrol	
Stramonium	Production in the U.K. should be encouraged.
Strychnina and its salts	
Sulphanilamidum	
Sulphapyridinum	
Sulpharsphenamina	
Sulphathiazole	
Sulphur*	
Suraminum	
Theobromina	
Theobromina et Sodii Salicylas	
Theophyllina	
Theophyllina cum Aethylenediamina	
Thymol	Production within the Empire should be encouraged.
Thyroideum	
Thyroxinsodium	
Totaquina	
Tragacantha	Production within the Empire should be encouraged. Methyl cellulose and similar synthetics may be tried as substitutes.
Trinitrophenol	
Tryparsamidum	
Urea	
Ventriculus Desiccatus	
Vitaminis	See Acidum Ascorbicum, Aneurinae Hydrochloridum, Calciferol, Liquor Vitamini A Concentratus, Liquor Vitaminis D Concentratus, Liquor Vitaminorum A et D Concentratus, Acidum Nicotinicum, Oleum Hippoglossi, Oleum Morrhuae, Oleum Vitaminatum.
Zinci Carbonas	
Zinci Oxidum	
Zinci Sulphas	
Zingiber	If the official variety is scarce, supplies from other sources—e.g., Africa,—should be permitted.

B.—Drugs which are essential for certain purposes but not for others, and in the use of which strict economy should be observed

Drug	Substitute or Equivalent and Remarks
Acetonum	Under Government control.
Acidum Aceticum	
Acidum Benzoicum	
Acidum Boricum	Boric acid in Boric Lint is wasted. Reserve for Cataplasma Kaolini and eye lotions. In dermatological practice saline compresses may be used instead of boric fomentations, and for dusting powders boric acid may be replaced by zinc oxide, magnesium trisilicate or kaolin.
Acidum Citricum	Manufacture under Government control.
Acidum Lacticum	
Acidum Nitricum	
Acidum Oleicum	
Acidum Tartaricum and its salts	Raw material is imported. Production within the Empire should be encouraged.
Adeps Benzoinatus	Under Government control.
Agar	Substitute: Ispaghula. Agar should be reserved for bacteriological media. Production within the Empire should be encouraged.
Alcohol	Many tinctures can be replaced by concentrated preparations. Economy is essential.
Amylum	Under Government control. In dermatological practice substitute saline compresses for starch poultices, and for powders see remarks under boric acid.
Aurantii Cortex	Countries of origin: Spain, Sicily, Malta. Production within the Empire should be encouraged. Limited supplies are available from the Empire at present.
Benzaminae *Hydrochloridum*	
Benzaminae Lactas	
Bismuth salts	Reserve for the treatment of syphilis and tropical diseases. Substitutes (for gastro-intestinal conditions): Aluminium hydroxide, chalk, kaolin, magnesium trisilicate.
Bismuth Salicylas	Reserve for the treatment of syphilis and tropical diseases. Substitutes (for gastro-intestinal conditions): Activated charcoal, kaolin.
Borax	In dermatological practice reserve for Unguentum Aquosum. Glycerin of borax and honey of borax may be replaced by aqueous solutions of aniline dyes in the treatment of thrush.
Bromides	Strict economy is necessary.
Caffeina	Omit from compound tablets such as compound aspirin tablets.
Caffeina et Sodii Benzoas	Amphetamine (benzedrine), leptazol (cardiazol), and nikethamide (coramine) are partial substitutes.
Capsicum	Countries of origin: Nigeria, Sierra Leone, E. India. Restrict use of capsicum to manufacture of capsicum wool. Substitute: Sinapis. Colonial varieties of *capsicum* may be obtainable.
Carbromalum	
Caryophyllum	Countries of origin: E. India, Zanzibar, Pemba, Madagascar. Reserve for distillation of the oil.
Cascara Sagrada	Countries of origin: Canada, U.S.A. Production within the Empire should be encouraged.
Chrysarobinum	Production within the Empire should be encouraged. Substitute: Dithranol.
Cinchona	Importation should be restricted to supplies required for the manufacture of quinine. The use of cinchona as a bitter should be discouraged. Production within the Empire should be encouraged.
Corpus Luteum and its preparations	
Cyclopropanum	
Desoxycorticosterone and its esters	Extract of suprarenal cortex is in freer supply.
Dextrosum	Under Government control. Reserve for injection.
Dextrosum Monohydratum	Under Government control. Strict economy is essential.
Extractum Hepatis Liquidum (and preparations of the *active principles of liver*)	Importation of liver is under Government control. Injection therapy is more economical and effective than administration by mouth. Desiccated stomach may be substituted for oral administration.
Extractum Malti	Under Government control.
Extractum Parathyroidei (and parathyroid preparations for parenteral injection)	
Ferri Carbonas Saccharatus	Restrict to children.
Ferri et Ammonii Citras	Not the most economical form of iron: ferrous sulphate is cheaper.
Ferri Lactas	
Ferri Subchloridum Citratum	Not the most economical form of iron; ferrous sulphate is cheaper.
Filix Mas	Reserve for use when other anthelmintics are contraindicated. Production in the United Kingdom should be encouraged.
Galla	
Glucosum	Under Government control. Strict economy is essential.
Glycerinum	Substitutes are under investigation.
Glycyrrhiza	Countries of origin: Spain, Sicily, Italy, Iraq, U.S.S.R. Production within the Empire should be encouraged.
Hydrargyrum	
Hydrargyrum Ammoniatum	
Hydrargyri Iodidum Rubrum	

Drug	Substitute or Equivalent and Remarks
Hydrargyri Oxidum Flavum	
Hydrargyri Oxycyanidum	
Hydrargyri Perchloridum	Substitute: A phenolic antiseptic of the chlorinated phenol type.
Hydrargyri Subchloridum	
Ichthammol	
Injectio Hepatis	
Iodum	Production at home and within the Empire should be encouraged. Adequate supplies are available, but, owing to shortage of alcohol, the use of alcoholic solutions of iodine must be restricted. Substitutes: [illegible] ine, acriflavine [illegible] olet, proflavine
Ipecacuanha	Galenical preparations, expectorants and emetics are not essential and the crude drug should preferably be reserved for the manufacture of emetine. Production within the Empire should be encouraged.
Jaborandi	Reserve for the manufacture of pilocarpine. Production within the Empire should be encouraged.
Jalapa / Jalapae Resina	Reserve for veterinary use. Countries of origin: Mexico, India. Substitute: Colocynth.
Lactosum	
Laevulosum	
Liquor Vitamini A Concentratus	
Liquor Vitamini D Concentratus	
Liquor Vitaminorum A et D Concentratus	
Magnesii Chloridum	Reserve for veterinary use.
Mel	Under Government control.
Oestradiol, Oestriol, Oestrone and their esters	
Oleum Arachis	
Oleum Chenopodii	In Great Britain reserve for veterinary use. Substitutes: Carbon tetrachloride, thymol. Production within the Empire should be encouraged.
Oleum Gossypii Seminis	
Oleum Hippoglossi	
Oleum Lini	Under Government control. Reserve for internal use in veterinary practice.
Oleum Morrhuae	Under Government control. Substitute Oleum Vitaminatum and veterinary vitaminized oils, as applicable, to relieve scarcity.
Oleum Olivae	Under Government control. Arachis and other suitable vegetable oils are recognized as substitutes in official preparations.
Oleum Rapae	Reserve for external use in veterinary practice.
Oleum Sesami	See under Oleum Amygdalae.
Paraffinum Liquidum	Under Government control. Its use should be discouraged.
Paraffinum Molle	Under Government control.
Parathyroideum	
Pilocarpina and its salts	Substitute: Physostigmine and its salts for most purposes.
Pituitarium	Including anterior lobe extracts.
Podophylli Resina	Restrict to Indian Podophyllum.
Potassii Tartras Acidus	See under Acidum Tartaricum.
Prolactin	
Quillaia	Countries of origin: Chile, Peru, India.
Santoninum	Countries of origin: U.S.S.R., Kashmir. Importation difficult. Production within the Empire should be encouraged. Substitutes: Hexylresorcinol, phenothiazine.
Sodii Benzoas	
Sodii Bromidum	
Sodii Citras	See under Acidum Citricum.
Sodii Lactas	Reserve for use as a glycerin substitute.
Sodii et Potassii Tartras	See under Acidum Tartaricum.
Spiritus Aetheris Nitrosi	Substitute: Concentrated solution of ethyl nitrite.
Spiritus Methylatus Industrialis	Under Government control.
Styrax	Country of origin: Asiatic Turkey. Production within the Empire should be encouraged. Wanted for compound tincture of benzoin.
Sucrosum	Under Government control.
Syrupi	The use of all syrups should be discouraged.
Syrupus Ferri Phosphatis Compositus	Reserve for children.
Tinctures	Many tinctures can be replaced by concentrated preparations. Economy is essential.
Urginea	Importation difficult in wartime.
Valeriana	Production in the United Kingdom should be encouraged.
Vitamins	See Acidum Ascorbicum, Aneurinae Hydrochloridum, Calciferol, Liquor Vitamini A Concentratus, Liquor Vitamini D Concentratus, Liquor Vitaminorum A et D Concentratus, Acidum Nicotinicum, Oleum Hippoglossi, Oleum Morrhuae, Oleum Vitaminatum.
Zinci Chloridum	
Zinci Oleostearas	

C.—Drugs which are not essential and do not justify importation or manufacture for home use in wartime

Drug	Substitute or Equivalent and Remarks
Acetylsalicylicum Acidum	Substitutes: Acetylsalicylic acid or phenacetin.
Acidum Glycerophosphoricum and its salts	No substitute necessary
Acidum Hydrobromicum Dilutum	
Aconitum	Countries of origin: Germany, Switzerland, France. Importation unnecessary. Substitute: Benzocaine for local application.
Aethylenum	
Alcohol Isopropylicus	
Amidopyrina	Substitutes: Acetylsalicylic acid, phenacetin.
Balsamum Tolutanum	Countries of origin: Colombia, S. America. Importation unnecessary in wartime. Production within the Empire should be encouraged.
Betainae Hydrochloridum	
Bromoformum	
Buchu	Country of origin: S. Africa. Importation is unnecessary. Substitutes: Hexamine, mandelic acid, scoparium, sulphanilamide.
Calumba	Country of origin: E. Africa (Mozambique). Production within the Empire should be encouraged. Substitute: Quassia.
Cannabis Indica	Countries of origin: India, S. Africa, Zanzibar.
Cantharis / Cantharidinum	Countries of origin: U.S.S.R., Spain, Hungary, China. Importation unnecessary in wartime. Production within the Empire should be encouraged. Substitute: Sinapis.
Carum	Countries of origin: Holland, Germany. Some English caraway is available and its production should be encouraged. Substitute: Anethum (dill).
Cassia	Country of origin: China. Importation unnecessary.
Coccus	Country of origin: Canary Islands. Importation is unnecessary. Substitute: Solution of Bordeaux B. Other good colours are available.
Copaiba	Country of origin: Northern S. America. Importation unnecessary. Substitutes: Hexamine, mandelic acid, scoparium, sulphanilamide.
Coriandrum	Countries of origin: Morocco, U.S.S.R., India, Central Europe. Importation unnecessary. Substitute: Cardamomum.
Cubeba	Country of origin: Malay Archipelago. Importation unnecessary. Substitutes: Hexamine, mandelic acid, scoparium, sulphanilamide.
Cusso	Country of origin: N.E. Africa. Importation unnecessary. Substitutes: Carbon tetrachloride, male fern.
Erythritylis Tetranitras Dilutus	
Ferri Arsenas	Substitute: Ferrous sulphate with arsenic.
Ferri et Manganii Citras	Substitute: Ferrous sulphate.
Ferri et Quininae Citras	Substitute: Ferrous sulphate.
Ferri et Potassii Tartras	Substitute: Ferrous sulphate.
Ferri et Strychninae Citras	Substitute: Ferrous sulphate with strychnine.
Ferri Glycerophosphis	Substitute: Ferrous sulphate.
Ferri Hypophosphis	Substitute: Ferrous sulphate.
Ficus	Therapeutic value doubtful.
Foeniculum	Production in the United Kingdom should be encouraged.
Gelsemium	Country of origin: U.S.A. Importation unnecessary. Substitutes: Synthetic analgesics.
Gentiana	Countries of origin: France, Germany, Spain. Almost unobtainable. Substitute: Quassia. Production within the Empire should be encouraged.
Hamamelis	Country of origin: U.S.A. Production within the Empire should be encouraged. Substitute: Tannic acid.
Injectio Ferri	Substitute: Ferrous sulphate by mouth.
Krameria	Country of origin: Peru. Production within the Empire should be encouraged. Substitute: Tannic acid.
Linum	Substitute: Cataplasma Kaolini for poultices.
Lobelia	Country of origin: Eastern U.S.A. Production within the Empire should be encouraged. Substitute: Stramonium.
Lobelina	Substitutes: Nikethamide, lepturol.
Magnesii Sulphas	Substitute: Sodium sulphate, of which very large supplies are available.
Methylsulphonal	
Oleum Abietis	Country of origin: North-east U.S.S.R. Importation unnecessary. Substitute: Any oil of pine.
Oleum Amygdalae	Production within the Empire should be encouraged. All vegetable oils and fats are under Government control. Arachis or other vegetable oils may be used if available.
Oleum Camphorae Rectificatum	Substitute: Oleum Terebinthinae. See Camphora.
Oleum Cardamomi	Unnecessary.
Oleum Cari	See Carum.
Oleum Crotonis	Unnecessary.
Oleum Gaultheriae	Substitute: Methyl salicylate.
Oleum Santali	Country of origin: India. Importation unnecessary. Substitutes: Hexamine, mandelic acid, scoparium, sulphanilamide.
Pelletierinae Tannas	Countries of origin: Mediterranean countries. Importation unnecessary. Substitutes: Carbon tetrachloride, male fern.
Phenazonum	Substitutes: Acetylsalicylic acid, phenacetin.
Potassa Sulphurata	Substitutes: Sulphur ointment, solution of sulphurated lime.
Potassii Bicarbonas	Substitute: Sodium bicarbonate.
Potassii Bromidum	Substitute: Sodium bromide.
Potassii Chloras	Not essential.
Potassii Citras	Substitute: Sodium citrate.
Potassii Hydroxidum	Substitute: Sodium hydroxide.
Potassii Iodidum	Substitute: Sodium iodide.
Potassii Nitras	Not essential.
Potassii Permanganas	Substitutes: Solutions of other permanganates, other antiseptics.
Psyllium	Countries of origin: Mediterranean countries. Production within the Empire should be encouraged. Substitute: Ispaghula.
Salicinum	Substitute: Sodium salicylate.
Salol	Unnecessary.

Drug	Substitute or Equivalent and Remarks
Scammonium	Unnecessary. Substitute: Indian podophyllum.
Scilla	Country of origin: Sicily. Production within the Empire should be encouraged. Substitutes: Urginea (Indian squill) and other expectorants.
Senega	Countries of origin: Canada and U.S.A. Importation unnecessary. *Substitutes.* Ammonium carbonate, ammonium bicarbonate, ammonium chloride.
Sodii Tauroglycocholas	Substitute: Extract of ox bile.
Sparteina	
Strophanthus	Countries of origin: Mozambique, Nyasaland. Importation unnecessary. Substitute: Digitalis.
Sulphonal	
Syrupus Ferri Phosphatis cum Quinina et Strychnina	Substitute: Tablets of Easton's syrup.
Talcum Purificatum	Raw material imported. For substitutes see under Acidum Boricum.
Tamarindus	Countries of origin: India, Burma, W. Indies. Importation unnecessary.
Taraxacum	Importation unnecessary in wartime. Production in the United Kingdom should be encouraged.

List of Equivalents

Acaprin	Pirevan is identical.
Anaesthesin	
Atebrin	
Atophan	
Atoxyl	Sodii Aminarsonas is identical.
Averin	Bromethol is identical.
Bayer 205	Suraminum is identical.
Benzedrine	Amphetamina is identical.

EMPLOYMENT OF ALIEN DOCTORS IN HOSPITALS

The following modifications in the restrictions placed on the employment of doctors of enemy nationality in hospitals and similar institutions are announced by the Ministry of Health in a circular (No. 2312) just issued to local and hospital authorities. The modifications are being made in view of the shortage of doctors; the restrictions at present in force affecting other staff (including nurses) as set out in Circulars 2080 and 2193 issued on July 3 and November 4 last will continue to apply.

Doctors of German, Austrian, or Italian nationality qualified to practise in this country either under the ordinary law or under the special provisions of the Medical Practitioners (Temporary Registration) Order, 1941, or selected for employment with a view to registration under the latter provisions, may now be employed in any hospital (whether or not in a protected area), which may provide treatment for members of His Majesty's Forces subject to the following conditions:

(*a*) The employment of such aliens must be on the understanding that, in the event of invasion or other serious military situation which would make it necessary for the military authorities to take full control of the area, the military authorities may find it necessary to order the immediate removal from the hospital of the persons in question.

(*b*) Wherever practicable such aliens should be employed only in wards where British doctors and nurses are also engaged.

(*c*) The number of such alien doctors employed in any hospital must not exceed the following proportions of the total medical staff employed there: hospitals with less than 100 beds, 20%; hospitals with 100 beds or over, 10%.

Condition (c) of Circular 2193 is now modified in its application to doctors of enemy alien nationality to the extent that they may be employed in separate wards set apart for Service patients, subject to the conditions laid down in the previous paragraph.

In any case, an individual permit from the Aliens War Service Department will still be required before an alien can be employed in a hospital which may provide treatment for Service patients. In ordinary circumstances such a permit is not likely to be refused unless it is found that there is reason to think that the applicant might be a danger to national security, but there may be a few exceptional localities from which it may be necessary to continue to exclude persons of enemy alien nationality for reasons of defence.

SCHEME OF CO-ORDINATION FOR HACKNEY'S MEDICAL SERVICES

We have received the following details of a scheme for co-ordinating Hackney's war medical services. The authors, Drs. A. Phillips, P. J. Murnane, M. B. Jay, and C. K. David, state that it is the outcome of discussions by local practitioners, who were much dissatisfied with the borough's war medical services, and felt that no effort was being made to enlist the majority of doctors who were eager to participate in the war effort. It is understood that the scheme is being submitted to the local and central authorities for approval.

The Scheme

The main principle of the scheme is the centralization of the war medical services at the present first-aid posts, all the medical services to be carried out by a rota of doctors working from the posts. At present we have shelter work, rest centres, first-aid posts, and mobile units; this list will probably be increased as the war proceeds. There is no co-ordination between the various medical services. Under this scheme all the services and any additional ones will operate from the first-aid posts. The advantages are:

1. The F.A.Ps are so situated that practically every area in the borough is not more than half a mile from a post. Thus the borough is, for this scheme, divided into five areas.

2. When any medical service is required there will be only one point in each area to which the public, shelter marshals, wardens, fire service, or police should apply for medical aid.

3. A rota of doctors will serve at these points. In this way all the doctors willing to serve will be available, and the work will be fairly distributed.

4. If at any time the work of any branch of the service is suddenly increased this can be easily met, or if all the work is decreased or diminished the necessary adjustments can be easily made.

5. Finally, all the fees accruing from these appointments will be divided among the doctors working the scheme.

We have thus a system which is elastic and allows for eventuality. It will provide a better and more uniform ser for the public, and will obviate the need for making appointments every time there is a change in enemy tac At each F.A.P. there will be a rota of doctors who wish serve and who live within the area served by the post: estimate that there should be about ten doctors attached each post.

The duties will be as follows:

1. Two doctors will be on duty for twenty-four hours and at the F.A.P. during the hours of black-out. One of these doc will visit the larger shelters in the vicinity at night and will st by for them; the other doctor will stand by for any emerge calls at the smaller shelters. The work will be so arranged t the post is never left without a doctor at night.

2. During the day both these doctors will be on call for usual F.A.P. duties. The doctor doing the "larger shelter" dut that night will notify the post of his whereabouts as soon as alert is sounded.

3. One doctor of each rota will be elected to be directly respo sible to the M.O.H. for the special duties of the F.A.P. (preferer being given to the present holders of the post), such as the traini of personnel and working the rota. He will receive an additio fee for the extra responsibility this entails.

4. The rest centres in the same vicinity will be visited during t day by the doctor doing duty at the smaller shelters.

There will be a separate rota for the mobile unit. These men w be responsible for the units and will have no other duties. Prefe ence will be given to the present holders of this appointment if th so wish.

The financial arrangements of this scheme are based on t present rates of pay for the various duties. All these sums a to be pooled. The doctors responsible for the F.A.Ps to th M.O.H. will receive an additional £75 a year. The remainin sum will be divided equally among the doctors on the rota. We estimate that at the present rate of pay, and allowing for rota of ten doctors per post, each doctor will receive abou £200 p.a.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE, 1, Wimpole Street, W.—*Brompton Hospital*, S.W. Mon. and Thurs., 4.45 p.m., M.R.C.P. Course in Chest Diseases. *West End Hospital for Nervous Diseases*. Tues. and Fri., 3.30 p.m., Clinical Demonstrations in Neurology. *Royal National Orthopaedic Hospital*, Stanmore. Sat., 2.15 p.m., F.R.C.S. Clinical Orthopaedic Course. *Medical Society of London*, 11, Chandos Street, W. Wed., 2.30 p.m., Final F.R.C.S. Theoretical Orthopaedics.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Medicine.—Tues., 2 p.m. Discussion: Dyspepsia in the Forces. Openers, Col. H. L. Tidy, Dr. Charles E. Newman, and Major J. G. Scadding.

Section of Psychiatry.—Tues., 2.30 p.m. Paper by Dr. Aubrey Lewis: Psychiatric Aspects of Effort Syndrome. A discussion, to be opened by Dr. W. H. Gillespie, will follow.

Section of Urology.—Thurs., 4.30 p.m. Discussion: Personal Experience of Injuries to the Genito-urinary Tract. Opener, Mr. G. E. Nelson.

Section of Epidemiology and State Medicine.—Fri., 2.30 p.m. Paper by Surgeon Rear-Admiral S. F. Dudley and Surgeon Commander W. G. C. Fitzpatrick: Epidemiology of Pulmonary Tuberculosis in the Royal Navy, especially as regards the Use of Miniature Radiography in its Elucidation. Members of the Clinical, Medicine, and United Services Sections are specially invited to attend the meeting.

DAVYHULME MILITARY HOSPITAL MEDICAL SOCIETY.—*Thurs.*, 3 p.m. Discussion: Deformities of the Hands and Feet. To be opened by Prof. Harry Platt. Medical men and women in any Services (including civilian) will be welcomed.

Branch and Division Meetings to be Held

GLASGOW AND WEST OF SCOTLAND BRANCH.—At 39, Limbank, Crescent, Glasgow, Sunday, March 23, 3 p.m., Drs. J. Nairn Hay and G. L. Pallen, "Recent Developments in the Diagnosis and Treatment of War Gas Casualties." All practitioners in the area of the Branch are invited to attend.

NORTH OF ENGLAND BRANCH.—At Newcastle-upon-Tyne, Thursday, March 27, 2.30 p.m. Lord Horder, "Air raid Shelters and Health"; 3.45 p.m., Drs. J. C. Spence, T. H. Boon, George Davison, and G. A. Smart, Clinical demonstrations. Members of the Services stationed in the area of the Branch are invited to attend.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 5s. 6d. The amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

BIRTHS

MACLEOD.—At Viewfield, Selkirk, on March 4, to Nancy (née Scott), wife of Captain William Macleod, R.A.M.C., a son.

YOUNG.—At Norwood Nursing Home, Glasgow, on March 16, 1941, to Dr. and Mrs. A. Kenneth Young (Mary Lewis), Cathcart View, Paisley Road, Ironshore, a son.

DEATH

BEAN.—On the 11th inst., at 36, Hollybush Road, Hindhead, Surrey, Alexander D. Hall's Burn, M.D.(Edin.), aged 73 years. Funeral, Cremation, Woking, on Thursday, March 13, at 3 p.m. No flowers by request.

BRITISH MEDICAL JOURNAL

USE OF A GLYCERIN–SULPHONAMIDE PASTE ("EUGLAMIDE") IN TREATMENT OF BURNS

BY

J. M. ROBSON, M.D., D.Sc.

Lecturer in Pharmacology, University of Edinburgh

AND

A. B. WALLACE, M.B., F.R.C.S., M.Sc.McGill

Surgeon, Scottish Emergency Medical Service; Assistant, Department of Surgery, University of Edinburgh

(From the Departments of Pharmacology and Surgery, University of Edinburgh)

Since the introduction of the tannic acid technique much progress has been made in the treatment of burns, though there have always been difficulties that have been only partially overcome. The limitations in our present knowledge have, however, been emphasized by the unusual conditions prevailing during the war. In civil life the lesions were mainly scalds and therefore of second degree, except in parts becoming septic, when lesions of the third degree developed.* In war the proportion of burns of the third degree is relatively high, and the problem of dealing with these lesions and their sequels has become much more important.

General Principles

The principles governing the treatment of burns are generally established. Thus it is recognized that the first aim is to save life, the second to avoid infection, and the third to prevent deformity. If life is endangered the consideration of paramount importance is the prevention of secondary shock. This is done by maintaining the body temperature and by the administration of a sedative and of intravenous plasma or serum; then, as soon as is practicable, the burnt area is cleansed and tanned.

In many cases already seen in the present war life has not been endangered, and yet the treatment has not been successful in preventing sepsis and deformity. These unfortunate results have been due essentially to the indiscriminate or faulty use of coagulating agents without consideration of the depth and site of the injury. In the case of third-degree burns there is total destruction of skin, and this lost skin has to be replaced by grafting, whatever the preliminary line of treatment adopted. The ideal mode of treatment is therefore one which as rapidly as possible will give a clean surface suitable for grafting. Up till now tanning has been the method of choice, but it has invariably resulted in infection. Under these conditions the tan separates slowly, leaving an unhealthy granulating surface. It is therefore obvious that this way of dealing with third-degree burns is unsatisfactory, and that there is an urgent need for a more efficient procedure.

The treatment of burns of the face and hands has presented special difficulties. In so far as the face is concerned the problem is mainly that of the third-degree burn, which, even when small, is apt to produce disfigurement on healing. The treatment of second-degree burns of the face should present no special difficulties: there is no complete destruction of the skin, and therefore the use of coagulating agents should give satisfactory results. Nevertheless a number of workers who have used tanning agents have experienced difficulties in such cases.

The greatest problem, however, and one of urgent interest, is the treatment of burns of the hands. The present method of treatment in such cases is by no means satisfactory, and this applies not only to third-degree burns but even to lesions of the second degree. Those who have seen the unfortunate results of the indiscriminate application of tannic acid to burns of the hands will be convinced that the general use of coagulating agents should not be advocated; oedema and sepsis under a rigid tan, together with prolonged immobilization, have played their part in producing limitation of movement, contracture, and, in extreme cases, ischaemic necrosis.

The New Method

The method of treatment described below was evolved for the purpose of meeting these very obvious difficulties. In principle it consists in the application to the burnt area of a water-soluble sulphonamide in solution in glycerin. The sulphonamide compound albucid soluble was chosen because it was freely soluble in water, formed a neutral solution, and was known to be innocuous to tissues. It appears probable that other sulphonamide compounds which possess the qualities mentioned above would be equally effective, but limitations of time and clinical material have so far prevented the carrying out of comparative tests of different compounds.

Glycerin by itself is unsuitable for local application to the surface of the body. The albucid solution was therefore converted into a paste by the addition of a suitable quantity of kaolin. Since the paste contains a glycerin–kaolin mixture it produces the effects usually associated with cataplasma kaolin. Thus there is an increase in the flow of lymph containing antibodies and white blood corpuscles; this will tend to increase the local defence mechanism. The flow of tissue fluids together with the absorption of water by the glycerin helps to reduce the oedema, which is an undesirable feature of burns in certain localities. Preliminary observations showed that the paste tended to dry in the centre of the area of application, consequently a small quantity of cod-liver oil was incorporated. Incidentally, it is possible that this may have additional advantages—e.g., a beneficial effect on tissue repair and a local soothing action.

* In a first-degree burn there is erythema of the affected part: in a second-degree burn partial destruction of skin with or without vesication: and in a third-degree burn total destruction of skin.

Such a paste can be of value only if it does not cause any irritation. It has been found in practice that, though there may be slight pain when it is first applied to the injured area, this very rapidly passes off and does not recur. On the contrary, our experience suggests that in some cases the paste possesses an appreciable soothing effect.

The treatment of burns with this paste allows of early movement. This is of considerable importance, since the immobilization of the affected parts associated with the use of coagulating agents is an important factor in preventing the subsequent restoration to normal functional activity.

Method of Preparing the Paste.—5 grammes of soluble albucid powder is mixed with 100 c.cm. of glycerin; the mixture is then heated cautiously until the solid is completely dissolved. This usually takes about thirty minutes, the mixture being stirred from time to time. The heating is then discontinued; while the mixture is still warm 10 c.cm. of cod-liver oil is added, being thoroughly stirred in. This solution is mixed into a quantity of fine kaolin (about 80 grammes) sufficient to yield a smooth paste of the consistence of thick cream. The mixing is done in a mortar, and, later, on a white slab with a spatula, in order to produce a smooth permanent paste.

Clinical Results.—The paste has been used with success in burns of the hand (second and third degrees), the face and scalp (second and third degrees), the buttock (second and third degrees), the penis and scrotum (second degree); in septic burns, following twenty-four hours of wet dressings; and in burns of the second degree not extensive in area.

The value of the paste in certain conditions—e.g., bedsores, carbuncles—is also being investigated, and it is hoped to report on the results at some future date.

Technique of Application

An anaesthetic may be required for cleansing, but this is not essential, except in most children, in whom fear and apprehension are prominent. Before intervention, cultures are made from the surface of the burn and from blister fluid, and these are repeated every second or third day. In second-degree lesions the affected part is cleansed with gauze wrung out of isotonic saline at body temperature. Blisters and loose epidermis are snipped and removed. In third-degree burns the surface is gently washed with warm physiological saline and all foreign material removed.

In applying the paste a thick spread is made on sterile white lint, gauze, or linen; for burns of the face a mask is cut out. Further dressing is applied if necessary, and the whole is covered with wool and bandaged. In burns affecting the face and in the region of flexures the paste and dressings are reapplied daily, but in other parts they may be kept on for three days before being changed. Where infection is present it is essential, in order to maintain a high local concentration of the sulphonamide, that daily reapplications of the paste be made, no matter the site. At each change of dressing the affected part is wiped clean with wool pledgets soaked in normal saline or cod-liver oil.

Most of the burns treated have been of the second degree, and have occurred in children. In this series neither the interval between the occurrence of the injury and admission to hospital nor the nature of the first-aid treatment appeared to influence the ultimate result. Undoubtedly some regions responded in a very promising manner to the application of the paste—e.g., the hands, the face, the abdomen, the buttocks, the feet, and the penis and scrotum; other areas—e.g., the axilla and shoulder region—showed less response but nevertheless did well. In several patients anaesthesia was not required for preliminary cleansing. Pain was experienced on application of the paste in only a few instances, and irritation was absent. As a rule an early healing surface was obtained, as can be judged from the period during which the patient remained in hospital (see accompanying table).

The rate of healing with the paste (termed "euglamide") compared favourably with that obtained with tannic acid in the two cases in which both methods were used (Nos. 8 and 15). In each of these cases the burn on one hand was treated with silver nitrate while paste was applied to the burn on the other; the hands treated with paste healed and showed normal function before the coagulum on the other hands had begun to separate. In Case 4 (treated originally with charcoal-silver nitrate jelly) the healing properties of the paste when applied to a septic granulating surface compared very favourably with those of acriflavine under the same conditions. Initial sepsis appears to be an indication for the application of euglamide. In such patients the routine adopted up to the present is as follows: hot boric fomentations are applied every four hours for one to two days; a thick spread of the paste is then put on once daily in order to maintain a high local concentration of albucid.

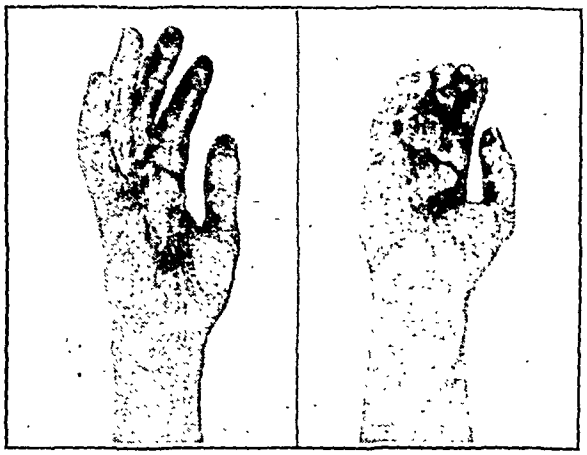
Very satisfactory results were obtained in facial burns. The method of treatment in such cases has, moreover, the additional advantage that it allows the patients a certain amount of freedom, which cannot be permitted if tannic acid has been used.

So far we have had the opportunity of employing the paste in only a few burns which involved the whole depth of the skin, but the results have been promising, as is illustrated by the following case:

Case 7 had a third-degree burn of the dorsum of the hand, which was treated with euglamide from the first. The natural coagulum separated on the fifteenth day and left a granulating area of healthy appearance; at this stage a culture gave a sparse growth of *Staph. aureus*. There was complete absence of oedema and of neighbouring inflammatory reaction, while movements of the tendons were free from the first. Pain was notably absent.

Our experience with another patient suggests that the paste may prove to be very valuable in the treatment of burns of the penis and scrotum:

On admission this patient (Case 19) showed very marked local oedema. The insertion of an indwelling catheter was contemplated, but since urine had been voided just before admission the procedure was delayed. The paste was applied, and the following morning the oedema, though still pronounced, was definitely less, and catheterization proved unnecessary. A steady improvement followed.



The paste has proved of value in burns which had become septic after the use of a coagulating agent; in these cases euglamide was applied to the unhealthy granulating surface remaining after removal of the coagulum, and rapid healing was promoted (Cases 16 and 17).

The history of Case 20 is interesting (see Figs. 1–4). This patient had second-degree burns of the right hand affecting the thenar eminence, a small area of the palm, and the second and third finger clefts from the web to the level of the distal interphalangeal joint. Tannafax jelly had been applied immediately by the medical attendant; six hours later this was removed at the casualty hospital and four-hourly saline compresses were ordered. When first seen by us one week later the condition was unsatisfactory: the patient complained of local pain, severe enough to keep him awake at night; the raised epithelium had been only partly removed from the burn and there was a considerable amount of dead skin left; the areas exposed were raw, tender, and inflamed; the blister on the palm was still intact; and movement of the fingers at the metacarpo-phalangeal joints was limited to 30 degrees of

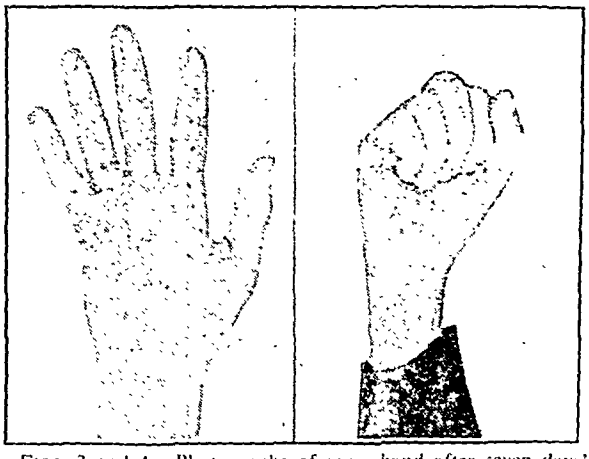


Table showing Results in a Series of Burns Treated with Euglamide

Case No.	Age (Years)	First-aid Treatment	Time elapsed till Admission	Nature of Lesion	Depth and Extent	Anaesthetic	Treatment	Days in Hospital	Remarks
1	1+	Boric ointment	30 hrs.	Scald	2nd and slight 3rd degree, left iliac fossa	Gas-and-oxygen	Cleansed; paste applied; reapplication every 3rd day	12	Application painless; non-irritant; early healing surface of tanned
2	6−	Soapy water and olive oil	1 hr.	,,	2nd degree, upper arm, forearm, and hand	,,	Cleansed; paste applied to upper arm and reapplied every 3rd day; other areas tanned	6 (tran to isolation hospital)	Remarks on Case 1 apply equally well
3	2−	Vaseline and starch	24 hrs.	Burn	Small 2nd and 3rd degree, buttock	None	Cleansed; fomentations applied for 24 hrs., then paste daily	6	An instance of rapid healing
4	1+	Olive oil and flour	1½ hrs.	Scald	2nd degree, chest, shoulders, and neck	Gas-and-oxygen	Charcoal-silver nitrate jelly applied; removed on 10th day, since tan was moist and septic; acriflavine applied to one half of infected area, paste to the other. After 6 days the part with paste was healed, the part with acriflavine healthy but raw	22	Healing and antiseptic properties of the paste demonstrated
5	3−	Carron oil	1 hr.	,,	2nd degree, neck, chest, and shoulders	None	Cleansed; paste applied; reapplied every 3rd day	12	Satisfactory healing
6	1+	Tannic acid jelly	1 hr.	,,	2nd degree, pubis, vulva, thighs, left leg, and foot	Gas-and-oxygen	Cleansed; paste applied to foot; reapplied every 3rd day; other parts tanned	30	Foot healed by 16th day. Coagulum began to separate on 22nd day
7	5+	None	2 hrs.	Burn	3rd degree, dorsum, left hand	,,	Cleansed; paste applied; reapplied every 3rd day	Under treatment	Kept perfectly dry without any sign of local inflammation; on 13th day slight moisture apparent at edges; on 15th day the natural coagulum separated, leaving healthy granulating surface
8	4−	Tannic acid jelly	2 hrs.	,,	Extensive 1st, 2nd, and 3rd degree, involving ear, cheek, chin, neck, right forearm, left forearm, hands, and legs	,,	Intravenous plasma; cleansed; paste applied to face and left hand; other affected parts, including right hand, tanned	Under treatment	Left hand healed perfectly by 5th day; movements full; tan on right hand still adherent, with no sign of separation
9	34	None	4 hrs.	Scald	2nd degree, dorsum right foot	None	Cleansed; paste applied; reapplied every 3rd day	9	Almost healed by 6th day
10	11	Tannic acid jelly	28 hrs.	,,	2nd degree, right buttock	,,	Cleansed; paste applied; reapplied every 3rd day	8	Healed by 6th day
11	−1	,,	4 hrs.	Burn	2nd and 3rd degree, buttocks	Gas-and-oxygen	Cleansed, paste applied; reapplied every 3rd day	14	Very small area on right buttock still to heal on discharge; satisfactory healing considering age and site
12	1+	Olive oil	1+ hr.	Scald	2nd degree, left shoulder, arm, and chest	None	Cleansed; paste applied, reapplied daily	13	Some pain on application; a rather complicated case; scarlatiniform rash, etc.; 2 small areas still to heal on discharge
13	2+	,,	2− hrs.	,,	2nd degree, left side of face, scalp, and small area of chest	Gas-and-oxygen	Cleansed; paste applied; reapplied every 3rd day	12	Face healed by 5th day; very small area on chest still to heal on discharge
14	1−	?	17 hrs.	Burn	2nd degree, involving an area 4 in. in diameter over vertex of head and left auricle; 3rd degree of scalp just posterior to auricle penetrating to bone	,,	Cleansed; paste applied; reapplied daily	Under treatment	On 8th day all parts healed except area behind the ear
15	4+	Olive oil	1 hr.	Scald	Extensive 2nd degree, involving chest, abdomen, groins, thighs, left axilla, face, palm of left hand	,,	Intravenous plasma; cleansed, paste applied to left hand; other parts tanned	,,	Left hand healed by 9th day with full movement; no sign of separation of tan
16	7	None	1–2 hr.	,,	2nd degree, right forearm and both lower limbs	,,	Cleansed, tanned; coagulum removed on 10th day because of sepsis; paste then applied; reapplied every 2nd day	,,	Practically healed after 3 applications of paste
17	4	,,	1–2 hr.	,,	2nd degree, scalp and right shoulder	,,	Cleansed; tanned; coagulum over shoulder removed on 14th day because of sepsis; paste then applied; reapplied every 2nd day	,,	Practically healed after 3 applications of paste
18	3+	Tannic acid jelly	2½ hrs.	Burn	2nd degree, lower lip and under surface of lower jaw	None	Intravenous plasma; cleansed; paste applied; dressed every 2nd day	,,	Almost healed by 4th dressing
19	2+	Olive Oil	3½ hrs.	Scald	2nd degree, suprapubic area, penis, and scrotum. Very marked oedema	Gas-and-oxygen	Cleansed; paste applied as spread every 4 hours for 24 hours, then 3 times a day	,,	On day following admission oedema was distinctly less; by 6th day progress was rapid
20	19	Tannic acid jelly for 6 hrs., then saline compresses	1 wk.	Burn	2nd degree, right hand thenar eminence, palm, second and third finger clefts	None	Cleansed; blisters snipped and considerable dead skin removed; paste applied; reapplied every 2nd day	Out-patient	Healed within 7 days; movements free and full

flexion. All dead epidermis and inspissated discharge were now removed, the parts cleansed with normal saline, the paste applied, and the hand placed in the position of maximum function. After two applications pain was absent, movement of the fingers was free, and the raw areas had almost healed. Apart from illustrating the value of euglamide, the history of this patient demonstrates that saline treatment, like tanning, may lead to unsatisfactory results and thus to condemnation of the method.

FIGS. 1 and 2.—Photographs of hand (Case 20) seven days after being burnt. Treatment had been tannic jelly for six hours, then saline baths and compresses. Fig. 1, with extension of fingers; Fig. 2, attempted full flexion of fingers.

FIGS. 3 and 4.—Photographs of same hand after seven days' treatment with euglamide. Fig. 3, with fingers in extension; Fig. 4, with fingers in full flexion.

Discussion
